Note that the property inheres in the subject and is demonstrated of it by demonstration; it is not, however, properly speaking an accident in the way that accident is called the fifth predicable, or in the way that what is really distinct from the subject inheres in it and accidentally perfects it. Rather it is an accident taken as that which is extraneous, because it is outside the essence of the subject, arises from it, and is really identified with it, as is clear in the first book on the proper (*q. de proprio*). Although the Doctor in this place appears to speak of the property as a common accident, as Fuentes notes; nevertheless one must not doubt that this work is the Doctor's, as that same Fuentes establishes there. For in a similar matter regarding the book on the Prior Analytics, Fuentes himself (*q.3. art.5. diff.2*) reproaches our Faber for denying that those books are Scotus's on the grounds that they contain many things at odds with the books of the Metaphysics and the Sentences, and yet attributes them to the Doctor. I make the same objection here to Fuentes himself, and say, with Bargius cited elsewhere, that in these works Scotus for the most part spoke according to the common opinion, an obvious indication of which is that in these he says not "I say" but "it is said," whereas in his subsequent later works he clearly set forth his own opinion, defended by firm and subtle arguments.

Assertion. Concerning the property only what the name is, or what is signified by the term, must be foreknown. Scotus holds this with Aristotle in the places named, and it is proved: it is impossible that anything be shown concerning something if its name is unknown — for if the name is unknown, the thing signified by the name must likewise be unknown, as Scotus indicates (*q.4 of this book*) and Zabarella (*ibid. T.2*) and (*l. de tribus praecognitis c.3*), following Themistius, whom he cites, saying that the signification of a name is the beginning of inquiry; and I premised this in the Epitome (*l.1. q.1. art.1*). Now the property is demonstrated of the subject in the conclusion through its proper cause, as is clear in this demonstration: every rational being is risible; every man is rational; therefore every man is risible. Here risibility, which is the property of man, is shown of man himself through rationality, which is its proper cause. And so concerning the property what the name signifies is foreknown. Moreover, it is necessary to know the property in some way before it is demonstrated as inhering in its object in the conclusion. For it is a principle or a part that, together with the subject, constitutes the conclusion; but before we constitute the whole, we must have some knowledge of its parts. Therefore a nominal knowledge of it is had in advance and presupposed — I say nominal knowledge, because confused and indistinct knowledge of a thing is acquired before distinct knowledge of the same thing is generated. For a child knows what is signified by the word "horse," even though he does not know the nature of a horse distinctly. Likewise, we have knowledge of the name of non-being, but not knowledge of the thing, since it is nothing. Furthermore, what is sought is not presupposed to be, for otherwise the inquiry would be pointless, as Zabarella observes (*l. de trib. praecognitis c.3*). Now in a demonstration it is asked whether the property inheres in the subject, and it is concluded that it does inhere. Therefore concerning the property only what the name is is foreknown.

You will object, first, that according to Aristotle and Scotus in the present place, concerning the property what it is is foreknown. Therefore also concerning it whether it is is foreknown. The consequence holds because what it is presupposes that it is. For as is clear from (*2. Post. c.1*), the first question is whether it is, and the second what it is; and the prior precognition from (*1. Post. c.1*) is whether it is, and the posterior what it is. Therefore if concerning the property what it is is foreknown, then certainly whether it is is also foreknown of it. Granting the antecedent, the consequence is denied; and to its proof I say that what the thing is indeed presupposes that it is, but what the name is does not. It is urged, from (*4. Met. T.28*), that what is signified by the name is the true definition: therefore if concerning the property what the name is is foreknown, then equally what the thing is. One must reply, from the Doctor cited above (§. *Ad 1*), that sometimes the meaning which the name denotes is the definition of the thing and the true definition, as the philosopher maintains in the passages cited; but sometimes the meaning which the name presents is a description and

not the true definition of the thing, but is called the definition of the name, as is clear from what was proved in the proposed assertion.

You will object, second, that the same philosopher in (2. *Post.*) adds that definition is twofold: one he calls what the thing is, and the other what the name is, which he attributes to non-beings. But the property is a real being, since it springs from the subject, which is a real being. Therefore the property has a real definition, not a nominal one; and consequently it is foreknown as to what the thing is. I reply that the definition of the name belongs not only to non-being but also to being, which likewise possesses a true definition proper to it. As for Aristotle: I say that he does indeed assert that the nominal definition belongs to non-being, but he does not deny that it can be applied to being as well. Now the property, being a being, possesses both kinds of definition, the nominal and the real. The former is foreknown before the demonstration; the latter is not.

You will object, third, that what is conjoined in one of the premises with the middle term must be foreknown to be, as is clear regarding the subject, which is placed in one of the premises and foreknown to be. But the property is numbered with the middle term in one or the other of the premises, as may be seen in the demonstration adduced in the first proof of the assertion. Therefore concerning the property whether it is is foreknown. I reply that the property is considered in two ways: in itself, insofar as it is a certain entity, with no account taken of the subject in which it is; or relationally, insofar as it designates an order and relation to the subject in which it is. In the first way it is placed in the premises and connected with the middle term, and this foreknowledge does not differ from the foreknowledge of the premises. In the second way it is placed in the conclusion and conjoined with the subject, and its inherence or inexistence in the very conclusion is shown there. Therefore, as a property, concerning it whether it is is not foreknown, but it is proved to inhere in the subject — as Scotus seems to suggest in the place mentioned (§. *Contrà istam*). Nor is there any parity between subject and property, because the subject does not depend on the property, whereas the property does depend on the subject. Now any being is cognized as it is; and since the property inheres in the subject, it cannot be known without respect and relation to another, as Scotus rightly adds in the same place.

Mastrius and Bellutus named at the beginning of this article reject this reply, but then go on to say that concerning the property whether it is must be foreknown confusedly and indistinctly, and that Aristotle does not mention this because its inexistence in the subject is clearly shown in the demonstration. But this plainly conflicts with Aristotle and Scotus, as is clear to the reader of the text. For since the precognition of what the property is is a confused and indistinct cognition, as the Doctor writes in the passage cited just above, if a confused precognition of the same property whether it is is admitted, then without doubt both precognitions must be conceded to the property itself, since both are confused

and indistinct — which Aristotle and Scotus cited above teach to apply only to the subject, as will presently be evident.

Article VI. How Many Foreknowledges the Subject Has.

All, while they readily admit with Aristotle (*1. Post. T.1*) that concerning the subject it is foreknown that it is and what it is, nevertheless do not all understand in the same way the manner and sense in which this is to be taken, whether for the first or for the second precognition. For Cajetan, Toletus (*c. praesenti q.vn. Ad 5*), and others cited by the Conimbricenses (*q.3. art.3*), think the first foreknowledge that it is should be interpreted as referring to the actual existence of the subject, so that the subject must be presupposed to actually exist at the time naturally appointed for it. The opposite, however, is maintained by Scotus (*both here q.7 and q.3. univ. §. Dicitur, and also 4. distinit. 1. q.2. §. Ex his H.*), Sarnanus (*q.3. univ.*), Faber (*Theor. 2*), Conimbricenses just cited, and others commonly and unanimously, who teach that the actual existence of the subject need not necessarily be presupposed, but that possible and potential existence — or the absence of repugnance to existing — is sufficient. Regarding the second foreknowledge of the subject, what it is, the dialecticians also dispute among themselves. For Zabarella (*l. de tribus praecognitis c.2*), with whom Toletus (*alleg. Ad 2*) seems to agree, understands and explains by what it is the meaning of the name; while Scotus (*3. dist. 14. q.2. §. Contrà infra H.*) and other authors named above protest, holding that concerning the subject what the thing is must be foreknown.

Note that this twofold doubt is raised with respect both to the total and adequate subject and to the partial and inadequate subject. The reason is equal in each case, since each is the base and foundation of the entire demonstrative edifice, and from it the demonstrable properties must necessarily proceed; and subjects are established as perpetual, necessary, and incorruptible, as I indicated in the first book (*q.3*). Hence the foreknowledge of the subject whether it is is not to be understood of its nature and essence — which, being necessary and eternal in objective being, is not presupposed to exist — but of possible and non-repugnant existence, as the Doctor rightly interprets (*in 4. praalleg.*), Bonetus (*1. Met. c.3*), Tataretus (*2. Post. q.1. dub.3*), and Sarnanus (*citat. pag.72*). The foreknowledge what it is, on the other hand, can be taken of the quidditative concept and of the definition: for demonstrations can be constructed from both, as is clear concerning being, which, lacking genus and difference, has no definition, yet possesses a quidditative concept, and of its properties are demonstrated, as I showed at length in the Metaphysics (*l.2*). Likewise, God from (*3. q. prol.*) is the subject of Theology, and of him, since he is utterly simple, no definition can be given, though a quidditative concept can rightly be given, as is plainly established in the first treatise of our Summa Theologica.

First Assertion. The prior foreknowledge of the subject that it is must be understood of its possible existence. So Scotus cited. Proof, first, from (*2. Post.*

T.21) and (*7. Met. T.20*) and elsewhere, where Aristotle writes that a demonstration whose middle term is a definition is about what does not exist. Therefore, according to Aristotle, the first foreknowledge of the subject is to be taken of possible existence. Second, the object of science is necessary, from (*1. Post. T.5*) and (*28*), and universal, from the same place (*T.29*). But the universal abstracts from all existence, since existence is contingent and a principle of change, which is alien to the notion of science; indeed science itself abstracts from all existence, from (*2. dist. 3. q.9. §. Ad quaest. B.*). Therefore concerning the subject only possible existence is foreknown.

Second Assertion. By the posterior foreknowledge of the subject, what it is, is understood what the thing is. The Doctor holds this in the place cited above and in the third place cited. Proof, first, from Aristotle (*6. Met. c.1*) and (*1. de anima T.11*), who says that the definition of the subject is the head and foundation of all science, and that the definition of the subject is the middle term of the most powerful demonstration. Therefore, according to Aristotle, concerning the subject what the thing is is foreknown. Second, that philosopher must be understood as speaking of the definition that generates science in us, since the scope of this work is to teach the method and provide the instrument apt for generating science; and it is the real definition, not the nominal one, that generates science in us. Therefore concerning the subject what the thing is must be foreknown. All the more so because, as Scotus says (*in 3. nuper alleg.*), and (*11. Met. in expositione Tex. c.1. Summa 3. n.54*), the entire notion of science is virtually contained in the notion and quiddity of the subject. Nor is the what it is acquired in any way by demonstration; indeed it is entirely presupposed, and through demonstration there is generated only cognition of the properties inhering in it.

You will object, first, against the first assertion, that Aristotle (*l. predicam. c. de Ad aliquid*) delivers that science and its object the knowable are correlatives that have mutual existence, and he adds that if science does not exist, the knowable cannot exist. Therefore existing science is of a subject that actually exists; and consequently concerning the subject it is foreknown that it actually exists. It is confirmed: the same philosopher (*2. Post. T.8*) adds that it is vain to ask what something is unless one first has that it is, since the latter includes the former. Therefore it cannot be demonstrated that a property inheres in a subject unless the subject is recognized to actually pre-exist. I reply that science and the knowable belong to the third mode of relatives, namely non-mutual ones; and therefore Aristotle says there that if the knowable is removed, science is also removed, but if science is removed, the knowable is not removed. For if the knowable does not exist, there is no science of it, for there will be absolutely no science of nothing. But if science does not exist, nothing prevents the knowable from existing. Hence I deny the consequence. To the confirmation: that passage must be explained not of actual but of possible existence, as is established from the note just given. You will press: the syllogism, which is a being of reason, is

considered by Logic as its object, and no possible existence on the part of reality belongs to it. Therefore the philosopher's assertion cannot be taken of possible existence. I say that possible existence in reality belongs to the object of real science; but to the object of rational science, such as the syllogism, only objective existence belongs. Just as in its own way definition is attributed to it, as Scotus (*in 4. cit. §. De 2. principali infra H.*) and Bonetus (*1. Met. c.2. §. Quarta proprietas*) say of second intentions in general.

You will object, second, that what is acquired through experience and the ministry of the senses is presupposed to have actual existence, because both experience and the senses deal with singulars that actually exist, as is more than evident; but science is generated by sense and experience, as the philosopher affirms at the beginning of the first book of the Metaphysics (*c.1*). Therefore actual existence of its subject is required. It is confirmed: science of God is about God himself actually existing as the subject of that same science, from (*3. q. Prol.*). Therefore the same must be asserted of the subject of any other science. Granting the major, I distinguish the minor. By accident and occasionally, by reason of the mode of knowing of this present state in which we must find every science by means of prior sense and experience — this I concede; through itself and absolutely, and of science already acquired — this I deny; as Scotus and Lychetus (*cit. q.3. Prol. §. Ad argumenta alterius*) seem to hold. The reason is that we possess the sciences of God, angels, and other things, which we learned from our predecessors by voice or writing, without that mode of cognizing. To the confirmation, one may say that the existence of God is altogether the same as his essence, as I showed with probability in the treatise on God the One (*disp.1*), while created existence differs from created essence formally and negatively.

You will object, third, against the second assertion, that Aristotle (*T.2 of this book*) expressly says that concerning the subject it must be foreknown what it signifies; but to signify pertains to the name, which is described from what was said in the Epitome (*l.2. q.1. l.2*) as a vocal sound signifying by convention, etc. Therefore concerning the subject not what the thing is but what the name is must be foreknown. This is especially so because the philosopher there wishes both foreknowledges to be assigned to the subject, the same ones he ascribed to the axiom and to the property; but he had expressly assigned to the axiom that it is, and to the property what the name is. Therefore he fits the same foreknowledges to the subject, otherwise he does not seem to speak consistently. Granting the major, to the minor it may be said, with Faber (*Theor.3. ad 1*), that not only the name but also the definition signifies; and therefore it is conceded by all that the name or the defined thing signifies confusedly, and the definition signifies clearly and distinctly. And Aristotle himself, explaining this, asserts that when (*T.70 of the same book*) he writes that the definition of the subject is the supposition of the science whose subject it is. To what is additionally urged, I say that just as whether it is is twofold — namely complex and incomplex — so likewise what it is is twofold, namely what the name is and what the thing is. The

incomplex whether it is belongs to the subject, but not the complex. Likewise the real what it is, and not the nominal what it is, is applied to the subject. Thus, just as the complex that it is, which is attributed to the axiom, does not befit the subject, so also the what the name is, which belongs to the property, should not be assigned to the subject. For since whether it is and what it is are established as general foreknowledges — as I noted together with Scotus above — they are subdivided into special ones, of which one belongs to the principles, another to the property, and both, in the manner befitting each and as explicitly stated, are ascribed to the subject.

Article VII. Whether the Subject Can Be Demonstrated in Science.

The principal positions to be recorded in this article are these: the first is that of Niphus (*1. Met. q.1*), Zabarella (*l. de trib. praecognitis c.9*), Raconius (*disp.1. de demonstratione art.3. proposs.*), and before them Bonetus (*1. Met. c.3. §. Septima proprietates*), who deny that the subject can be demonstrated in any way in the science of which it is the subject. The second is that of those whose names Zabarella suppresses, who hold that the subject can be demonstrated a priori in science, from whom Bassolis (*q.3. Prol. §. Ad rationes*) and Tataretus (*2. Post. q.1. dub.2*) do not seem to differ. The third is the nearly common position of Scotus (*q.3. Elench. §. Ad aliam quaest.*) and (*q.3. Prol. §. Ad 1. argum. V.*), Faber (*Theor.2*), and others, both of the Scotistic and Thomistic schools, who hold that the subject of a science can be demonstrated a posteriori by that very same science of which it is the subject.

Note that the principles pertaining to science are twofold, as Orbellus (*1. Met. c.1*) notes with Scotus' assent (*q.3. Prol. §*) — complex and incomplex. The former are called principles of knowing, because nothing in the science is more known or more evident than they, through which things are demonstrated, since they are themselves indemonstrable, at least in the science of which they are principles. Hence they are called first principles and doorways of the sciences, according to that saying of the philosopher (*2. Met. c.1*): who will err at the doorways? The latter are called principles of being, because from them as essential parts the subject of science is constituted — as the natural body is composed of matter and form as its intrinsic and essential principles. The former are necessarily required for constructing demonstration and causing science, because by them the properties are demonstrated of the subject; the latter are not always required. For the subject of a science can exist even without principles of being, as is clear concerning being, which is the subject of Metaphysics and exists without principles of being. Likewise concerning God, who is the object of Theology, of which there are many parts, as Scotus writes in the place cited above, followed by Zabarella (*citat. c.2*). It is therefore not necessary that the subject of a science have principles of being, but only principles of knowing, from which the inherence of the property in its subject is shown in the conclusion deduced and caused from them. Furthermore, it is presupposed

from what will be said in the following question that there is a twofold demonstration: because and propter quid, or a posteriori — which is through the effect — and a priori — which is through the cause.

First Assertion. The subject of a science cannot be demonstrated a priori by that very same science of which it is the subject. The Doctor clearly implies this (*q.3. Elench. in solution. 1. rationis*) and presupposes it elsewhere, and Zabarella names the contrary position vacuous and ridiculous and entirely without reason. Proof, first: what is demonstrated a priori is demonstrated from superior and more known things, as is established from Aristotle's definition of demonstration. But nothing is prior or more known than the subject of a science, since it is the primary root, the first item of consideration, the underlying substratum and receptacle of all things that pertain to that science in any way whatsoever. Therefore the subject cannot be demonstrated a priori. Second: what is demonstrated a priori comes into question and is shown to be through its proper cause, as no one denies; but the subject is presupposed and foreknown, not what is sought and unknown, as is clear from the assertions above. Moreover, in every demonstration there are three terms — major extreme, minor extreme, and middle. Now the subject is not the middle, because it would be shown through the middle; nor is it the major extreme, which is the predicate. And it is repugnant for the subject to be the predicate, and for what by itself underlies to inhere in another. It remains, then, that it is the minor extreme in the conclusion, which is not what is demonstrated but that about which something else — namely the property — is demonstrated as concluding to inhere in it. Furthermore, in demonstration three things principally intervene: the axiom, the subject, and the property; and just as the axiom and the property cannot be the subject, so likewise the subject cannot be the property or the axiom, since from what has been said it is foreknown whether it is and what it is, and consequently it cannot be demonstrated a priori.

Second Assertion. The scientific subject can be demonstrated a posteriori, whether it be partial or total. The first part concerning the partial subject is Scotus's in the place cited above, and is proved from the philosopher as cited by the Doctor there, who shows that the sophistic syllogism is demonstrated through similarities (*1. Phys. T.80*), that matter exists through form which cannot be without it (*1. Caeli c.4*), that the heavens exist through circular motion, that elementary fire exists through upward motion, and in the Metaphysics that abstract substances exist, etc. Second: through an effect the cause can be demonstrated; indeed philosophy began from cognition of effects and ignorance of causes, as the Stagirite notes (*1. Met. c.2*); philosophers were moved to inquire into water. And there are some effects necessarily conjoined with their causes and principles, as is clear from the motions of the heavens, the influences of the stars, and other such things that daily experience supplies us with. Therefore the partial object of a science can be demonstrated a posteriori. The second part, which is Scotus's (*both in prol. cit. and also 1. Met. q.1*), is proved, first,

from Aristotle, who in (2. *Phys.*) demonstrates a posteriori that a natural body — which is the total subject of Physics — exists through motion. And the same is implied (6. *Phys.* T.32). Second: God is the total object of sacred Theology from the Prologue cited, and is demonstrated a posteriori by it, as is clear from Scotus (1. *dist.*2. q.2). And the sacred pages confirm this, especially (*Sap.* 13): From the greatness of beauty, the creator of these things can be seen by comparison. The same is urged by the authorities and reasons adduced to prove the first part of this assertion. For the reason is equal in both cases. Just as the partial object possesses some effects necessarily conjoined with itself, as was established above with many arguments, so the total subject has some proper effects necessarily connected with it, through which it can be demonstrated a posteriori, as has been shown above concerning the natural body. Hence Mastrius and Bellutus are refuted, who (*disp.*12. q.2. art.2), while they receive this entire doctrine, nevertheless conclude that if science is taken strictly for cognition of the conclusion produced through the most powerful demonstration, neither a priori nor a posteriori can its subject be demonstrated. For that it cannot be done a priori is sufficiently proved in the first assertion; but that it can be done a posteriori is efficaciously urged by what I adduced to establish and confirm this second assertion. Nor should the subject of a science acquired through the most powerful demonstration be excepted, since Aristotle and Scotus in the places mentioned speak universally of the subject of science demonstrable by the Posterior Analytics; especially because these more recent authors extend and broaden to every total and partial subject, and illustrate with examples from Physics and Metaphysics, whose subjects are plainly demonstrable — and these are the preeminent sciences, especially Metaphysics, which is not undeservedly called the queen of the sciences. Now just as in the compositive method one proceeds from the known cause to the unknown effect, so in the resolute method one proceeds from the known effect to the unknown cause. And since several properties spring ordinately from a single cause, one presupposing and presupposing another — as in the case of wonder, risibility, and admirability in man, all proceeding from rationality — beginning from the first property, passing through the intermediate ones, we are able to arrive at the last demonstration of the subject in which they inhere, as Orbellus expressly pursues (1. *Met.* c.1. §. *Ad enim evidentiam*). And so a posteriori demonstration of the subject of science taken strictly is constructed. For this reason the philosopher (c.2 of this book) and (2. *de anima* c.2), by the a posteriori definition of the soul, shows its a priori definition, and vice versa, as I showed plainly there. Without reason, therefore, and resting on no foundation, do the aforementioned more recent authors deny this of the subject of science had through demonstration, while they affirm it of the subject of any other science — and unwittingly they slide into the position of Zabarella and the others whom they attack. The passage of Aristotle (T.2 of the same book) adduced by them — namely that concerning the subject what it is is foreknown and not demonstrated — is understood a priori and not a posteriori, as nearly all of

Scotus's disciples interpret it, with whom the Conimbricenses (*q.3. art.3*) and not a few other ancient and modern philosophers agree.

You will object, first, against the second assertion, that some subject of some science possesses intrinsic and essential principles from which it is composed, as is clear from the note just proposed. Therefore through them such a subject can be demonstrated a priori, since those are its constitutive causes and parts, as is clear of matter and form, which constitute the natural body, which is the subject of Physics. Granting the antecedent, I deny the consequence. For although such principles can be shown a posteriori — that is, through some natural effects which are more sensible and closer to the senses — nevertheless, since they have no cause a priori, they cannot be demonstrated. If you infer that at least the subject can be proved a priori through them, because they are its intrinsic causes, the response is first that a priori demonstration is made from what is more known, more evident, and causative of the conclusion — not from principles of the subject, which pertain to its definition. And the definitions of subjects or substances are indemonstrable, as is clear, because they are the suppositions of sciences; and this is the expressed mind of Aristotle (*2. Post. c.4*), (*1. Top. c.1*), and (*6. Met. c.1*). All the more so because demonstration shows the property inhering in the subject, not the cause and intrinsic principle of the subject itself, as Zabarella accurately observes in the place named.

You will object, second, against the second assertion, that what is a supposition and foreknown in science is not what is sought and unknown; but the subject in a science is a supposition and foreknown from (*T.1 c.1 of the first Post.*) — indeed it is the foundation and root of all things considered by science. Therefore the subject of a science cannot come into demonstration, even a posteriori; otherwise the same thing would be both supposed and sought, both known and unknown, which involves a manifest contradiction. Granting the major, to the minor I say that this and similar arguments adduced by proponents of the opposing opinion are to be interpreted a priori, not a posteriori, in accordance with what I maintained and proved in the two preceding assertions.

You will object, third, that it is the function of whoever considers the existence of a thing also to consider its essence, because existence follows on essence as its mode; but it belongs to Metaphysics to examine the essences and quiddities of things, since it is the most universal science. Therefore it likewise belongs to that very same discipline to examine and prove the existences of essences; and consequently no particular science demonstrates the existence of its subject a posteriori. Granting the major, the minor must be distinguished: with regard to common and transcendental notions — I concede; with regard to particular and proper notions — I deny. For since each particular science is a distinct science, it has a distinct object with which it is occupied. And therefore Metaphysics does not contemplate the proper objects of other sciences either as to their essence or their existence, nor does it intermingle with them, as will be more apparent

from what I shall commit to writing in the first and second books of the Metaphysics.

Article VIII. Whether the Subject Virtually Contains All the Truths of the Science of Which It Is the Subject.

The definition of the scientific subject offered by Scotus (*q.3. Prol. §. De 2. B.*) in these words — The notion of the primary subject is to contain in itself primarily and virtually all the truths of that habit of which it is the subject — is attacked, though not overthrown, resting as it does on a most firm foundation and fortified with the strongest reasons; it is attacked both against Outsiders who endeavor to undermine it, among whom are numbered Auriol (*in prol. artic.1. pag.17*), Gregory (*ibid. q.4*), Bacon (*q.3*) together with Ockham (*in loco q.9*), and Cajetan (*1. part. q.1. artic.7*); and also against Our Own, who dispute not a little about which subject is intended and in what sense it is to be explained. For some, like Canonicus (*q. prima 1. Phys.*) and Orbellus (*ibid.*), apply it to the generic and specific subject; others, like Faber (*Theor.5*), concede that it applies only to the specific subject. Nor is the dispute less among the same authors about the very containment of the subject's truths: some, like Bargius (*q.3. prol.*), hold that the truths are contained in the subject in real being; others, like Vigerius (*ibid.*), that they are contained only in cognitive being; and still others, like Lychetus (*in Commentario*), that they are contained precisely with respect to their evidence. What must be said by us in accordance with truth and Scotus will be made clear through what we shall set forth.

Note first and recall from what was said in the first book (*q.3. art.1*) that what science is occupied with has several names and requires several conditions, concerning which the Doctor does not seem to have spoken in the same way in all his writings. For in (*q.3. univ. §. Dicitur*) he enumerates only three conditions required for the subject of science; but in (*q.2 of the first Prior*) he attributes six to it. Then in (*1. Reportat. q.1. Prol. §. Dicitur*) he describes the subject as what determines and dignifies the science, and is said of other determinate things in the science — which are, in rectus or in obliquus, as Mauritius (*q.3. univ.*) and Maior (*l. praedicabilium q.3. not.3*) explain. But in (*6. Met. q.1*) and (*q.3. Prol.*) he defines the subject in the way I stated at the beginning of this article, which he repeats (*3. dist.36. q.vn. §. Quantum ad istum L.*) and in other places of his doctrine. Although this diversity of texts of the Doctor is found in his works concerning the total and adequate scientific subject, no contradiction is involved, but rather one text can rightly be explained by another, or one included in another, or one reduced to the other. For those six conditions of the first Prior are gathered into the three delivered in (*q.3. univ.*), as I showed in the place cited (*propositione 2*). And these three are indicated in the description of the subject from (*q.3. Prol.*). For what adequately contains virtually all the truths demonstrable of it is foreknown whether it is and what it is, and properties are demonstrated of it, and all things treated in the science are reduced to it. Likewise it accords well

with what Scotus adds in (*Reportat. primi, q.1*), since it is the common sense of philosophers that science is determined and specified by its object; and with one voice all philosophers together with Aristotle (*1. de anima c.1*) and (*6. Met. c.1*) proclaim that from it science derives its dignity and nobility — and Scotus cites these in (*prol. q.3. §. Ad 1. T*).

Note second, from the Parisians (*1. Phys. q.4*) after Scotus (*mox cit. §. De 2. B.*), that just as that is called the first being which does not depend on another but other things depend on it, so to contain primarily signifies nothing other than not depending on others while others depend on it — so that the second depends indeed on the first, but not the first on the second. And if by the impossible anything else were removed, while the subject itself remained, such a subject would still virtually contain all the truths knowable about itself, so that such truths are comprehended nowhere except in that same subject. Now primarily is taken here for the primacy of adequation, of which Aristotle speaks (*1. Post. T.11. 14*), so that to contain primarily is the same as to contain adequately, as Scotus notes in the place cited above. Furthermore, for a more convenient understanding of this, Scotists observe that there is a multiple containment. The first is called essential containment, by which one contains another in the first mode of speaking per se — thus the defined contains its definition, and the inferior contains its superior. The second is called unitive containment, by which one contains another really identified with it but formally distinct — in this way the subject contains its properties and the soul its powers. The third is potential containment, by which a superior contains the properties of its inferiors — thus animal contains the properties of man and of brute. The fourth is virtual containment, by which the container can produce the content in being; and this is subdivided into that by which the container can produce the content in being simply, or in the being of real existence, and into that by which the container can produce the content in qualified being or in cognitive and diminished being. The former kind of virtual containment is effected in two ways: either through motion and change, and in this way container and content, producer and produced, really differ — as God and creature, father and son; or through simple emanation and springing forth, and in this way container and content differ formally only — as God and his attributes, subject and its properties. The latter kind is also had in many ways: either in cognitive and effective being, as the intellect is said to contain the object virtually in cognitive being, producing its cognition, whether the object be substance or accident; or argutively, as an accident contains the species of substance, because through cognition of the accident we come to cognition of the substance, according to that saying (*1. de anima T.11*): accidents contribute greatly to knowing substance; or a posteriori, as an effect contains the species of its cause; or terminatively, and this happens in two ways — either adequately and totally, as an object contains the evidence of a thing in cognitive being, since although cognition is generated by the object and the power as two partial causes constituting one

total cause, nevertheless evidence is precisely and totally caused by the object; or it is terminative in another mode. The fifth containment is eminent, by which one is said to contain another in a more perfect mode than it is in itself, which, though in God it coincides with virtual containment, does not in creatures identify with virtual containment — as is clear of gold, which eminently contains silver though it cannot produce silver. Now the truths that the subject of a science contains are, according to the Doctor in the Prologue cited, of two kinds: immediate and mediate. Among the immediate, some consist of the subject and its definition — as man is a rational animal — and such truths the subject contains essentially and equally; while some are made up of the subject and property — which are called immediate by immediacy of cause, because their immediate cause is assigned — as rational is risible. The mediate truths are those constituted of subject and property which are said to be mediate because their immediate cause is not given, as man is risible. We speak here, however, of intrinsic properties, which besides the subject denote nothing else extrinsic; not of extrinsic properties, which always regard something extrinsic — as eclipsability of the moon, beatifiability of a rational creature — as the Parisians cited above and other Scotists rightly note for the solution of the arguments of Ockham, Gregory, and the other Nominalists.

Note third, from the Doctor in the question of the Prologue cited (§. *Contrà istud D.*), that science, being certain and evident knowledge of the intellect about an object, does not receive all its constitutive elements from one and the same source. For as knowledge it has them from the intellect and from the object as two of its partial causes constituting one total cause. But as certain and evident, it derives them only from the object. For as soon as the intellect conceives the essential relation of the predicate to the subject, immediately by the force of the terms the proposition becomes certain and evident. Wherefore, when we say that science is caused by a cause evident to the intellect, we are not speaking of science as knowledge — for in that sense it is generated by the intellect — but of science as certain and evident; for in this way it is caused by a cause known to the intellect, since nothing is known through what is unknown. Similarly, when science is said to be the effect of demonstration, this is explained in terms of the evidence of truth, not absolutely in terms of knowledge, which principally depends on the intellect. In demonstration properly speaking, moreover, it is not the conclusion that is demonstrated, because it is not predicated of the subject, but rather what is properly demonstrated is the inherence or relation of the predicate to the subject through the middle term, which is the definition of that same subject; so that, when the cause is posited and all else removed, such a relation is posited, and when the cause is removed, the relation is taken away. For this reason the subject, including formally and essentially its own definition — which is the precise cause of the inherence of the property — adequately and virtually contains the truth, evidence, and certitude of such a proposition. And therefore truth and knowledge are not the same thing: for knowledge is a

certain quality, in whose essence a relation is not included; but truth is a relation of conformity necessarily arising from the composition of terms, as I showed in the preceding book in the question on truth.

Note fourth, from the Doctor in the question of the Prologue cited (§. *Contrà istud D.*), that just as an object can be compared to two things — either to the power whose object it is, or to the act and habit produced by that same object — so it can bear two mutual proportions to them: one of a mover to the movable, or of the active to the passive; another of a cause to its effect. The first proportion consists in this: that as the object moves the power by producing something in it, so the power is moved by the object by receiving something from it, namely the species. The second proportion is situated in this: that as the object causes the act and habit, so the act and habit are partially caused by that same object. Between these two proportions there is this difference. First, the extremes of the first proportion regard all things contained per se under those extremes. The reason is that when some agent acts on some patient, any agent of the same kind can act on that patient, and conversely, because a patient that can be acted on by some agent, any patient of the same kind can be acted on by that agent. Hence from all actives of the same kind a single concept predicable of them can be abstracted; and likewise from all passives a single concept can be abstracted that is predicable of them: for example, because this color can be seen by the visual power, in like manner every color can be seen by the same power; and conversely, because this visual power sees this color, consequently all other visual powers can see this color. But this does not happen in the second proportion; nor in it can such a common concept be abstracted, nor does it follow that, as the common object can cause the evidence of an adequate act or habit, so also this object contained under that common one can in like manner produce such evidence. The reason is that the cause of evidence is found per se primarily in that common thing, not in the particular contained under it. And so, for example, Peter is risible because man is risible, to whom risibility per se belongs, as is drawn from (1. *Met. c.1*).

Note fifth and recall from what was said in the first book that the unity of a science is derived from the unity of the genus of the subject, which has parts and properties, as Aristotle (1. *Post. T.19*), (4. *Met. T.2*), and Auriol (*art.1. Prol. pag.56*) clearly state. This is understood of generic science, because its object is generic, by which it is partially caused. The same the Doctor delivers in the Prologue cited (§. *De tertio sub D.*) and more expressly (3. *dist.25. q.2. §. Ad 2. C.*) and (*dist.36. q.vn. §. Quantum ergo L.*) and in (*Reportat. 3. dist.25. q.vn. §. Sed quaeritur*) and also (6. *Met. q.1*). Since, moreover, the Doctor in the same Prologue cited establishes a twofold science — generic and specific — there is equally a twofold scientific subject — generic and specific — and consequently a twofold definition: one accommodated to the generic subject, the other to the specific subject. Now the generic subject is commonly described as that which potentially contains the truths demonstrable of it — and I noted above that this

is not inappropriate, since genus is a certain potential whole, as I showed elsewhere, containing its inferiors potentially. For this reason such a generic subject is said to comprehend the truths knowable of it potentially. The specific subject, on the other hand, is that which per se primarily contains virtually the truths demonstrable of it, as I noted above. Between these two descriptions the only difference is that the generic contains and the specific receives its truths virtually. Now virtual containment can be employed in two ways: in one way broadly, as it coincides with remote and potential containment — thus the Doctor took it in the places just cited and in the Reportatio, as some more recent authors explain, following Orbellus (*1. Met. c.1. §. Ad 2.*) and (*6. eiusdem operis c.1*) and Brasavolus (*q.3. universalium*). In the other way strictly, for proximate and immediate containment — and this belongs only to the specific subject, and seems to be the definition of the subject adduced at the beginning of this article, as Auriol (*in Prol. paulò antèar.2. pag.57*), Faber (*Theor.c.*), and many others interpret it.

First Assertion. The adequate subject of a science is aptly described as that which in itself primarily contains virtually all the truths of that habit of which it is the subject. The Doctor expressly holds this (*in prol. memorato q.2. lat. §. De secundo sub A.*), and all his interpreters in the same place approve it, and it is proved in two ways. First: what contains all immediate and mediate propositions virtually contains all the truths of the science of which it is the subject, because there are no knowable propositions other than immediate and mediate ones; but the adequate subject of a science contains immediate propositions because the subject of these contains the predicate and their evidence; and immediate propositions contain mediate ones, namely conclusions. Therefore the primary and adequate subject of a science contains the truths of the science of which it is the subject. Second: the adequate cause of some effect virtually contains that effect, as is clear from the second note. But the subject is the adequate partial cause of the habit of which it is the subject, according to that well-known saying: from power and object knowledge is born. Therefore the primary and adequate subject is rightly defined as what virtually contains all the truths of the science of which it is the subject. Especially because, since from that subject several properties spring forth in orderly fashion, one being demonstrable through another, all the way back to the first which springs immediately from it — as I implied above from Orbellus (*1. Met. c.1*) — such is the adequate subject of a science as was described above.

Second Assertion. The definition of the subject given by Scotus in the Prologue cited and adduced by me at the beginning of this article, while it properly belongs to the specific subject, can nevertheless be extended to the generic subject. This assertion comprises two parts, through which the entire dispute among the Scotists seems to be reconciled and settled. The first part is proved, first, from the Doctor (*cit. B. 3. dist.14. q.1.1*), who, in explaining how the primacy of the object containing virtually is to be understood, adds that the primacy

here is to be taken in nearly the same way as it is taken in (*1. Post. T.11. and 14*) in the definition of the universal — that which is a posteriori, adequate, and convertible with its properties, which is precisely what the specific subject is; for the generic subject is not adequately reciprocated with the properties of its inferiors, since one cannot validly say it is an animal, therefore it is risible, because risibility is not its adequate property, and the inference of subsisting does not convert from one to the other. Therefore the aforesaid definition belongs only to the specific subject. Second, the same Scotus (*ibid. D.*) asserts that between the object and the act and habit, whose evidence the subject is said to contain virtually and adequately, the proportion is that of a cause to an effect — assigned solely to that cause which per se primarily contains the notion of that effect; but the generic subject is not of this kind with respect to the properties of the inferiors, which are contained in it only potentially. Therefore it must be the specific subject. I add that the genus is a potential, confused, and imperfect whole, as is clear from the question on genus; therefore it contains the properties of its species only potentially and imperfectly, and so proper and proximate virtual containment cannot aptly be attributed to it. You will say: why does the Doctor not provide a definition of the generic subject? It may be said because such a definition does not pertain to the matter he discusses there, for he discusses there the object of Theology, which in no way is generic. Also because from that definition the definition of the generic subject can easily be derived, as the same Doctor does in a similar case (*ibid. q.4*), defining good praxis but not praxis taken in general — just as I observed that Porphyry did nearly the same concerning difference in the Epitome (*l.1. q.3. 4. 5. ante n.11*). The second part is proved, first, from Scotus (*1. d.3. q.3. §. Quantum, ad 2. a.*), (*q.7.*), and elsewhere, and also (*quol.7. N.*), affirming that being is the primary object of our intellect, virtually containing its properties demonstrable of it; but being is not a specific object, since it is transcendent. Therefore, according to Scotus, virtual containment belongs not only to the specific object but also to the generic and other objects. Second, the same Doctor (*6. Met. q.1*) expressly teaches that virtual containment belongs to the generic subject, and not obscurely implies this (*1. Post. q.vlt. §. Ad id q.*) and (*3. dist.36*), adducing the example of Geometry, which not being one in species, does not have a specific subject in which its truths are virtually comprehended. And again in (*dist.36 of the same book*) he repeats this same thing of Geometry, prudence, and the objects of other habits. Furthermore in the Prologue cited, not unmindful of the specific and generic object before E, he provided no other definition beyond the one delivered, which is an indication that the generic object was comprised under that one definition, in nearly the way I set out in the last note. Finally, because he must conform to Aristotle, who (*1. Post. c.23*) speaks of the generic subject, as Auriol cited rightly notes, and Scotus seems to hold (*1. Post. q. alleg.*).

Third Assertion. Although the subject virtually contains its properties both in real being and in cognitive being, nevertheless its notion as primary object is not

well explained through either of them alone. The first part, which Scotus (*loco nuper citato*) favors, is opposed to the Nominalists adduced at the beginning of this article, and is proved, first, as to real being: to contain virtually as such is to be able to produce something in being of existence, either through motion and change — as a father produces a son — or through simple emanation — as the subject produces its property, inasmuch as at the positing of the subject the property necessarily emanates and springs forth. Therefore the object virtually contains its property in real being. Second, it is urged as to cognitive being: a thing stands in the same relation to being known as to being, from (2. *Met. c.1. T.4*); but the property depends on the subject in being. Therefore also in being known — if not adequately simply speaking, at least adequately objectively — since its cognition is produced by the object and the intellect. The second part is opposed to certain Scotists, notably Bargius and Vigerius cited, and is proved, first, from Scotus cited, who situates the notion of the subject in its ordering to the science of which it is the subject. Therefore virtual containment, in accordance with which the notion of the subject is posited, does not bear on its real incomplex being but on complex truths; and thus the notion of the subject is not well explained according to the real being of the property produced. Second, from the same: the subject contains all truths, both immediate and mediate, of that habit of which it is the subject; and so the virtual containment of the subject is not considered in terms of its real incomplex being. Nor is it similarly understood in terms of cognitive being: for the Doctor there does not say that the subject primarily contains cognition or habit, but that it contains truths virtually; but truth is not cognition but evidence and certitude of cognition, as was said above. Therefore it is not rightly declared through cognition alone, whether actual or habitual. Furthermore, the Doctor in the same place, examining more openly what is meant by the truth virtually contained in the object, adds the reason that the subject contains the predicate and the evidence of the entire proposition; but evidence formally is not cognition but adds to it the necessary relation or conformity of contents. And shortly after (§. *Contrà istud D.*) he rejects the proportion of cause to effect between the primary subject and its act and habit, because virtual containment of truths is only in the primary and common object, not in the particular object — which pertains to the evidence and truth of the habit. Wherefore the virtual containment of the primary and adequate subject regards not cognition but the evidence of its propositions. Added to this: the precise and formal notion of something must be adequate and intrinsic to it, such that, when it is posited, its effect is posited, and when it is removed, its effect is removed — and this cannot be prevented even by the absolute power of God. Therefore virtual containment, insofar as it precisely tends to knowledge, cannot be the formal notion of the scientific object, since all cognition — not only actual but also habitual — can be immediately produced by God independently of the object; but the formal notion of the object, being intrinsic, can in no way be supplied.

You will say that it can be supplied as to the moving of the object, but not as to the termination, because the former is accidental and the latter essential to the object, from (3. *dist.15. q.2. in fine*); and further, God indeed cannot supply the formal notion, but he can supply its effect. But this reply does not satisfy me. For to terminate a cognition is not the same as to contain it virtually, since termination is merely the simple relation of the attainment of the object by the power through the act in itself or in another; but to contain virtually is to be able to produce, as is clear from what was said above. Therefore our argument is not weakened by the reply adduced. Against what is additionally urged, I press thus: the formal notion of virtual containment is to be able to produce; but if God cannot supply the first, neither can he supply the second.

Fourth Assertion. The notion of virtual containment in the scientific object is aptly and precisely expressed through the evidence and truth — actual or habitual — of the science of which it is the subject. This assertion is conspicuously and accurately defended by Lychetus (*in comm. Prol. c.tato*), whom Bassolis and Rubionius appear to have taught before him, and whom Faber (*Theor.5. c.3*) follows against Bargius Pedemontanus, who stubbornly maintains and defends the opposite. Proof, first, from the passages adduced above in the preceding assertion, in which the Doctor plainly sets forth that the subject virtually contains the truth and evidence of the propositions of that habit of which it is the subject, and that it is the adequate cause thereof — just as the posteriori universal is with respect to its property. And all of this is said precisely of the evidence of the act and habit. Therefore the virtual containment of the primary and adequate scientific object is suitably declared through this truth and evidence. Second: truth and evidence is the adequate effect of the subject, not only in the genus of subject but absolutely. Therefore the notion of virtual containment of the object is well explained through the aforesaid evidence. The consequence holds because the formal notion of the subject, being intrinsic and distinctive of it from all that is not such, must be adequate and belong to it per se primarily. The antecedent is proved: truth and evidence, being nothing other than the conformity of predicate to subject, necessarily arises from nothing other than the intrinsic relation of one to the other, known by the intellect.

You will object, first, that a being of reason is not a knowable object, as is clear (1.1 *q.3. l. postremo Met. q.1*); but a being of reason does not virtually contain the truths demonstrable of it, because it has no power of producing them in real being or cognitive being. Therefore the definition of the subject assigned above is defective. Tataretus (*in proaemio Log. q.2. scibili 3*) easily extricates himself from this argument by saying that the definition given is to be interpreted of the subject of real science, not of the subject of rational science, such as the being of reason, which contains nothing virtually, neither in real being nor in cognitive being, neither partially nor totally, since production is an act of real being, which can belong only to what actually exists. It can perhaps be replied better that the aforementioned definition can also be applied to the being of reason,

because the being of reason in its own way possesses proper entity and only objective and intentional existence and causality, deriving principally from its foundation, and has proper properties demonstrable of it, as may be seen in the places mentioned just above.

You will object, second, that if the subject virtually contained its property, the subject and property would be really distinct — as between what produces and what is produced there is real distinction — and the subject is productive of its property, as Scotus does not deny in the place cited above; but that the subject is really distinct from its property conflicts with Scotus (*2. dist.16. q.vn.*), and I showed this at length in the *Metaphysics* (*l.2. q.2*). Especially because real distinction falls between things and things; but many properties are not things distinct from their subjects, such as creatability, corruptibility, and annihilability. Therefore it is wrong to assert that the subject virtually contains its properties. I deny the inference of the major. For this holds in productions through motion and change, not in productions through simple emanation, as the property proceeds or springs from the subject, as the Parisians note (*cit. in solution. 1.*) and I observed in the second note. Or better, in accordance with the last assertion, say that virtual containment of the subject is to be sought in terms of the truth and evidence of immediate and mediate propositions, not in terms of production of the incomplex in real being and in cognitive being. Through this distinction collapse the arguments that Gregory, Bacon, and the other Nominalists amass at length, as may be seen in Faber cited above.

You will object, third, that nothing created can virtually contain anything. Therefore the subject does not contain the truths knowable of it. The antecedent is proved: according to the common doctrine of theologians, whatever God contains virtually can be produced immediately by him alone as the primary and universal cause. I deny the antecedent; and to its proof I distinguish: as a simply effective cause — I concede; as an effective and objective cause — I deny. For God indeed contains everything creatable with effective containment, but not with objective containment. For the properties of creatures are not knowable through the divine essence but through the formal notion of the object from which they flow.

You will object, fourth, that if the subject virtually contains all the truths demonstrable of it, then matter — which is the primary subject of physical things — must be established as the subject of Physics; God, who virtually comprehends all things in his infinity, will be the subject of all sciences; and substance, which is the cause of cognition virtually according to (*4. Met.*), is without doubt the subject of *Metaphysics*. But these and similar conclusions are thoroughly absurd. Therefore, etc. I reply that these and similar arguments, which can be framed in this manner, conclude with respect to virtual containment in real being — not with respect to virtual containment of the truth and evidence of the scientific habit.

Question III. On Demonstration.

Article I. Whether Demonstration Exists and What It Is.

Nearly all philosophers, with the exception of the Sceptics mentioned by Raconius (*disp.1. sect.2. q.2*), teach that demonstration exists — particularly those who admit science, who are to be cited in the question on science (*art.1*). It is for the sake of science that demonstration itself was devised. For it is the instrument and cause of science; and from the existence of an effect to the existence of its cause there is a ready argument, as ancient and modern philosophers frequently employ in acquiring the sciences. Furthermore, the particular demonstrations offered in each individual science put the existence of this assertion beyond doubt. Presupposing, therefore, the existence of demonstration, we must carefully investigate its essence, which will become clearly known to us through its definition. Now two definitions of demonstration are adduced by Aristotle (*c.2. T.8*), of which the first is expressed in these words: demonstration is a syllogism that produces science — which, as the Doctor observes (*q.11 of the same work, §. Adq.*), is given through the final cause. For the end of demonstration is science, and every instrument is customarily described through the end for which it was devised, as the Conimbricenses imply (*q.2. ad finem art.1*). And so, since demonstration is the scientific instrument, it is rightly defined through its scientific end. The second is given in the same place: demonstration is from what is true, primary, immediate, prior, more known, and causative of the conclusion — which Scotus mentions (*both loco cit. and also 3. dist.24. q.vn. in fine §. Ad quaest. ante E.*). And this is delivered through the material cause. Just as a house is constructed from stones, lime, and other things necessary to it as its material components, so demonstration is put together from the items just described as from its material cause. Both are reported by Maior (*1. Post. fol.70*), who notes that one can be demonstrated by the other — the material by the final, for example — as I showed in a similar case in the second book on the soul. Into the same thing seems to fall that which Aristotle offers (*1. Top. c.1*) and the Doctor accepts in this book (*q. alleg. §. Item*): demonstration is from immediate things and from those that are immediate principles — though it is plausible that this is the definition of demonstration taken universally, fitting both the *propter quid* and the *quia* demonstrations, as the paired Scotists note (*2. p. Inst. Tract.1. c.2*) and the Doctor explains (*in fine q. cit.*): demonstration is from immediate things, resolving finally all demonstrations to first principles which are immediate. And so demonstration can absolutely be made from immediate or from mediate things; and it is commonly said to be from immediate things because, if it consists of mediate things, it can finally be resolved into immediate principles.

Assertion. The aforesaid definitions of demonstration are exact. So together with all interpreters of Aristotle, Scotus (*ubisupra*) and his disciples teach, defending them excellently against the objections of adversaries and fully

satisfying them. This assertion can be urged through a common and well-known argument. For those are considered good definitions that participate in genus and difference; and such are the definitions of demonstration just adduced. Therefore they are legitimate. Although the syllogism cannot be a genus to the topical and analytic, as I proved (*q.1. of this book art.2*), and Zabarella does not dissent (*in com. T.8. and l. de speciebus demonstrationis c.1*), it nevertheless performs the function of genus in the first definition; in the second it is implied; and the remaining particulars hold the place of the difference, which constitutes demonstration in its essential being and distinguishes it from everything that is not demonstration, as any other quidditative and essential difference does.

You will object, first, that a suitable and exact definition must fit everything defined, as the laws of a good definition require; but to be a syllogism productive of science — which is the definition of demonstration — does not fit every demonstration, namely demonstration quia, which, not being from the cause as science requires according to Aristotle's description, cannot consequently be its effective cause. And so the definition of demonstration is not rightly given. Granting the major, to the minor I say that the definition given fits only the propter quid demonstration, which is called by the Doctor at the end of the question demonstration simply speaking. And the same must be asserted of the definition of science, as Tataretus explains (*q.2. art.3*) and Zabarella elegantly sets out (*loco ultimo citato*).

You will object, second, that science is generated by the knowable object and the intellective power as two partial causes constituting one total cause, according to the common position of philosophers. Therefore it is wrong to place in the definition of demonstration that science is the effect of demonstration. Granting the antecedent, I deny the consequence. For the efficiency of the object and of the intellect is presupposed for causing science; and once that is had, the intellect forms the necessary propositional premises, which are the efficient causes of the conclusion.

You will object, third, that nothing superfluous and nothing deficient ought to be placed in a definition, as was established through the canons of definition adduced in the Epitome (*1.2. q.7. art. ult.*). But in the second definition of demonstration there are certain things that appear superfluous and empty — namely primary and immediate. For what is primary is immediate, and what is immediate is primary. Again, demonstration is said to be from prior and more known; but the immediate is prior and more known. Therefore that definition of demonstration is not correct. Granting the major, I deny the minor. For, as the Doctor says, not all principles are immediate — for example, this proposition is per se primary: man is an animal — yet it has a middle term through which it is demonstrated, namely through sentient. It is therefore rightly appended to demonstration that it is from first and immediate things, as the Conimbricenses likewise interpret (*q.2. art.3*). To the further point urged, I

say with the Doctor that principles in themselves and absolutely are first and known; but they are called prior and more known with respect to the conclusion, which is posterior and less known.

Article II. How Many Species of Demonstration There Are.

This difficulty is treated fully and learnedly by Zabarella (*l. de speciebus demonstrationis*), where through many chapters he is entirely occupied in untangling and developing it, by Faber (*Theor.10. 11*), Mastrius and Bellutus (*disp.13. q.1. art.2*), and many others who enumerate three principal positions. The first is that of Avicenna and others cited by our more recent authors, who hold that there is only one species of demonstration, called demonstration propter quid. The second is that of Averroes (*1. Post. com.95*) and his followers, who admit three species of demonstration: the demonstration that or quia, the demonstration propter quid, and the demonstration that and propter quid simultaneously. The third is that embraced by Scotus (*quol.7. §. Hic praemittenda sunt A.*), Gadius, Lychetus (*ibid.*), Zabarella cited, and others commonly, who assert that there are only two species of demonstration: the quia and the propter quid. For its more easy and convenient understanding:

Note first that there are four principal divisions of demonstration. The first, which Scotus (*1. Post. q.13. §. contra istud*) and (*q.34. §. unde*) reports from Aristotle (*ibid. c.18. T.49*), is into universal and particular; and this, as Auriol notes (*1. d.35. a.4*), is derived from the universality and particularity of the subject. For the universal is had of a universal subject, the particular of a particular subject. The second, from the same Doctor (*ibid. q.21. §. Adq.*) after Aristotle (*in the same work c.19. T.40*), is into affirmative and negative — which from what was said in the Epitome (*l.2. q.2. q.3*) is plain. The former is more worthy and excellent than the latter, as the philosopher likewise asserts there, both because it is simpler and because it is more known, as the same Aristotle writes (*1. Phys. T.39*). The third, from (*1. Post. c.20. T.41*), is into ostensive and leading to the impossible, which Scotus mentions (*Quol.2. §. de 2. H.*) and I explain in the Epitome (*l.4. q.1. a.11*). Only this much needs to be noted here: the first is a true demonstration; but the second scarcely merits the name of demonstration, rather that of refutation, as Aristotle wishes (*ubisupra T.40*); and it is commonly called an argument ad hominem. The reason is that the ostensive proceeds from prior things and directly draws its conclusion, while the one leading to the impossible proceeds obliquely and indirectly — not from truth to truth, but from the falsity of the opposite to the falsity of the opposite, since it demonstrates the falsity of a true proposition from the falsity of the proposed conclusion, as was illustrated by example in the passage cited. The fourth, from the Doctor (*1. Post. q.55. §. Adq.*), is into the demonstration propter quid and the demonstration quia, one of which Aristotle calls to dioti and the other to hoti (*cit. c.10*). Since this division is the principal one, it must be diligently examined by me in the present place. Two differences between the two, assigned by Aristotle (*c.4 of the same book*),

intervene. The first: the demonstration propter quid always proceeds through the proximate cause, while the demonstration quia sometimes proceeds through the remote cause. The second: the quia demonstration proceeds through the effect, the propter quid demonstration by no means. From these I gather, first, that a quia demonstration through a convertible effect is possible, as is clear in these two: every non-twinkling thing is near; the planets do not twinkle; therefore the planets are near. And: every thing whose light increases spherically is spherical; the moon is something whose light increases spherically; therefore the moon is spherical. I gather, second, that there can be a negative demonstration through an effect not reciprocal with the cause — more common than the cause — and a positive demonstration is had, as: every triangle has three angles; therefore every triangle is a figure. I gather, third, that there can also be a quia demonstration through a remote cause, as: every breather is an animal; no stone is an animal; therefore no stone breathes.

Note second that, given a double cause — proximate and remote — a double effect must be conceded, proximate and remote, because cause and effect are correlatives whose simultaneous existence in nature the Stagirite records in the chapter on relatives. Between a proximate cause and its proximate effect there is a necessary and essential connection, such that when the proximate cause is posited its effect is necessarily posited, and conversely when the proximate cause is removed its proximate effect is necessarily removed — as if form is taken from matter, its information is removed; and if the soul is separated from the body, its animation and what essentially depends on it must be removed. But this indissoluble link is not always found between a remote cause and its effect, because it is generally wider. Therefore when it is posited, it is not necessary that its effect be posited. Hence Aristotle prescribes that it should be formed not as affirmative but as negative, in Camestres, which is the mode of the second figure, as is clear from the example I adduced at the end of the first note, in which the remote cause of breathing — namely animal — is adduced; this is not the precise cause, but to have lungs, as the Doctor explains (*16. univ. §. Ad 3. in solutione quinti*): for a fish is an animal and yet does not breathe, because it lacks lungs, as the Doctor touches on (*2. d. 34. ante §. Ideò merito*).

Note third that the propter quid demonstration can be constructed through an extrinsic cause, as: as often as the earth is interposed between the sun and the moon, the moon is eclipsed; when the sun and moon are at the head or tail of the dragon, the earth is interposed between the sun and the moon; therefore at that time the moon is eclipsed. Or through an intrinsic cause, which happens when its middle term is the definition of the subject, as: every rational being is risible; every man is rational; therefore every man is risible. Now since demonstration is effected through the four kinds of causes, as Scotus proves (*q. 57*), of which two are extrinsic — efficient and final — and the others intrinsic — material and formal — the most powerful demonstration, which Aristotle and Scotus call demonstration simply speaking, is that which is had through the

formal, proximate, and immediate cause. The remaining demonstrations are less noble and less valuable, because they are lacking in some of the conditions necessary for perfect demonstration, though they possess others by reason of which they are called demonstrations — not absolutely, but with an addition — or secondary demonstrations of a second kind, as Zabarella observes (*l. de speciebus demonstrationis c.1*). Thus demonstration taken universally can be divided into demonstration propter quid and demonstration quia; demonstration propter quid into primary and secondary — the former being constituted through the proximate and immediate cause, the latter through another cause of the other kinds of causes we described. The demonstration quia is further divided into demonstration from the effect and demonstration through the remote cause; and again it can be subdivided into demonstration from an immediate effect and from a remote effect.

Assertion. There are two species of demonstration: propter quid and quia, taken in the manner explained above. So Scotus (*quol. cit. and q. §. post §. ad q. post*) after Aristotle (*1. Post. c.4. T.10*), and Zabarella does not doubt that this is the truest position (*b.1. praalleg.*). Proof, first: every necessary truth not known from its terms, having a necessary connection with another necessary truth, can be demonstrated in only two ways. Therefore only a twofold species of demonstration is established. The antecedent is proved: for either it is demonstrated a priori, that is, from the cause, and the demonstration propter quid is had; or it is demonstrated a posteriori, that is, from the effect, and there is demonstration quia. Therefore, since no other necessary connection of things remains beyond these two, it is rightly and duly inferred that there are only two species of demonstration. Second: there is only a twofold science, from (*1. Post. T.42*) and (*2. eiusdem operis T.25*). Therefore there is also only a twofold instrument of knowing, or twofold demonstration. The antecedent is at hand: for either a thing is known through the cause, and propter quid science is had; or it is known through the effect, and quia science arises. The consequence holds because the species of demonstration seem to be enumerated according to the species of science, since science proceeds from demonstration as an effect from its cause. I add that nearly every division is twofold or is to be reduced to a twofold one, as I declared from the Doctor (*1.2. q. de differentia*).

You will object, first, that a thing can be known not only by quia or propter quid science, but also by quia and propter quid science simultaneously. Therefore, according to this triple science, a triple species of demonstration must be enumerated. The antecedent is read (*2. Post. T.39*) and expressly explained there by Zabarella. I reply that it is per accidens for the same thing to be known simultaneously by quia and propter quid demonstration. For no peculiar third science is generated thereby, by reason of which a third species of demonstration distinct from the two named would have to be admitted, since no third necessary and essential connection of things remains beyond the connections of cause to effect and effect to cause, as was established above.

You will object, second, that a third mode of knowing a thing certainly and evidently exists — proceeding from effect to effect and from equal to equal. Therefore a third species of demonstration invented by Themistius must be admitted. The antecedent is urged: when two effects necessarily depend on one and the same cause and are reciprocated with that cause, one can be demonstrated through the other, proceeding from equal to equal — as from putrid fever two accidents proceed, namely irregularity of pulse and a certain heat residing in the sick person, as its two effects convertible with the fever itself; one of them is not the cause of the other, yet they are necessarily conjoined, and so an argument or demonstration from effect to effect can be formed: whoever has such heat in himself has irregularity of pulse; in Peter, for example, there is said heat; therefore also irregularity of pulse. I deny the antecedent; and to its proof I say that between these effects there is no per se necessary link except per accidens and by reason of a third thing, since one does not enter into the definition of the other, nor is one the cause or property of the other. Therefore such an argumentation is alien to demonstration, which requires a per se necessary link of one extreme with the other; and consequently such an argumentation is not to be ascribed among demonstrations.

You will object, third, that from remote causes sometimes there proceed effects convertible with them. Therefore from them an affirmative demonstration can be constructed in the first figure, which seems to have been asserted with Aristotle above. Granting the antecedent, I deny the consequence. The reason is that what happens rarely is per accidens and is not per se considered by science. But Aristotle, having regard to what is necessary and perpetual, asserts that the demonstration through a remote cause occurs in Camestres, where the major is a universal affirmative, and the minor and conclusion are universal negatives.

You will object, fourth, that certain demonstrations exist that are neither through cause nor through effect — for example: every man is an animal; John is a man; therefore John is an animal. Therefore the division of demonstration adduced above is deficient and incomplete. The antecedent is conceded, since animal is neither the cause of man nor its effect. It is confirmed: when a definition is demonstrated by the defined, or conversely the defined by the definition, there is no demonstration belonging to either of the two just assigned. Therefore the aforesaid division is insufficient. Some, pressed by this argument, are convinced and concede that the division is inadequate and insufficient. But I am not constrained by this, since such argumentations hold through the intrinsic locus from the universal whole to the subjective parts, as I explained in the Epitome (*l.3. q.3. art.3*). Especially because these proceed from essential principles, which stand as causes taken broadly — especially in logical terms, where the genus stands as matter and the difference as form to constituting the whole which is the species composed from them, as I said in the second book. And therefore they fall under the aforesaid division.

Article III. Whether Demonstration Is from True Premises.

Five conditions are enumerated in the material definition of demonstration adduced in the preceding article, and must now be examined individually; among them the truth of the premises holds the foremost place. For demonstration must consist of true things — which is the common assertion of Aristotle in the present place, Scotus (*ibid.* q.1), and others. It is proved, first, from the fact that an effect leads us to cognition of its cause, as philosophers teach with Aristotle (*1. Met. c.2*); but the effect of demonstration is true — namely science, whose end, especially if it is speculative science, is the contemplation of truth, from (*6. Met. c.1*). Therefore also its causes, which are the premises, must be true. Second, it is a commonly received principle among dialecticians that the conclusion follows the weaker part: if one of the premises is negative, the conclusion will be negative; if particular, the conclusion will likewise be particular; and consequently if any premise is false, the conclusion too will turn out false. But science, which is placed in the conclusion, can be neither false nor of a false thing, as is clear from its description in (*1. Post. c.2*). For this reason the philosopher adds there — according to Philoponus — that there is no science of the false. Therefore demonstration proceeds from what is true. Now a greater difficulty arises as to whether the premises are truer than the conclusion. For on the side of denial stand Hurtado (*disp.11. Sect.2*), Arriaga (*disp.1.3. sect.3*), and Fuentes (*q.19. diff.1. art.2*), while the affirmative part is commonly defended by others cited by the aforesaid more recent authors. This dispute, I judge, must be settled by distinction — namely, the premises taken fundamentally are truer than the conclusion, but not taken formally — as I made fully clear in the fourth book (*q.4. art.2*).

Assertion. Demonstration proceeds from premises that are truer than the conclusion fundamentally speaking, but not taken formally. This assertion in both its parts is proved by the advocates of each opinion recounted above; and indeed: the first part is urged, first, from Aristotle (*both here and also 4. Met. T.18. c.4*) and Scotus (*ibid. and 2. dist.26. q.vn. §. Ad 1. tertia via paulò post AA.*) who affirm that one thing can be truer or falser than another. It is proved, second, that truth is the conformity of the intellect with the object; but a proposition about an object is truer than another — as it is truer to say man is a rational animal than that man is white. Therefore premises composed of terms about truer objects are truer than the conclusion deduced from them. Third: it is falser to say three and two are one thousand than to say three and two are six; and it is falser to say man is a stone than that he is a dog. Therefore it is truer to say three and two are five than to say Peter is writing or running. The consequence holds by that axiom: by reason of which something is such, that thing is more so — and this concords with our assertion together with the conditions explained above, as is evident to one reasoning through them. And so I briefly form the argument: what is the univocal and total cause susceptible of more and less is more perfect than its univocal effect; but premises are of this kind, as is clear from what has

been said. Therefore, etc. Second: absolutely speaking, what depends on another is not equally noble, known, and perfect as that on which it depends, as the Doctor expressly declares (*q.13*) and explains and limits (*4. dist.49. q.4. §. Iuxta hoc infra. N.*); but the conclusion depends on the premises as an effect on its cause. Therefore the premises surpass it in certitude, evidence, and perfection. Third: the closer something is to what is most known and most evident, the more known and evident it is; but principles are closer to the first principles — that is, self-evident and most universal principles. Add that a univocal cause is nobler than its effect, as the Doctor asserts throughout, notably (*2. dist.26. q.vn. §. Hic dicitur ante A.*); the reason being that it contains it virtually, which also denotes greater perfection — as is clear of God who contains creatures virtually, as I pursue at length in the treatise on Creation (*disp.3*). I conclude, therefore, that premises surpass the conclusion in certitude, evidence, and perfection.

The second part is in accordance with Scotus (*1. Post. q.13. ad finem*) and the Scotists cited (*l. 4. q.4. art.2. assert.2*), who teach that truth formally is a relation; and hence I derive the proof of this part as follows: a relation formally taken does not admit of more and less, whether in the concrete — as one father is not more a father than another father — or in the abstract — as one paternity is not more a paternity than another paternity. But truth formally is a relation, as I showed in the place now cited. Therefore the truth of the premises formally is not greater or lesser than the truth of the conclusion caused and collected from them. Furthermore, truth is a commensuration and adequation of the act of the intellect with the object; but this adequation consists in something indivisible. For if the object is adequated to the act of the intellect, no other object can be more adequated to it — otherwise it would not be adequated to it, which is contrary to the supposition. And further, the indivisible does not admit of more and less; since therefore truth is indivisible, it is formally equal in premises and in conclusion. This argument does not seem to favor those who do not distinguish truth from the act of the intellect, whom I mentioned in the place recently cited; for since through them the act of the intellect is a quality to which belongs admitting of more and less, this property does not seem to be deniable of truth of this kind.

You will object, first, against the first assertion, that sometimes truth follows from falsity, as is read in (*l. consequentiarum Joannis Morissiis reg.1*) and is asserted by the Doctor (*q.15. §. Ad quest.*) and is derived from Aristotle (*1. Prior.*) as cited by Lychetus (*1. dist.2. q.2. §. Secundo principaliter*). Therefore it is not necessary that demonstration be constructed from true things. The antecedent is clear in this syllogism: every animal is black; a crow is an animal; therefore a crow is black. Here from a false major and a true minor a true conclusion is gathered. It is confirmed, first, that Aristotle (*8. Phys. T.45*) from motion — which he falsely established as eternal — infers that the first Mover is eternal, which is true. It is confirmed, second, that in the demonstration leading to the impossible, one of the premises is always false, as the Doctor argues in the place cited above;

therefore not every demonstration is composed from true things. I distinguish the antecedent: *per se* — I deny; *per accidens* — I concede. But what is *per accidens* does not fall under science, as I was noting above; and so Scotus, Maior, and others who accept the said canon are to be interpreted. To the first confirmation, the same distinction and interpretation is to be applied; especially because, according to truth and the Catholic faith, God is not a necessary but a free first mover — as he clearly implied by creating the world in time, as I showed at length in the treatise on Creation (*disp.1*). To the second confirmation, it can be said that the assertion of the assertion is to be taken of ostensive demonstration, not of that leading to the impossible, whose reason I adduced in the preceding article, first note, and the Doctor implies (*ante §. Contrà*). Or say, with the same Doctor in the same place, that such a demonstration is made from true things as regards the third process, which is from the destruction of the hypothesis to showing that the principal proposition is true.

You will object, second, against the same assertion, that demonstrations are made concerning the void, the infinite, and other things that are beings or false beings. Therefore demonstration is not always composed from true things. The consequence holds because truth is a property of being; therefore non-being is not true, since opposites do not enjoy the same properties. The antecedent is urged: those things are knowable in some way, since they are considered by Physics, which is a real science; especially because concerning non-being, what is opposed to being can be known. And so of it and other things named above a scientific demonstration can be made; and consequently demonstration is not always framed from true things. I reply with the Doctor in that place (§. *Ad primam*): of those and similar things there is a negative demonstration and science, not a positive one, which is always from true things, and in this sense we speak with Aristotle in the present place.

You will object, third, against the second part of the assertion, that one of the properties of relatives enumerated by Aristotle in the chapter on relatives is to admit of more and less. Therefore, since truth from what was asserted is a relation, it undoubtedly follows that this property agrees with it; and thus the premises can be truer than the conclusion. It is confirmed: where there is greater union and greater conformity of extremes in some third thing, there is greater truth, as may be collected from the Doctor in the first place cited; but this happens in some premises. Therefore the premises are truer than the conclusion. I reply that this property is attributed to a relation not formally but fundamentally — that is, by reason of the foundation in which it is grounded — for example, because whiteness and blackness admit of more and less, the relations of similarity and dissimilarity founded in them are said to admit of more and less. The same is affirmed of contrariety, as the Conimbricenses note (*in comment. c.7*) after Scotus (*q.26. praedicam. §. De prima proprietate*) and Boethius. To the confirmation, the same reply and interpretation just adduced applies.

Article IV. Whether Demonstration Is from Primary and Immediate Things.

The second condition of demonstration delivered by Aristotle is that it be from primary and immediate things, which some consider twofold, as the Doctor implies (*1. Post. q.11. §. Ad 1. rationem*); while others commonly, notably Zabarella (*in com. T.9*), Arriaga, and Mastrius and Bellutus (*part.2. Inst. Tract.1. c.4. and disp.13. q.3. art.1*), see it as only one condition — and the Doctor in the place now cited does not demur, though he places some difference between them, drawn from a diverse property. For this reason neither ought to be judged superfluous or deficient, as the notion and signification of each term plainly demonstrate, and the Doctor indicates not obscurely (*both here and in q.1. art.1*). Whether therefore these differ or coincide, they admit without doubt this exposition consonant with the said Doctor. Demonstration is from primary things, that is, principles — the Doctor's interpretation (*cit. q.11. §. Ad quaest.*). From immediate things: supply finally, as the Doctor explains (*ibid. in fine loci cit.*). For although sometimes demonstration is made from mediate things, nevertheless in the end it is resolved into the immediate. And so demonstration is composed of principles, which can be indemonstrable and common — indeed most common, mentioned by the Stagirite (*c.8 of this book*) — and demonstrable and proper, which the same philosopher cites (*ibid. and 4. Met. c.3*); and all of these are found in the sciences, both subalternate and non-subalternate. For in the latter — especially in Metaphysics — the most common and indemonstrable principles are found; in the former, demonstrable principles that, though not proved by the subalternated, are well shown by the subalternating sciences, as I shall make fully clear in the question on science. Furthermore, I observe that a proposition is called immediate and indemonstrable because it lacks a middle term; and this can happen in three ways. First, because it lacks a middle term both a priori and a posteriori — such as the absolutely first principles, which are altogether indemonstrable — as: it is impossible to affirm and deny the same thing of the same, and those which the philosopher considers in (*4. Met. c.3*) and onwards. Second, because it lacks a middle term a priori but not a posteriori — as: man is a rational animal — this proposition has no middle term through which it is demonstrated a priori, yet it can be demonstrated a posteriori through its property and quasi-effect: every risible thing is rational; every man is risible; therefore every man is rational. Third, because it is destitute of a middle term a posteriori, although it has one a priori — as is the case with the proposition just cited, which has a cause through which it is demonstrated a priori, but not a posteriori. What is said of necessary propositions must likewise be asserted of contingent ones.

Assertion. Demonstration is composed of primary and immediate things either actually or virtually — that is, finally. So Scotus (*in q. cit.*) in both its parts, followed by Raconius (*disp.1. art.4*), Hurtado (*disp.11. sect.5*), and Arriaga (*disp.16. sect.6*). The first part is proved: some demonstrations are made from

indemonstrable premises, both a priori and a posteriori, as I noted above and illustrated by example. Therefore demonstrations of this kind, which are composed from those, consist of primary and immediate things actually. The second part is proved: in effects and per se causes there is no proceeding to infinity, as is clear in the Physics in the book on causes; otherwise nothing would be known, as Scotus infers (*ubisupra* §. *Adq.*). But some propositions are demonstrable through others, as when propositions and argumentations are formed from properties ordered among themselves, one being shown through another — as the weepable through the risible, the risible through the admiring, and the admiring through the discursive and rational — in which one finally arrives at an immediate and indemonstrable principle. Therefore finally demonstration consists of primary and immediate things.

You will object, first, that every demonstration is from immediate things; therefore no demonstration is made from mediate things, since the immediate and the mediate seem to be opposed; and that no demonstration is composed from mediate things conflicts with Aristotle (*both here and in 1. Top. 1.*) and with reason, because since some principles are immediate and some mediate — as is clear from the foregoing — it consequently follows that demonstrations made from mediate principles are mediate. I distinguish the antecedent: every demonstration is made from immediate things proximately or remotely, actually or virtually — I concede; proximately and actually always — I deny; for as the instance proves, some demonstrations actually and proximately consist of mediate things, which are finally resolved into the immediate, as the Doctor writes at the close of the question cited.

You will object, second, that if every demonstration is composed of primary and immediate principles, then every demonstration is a priori and from the cause, and none is a posteriori and from the effect — which contradicts the Stagirite (*1. and 2. of this work*) and the common doctrine of philosophers. I reply with Scotus cited, through distinction of the consequent: concerning demonstration simply speaking, which Aristotle defines — I concede; concerning demonstration in a qualified sense, such as the demonstration a posteriori and from the effect — I deny.

Article V. Whether Demonstration Is from Prior and More Known Things.

Concerning the first part of the proposed title, the dialecticians do not contend, since it is more than clear that propositional premises precede the conclusion — which is understood and proved in the first question of this book (*a.9*); and somewhat more will be touched on below in the first note. Concerning the second part of this article, however, I see that not all are agreed — especially the more recent authors, who, wishing to add something to what was discovered by the ancients and not to enter into their positions, endeavor to introduce new things into the schools. They defend that principles neither in certitude, nor in

evidence, nor in perfection surpass the conclusion; among these are Arriaga (*disp.16. Sect.4. subsectione 2*), who warns the Reader in the preface to his philosophical course that novelty of opinions should not be feared; and Hurtado (*disp.11. sect.3*) and others whose names Hurtado (*ibid.*) and Ruuvius (*c.2. q.5*) retain. That certain lovers of novelty and students did the same thing in other matters in their time, Auriol reports (*in Prol. fol.57. art.2*), who — following the reasoning of their positions and departing from Aristotelian and common doctrine, especially Ockham and his disciples — are not rarely imitated by the aforementioned more recent authors. The common body of philosophers, however, is with Aristotle (*1. Post. c.2*), Scotus (*q.11. §. Adq. and q.13. §. Adq. dicitur*), the Inseparable Scotists (*disp.13. q.3. a.2*), Fuentes (*q.19. diff.1. q.3*), Raconius (*disp.1. q.3. a.2. sect.2*), Conimbricenses (*a.5. q.2. c.2*), and others who teach that the premises are more known, more evident, and more perfect than the conclusion, whether taken separately or together.

Note first, from the Doctor (*q.11. §. Ad 1. rationem*), that primary is used in two ways: one way in itself and absolutely — that is, by negation of the prior — thus the categories are called first genera because no other genus is placed above these supreme genera; the other way by comparison to the posterior — that is, the first to the second — and in this way premises are called prior in order to the conclusion, which is posterior to them, just as an effect is posterior to its cause. This same acceptation is admitted by the name firstborn, as I noted in the treatise on the Triune God (*disp.1. q.7*). Furthermore, from Aristotle cited (*T.5. c.2*) and Scotus (*q.10. §. Ad primam*), prior and more known are said in two ways: prior and more known by nature — which is what is most distant from the senses, such as the universal; and prior and more known to us — which is what is closest to the senses, such as the singular. Sometimes what is more known by nature is also more known to us, as are many things in the mathematical disciplines — for example, every whole is greater than its part; likewise, a right angle is greater than an acute angle. Now the *propter quid* demonstration proceeds from prior and more known by nature; the *quia* demonstration does not.

Note second that science caused by demonstration includes principally two things: certitude and evidence, which stand to one another as superior and inferior, or as more common and less common. For every evidence includes certitude, but not vice versa. Faith, for example, is indeed certain, yet not evident. Certitude, moreover, is described as the firm adherence of the intellect to some object — as I am certain that God is triune and one, because I firmly adhere to the page attesting this to me. Evidence, on the other hand, is a clear and plain knowledge of the object. All of this is drawn from the Doctor (*q.3. prol. 3. d.24. q.vii. §. Ad q. infrà D.*), who, adducing the conditions of science, places certitude and evidence as the foremost, saying that science is certain and evident cognition. Perfection, on the other hand, can be called the integrity of a thing, which is convertible with goodness and beauty taken transcendently, as

the Sacred Interpreters signify (*Gen.1.*); and perfect is that to which nothing is lacking, as Scotus, Gadius (*Quol.18. fol.182*), Pelbartus (*Tomo 1. verbo perfectio*), and Vorrilong (*1. d.36*) hold together, which must be diligently investigated elsewhere.

Note third that the axiom, by reason of which something is such that thing is more so — of which Aristotle makes use here (*T.5. c.2*) and mentions (*4. Met. T.4*) — to prove that premises are more known and more evident than the conclusion, is restricted by many to numerous conditions, of which Maior (*1. Post. fol.69. §. Nota and §. Epilogando*) enumerates five, and concludes that it holds only in the genus of efficient and final cause. Tataretus (*ibid. q.2. scibili 4*), for its explanation and verification, adduces three conditions, of which two are placed by Aristotle in the Metaphysics cited, and a third is added by others. The first is that what is predicated of cause and effect formally belongs to each; thus these instances do not hold: the air is hot because of the sun, therefore the sun is more hot; and Peter is drunk because of wine, therefore wine is more drunk — because neither heat formally belongs to the sun, nor drunkenness to wine. The second, that what is said of cause and effect admits of more and less; thus it is not rightly deduced that Francis is a man because of his father, therefore his father is more a man. The third, that one with respect to the other, between which the comparison is made, is the total and adequate cause — for want of which it does not follow that the natural composite is perfect because of form, therefore form is more perfect than the composite, because form is the partial cause thereof, being itself less perfect than the whole which includes it, as Scotus affirms (*1. d.3. q.2. §. Loquendo. Sub M.*). The Doctor touches on these modulations (*1. Perih. §. Ad partem oppositam*) and (*1. Post. q.12. q. Adq. and §. Ad primam*), saying that the aforesaid maxim is to be taken of an efficient, univocal, per se essential, and total cause.

Assertion. The premises of demonstration are more known, more evident, and more perfect than the conclusion. So Scotus in the places cited before the first note, together with Aristotle in the passage mentioned. Proof, first: that which is the cause of another is more known, more evident, and more perfect than it in itself, as I asserted (*l.5. Phys. q.1. a.5*). For it seems to belong to the notion of a cause that whatever is present in the effect in a more excellent and eminent manner is found in the cause, since the cause virtually contains its effect. But premises are, as I have shown elsewhere, the causes of the conclusion. Therefore, the conclusion being known, certain, evident, and perfect, the premises are more known, more certain, more evident, and more perfect. The consequence is clear by the rule assigned above — by reason of which something is such that thing is more so — which fittingly concords with our assertion together with the conditions explained above, as is clear to one who reasons through them. And so I briefly form the argument: what is the univocal and total cause admitting more and less is more perfect than its univocal effect; but the premises are of this kind, as is clear from what has been said. Therefore,

etc. Second: absolutely, what depends on another is not equally noble, known, and perfect as that on which it depends, as the Doctor expressly declares (*q.13*) and explains and limits (*4. dist.49. q.4. §. Iuxta hoc infrà. N.*); but the conclusion depends on the premises as an effect on its cause. Therefore these surpass it in certitude, evidence, and perfection. Third: the closer something is to what is most known and most evident, the more known and evident it is; but principles are closer to the first principles — that is, self-evident and most universal principles. Add that a univocal cause is nobler than its effect, as the Doctor asserts throughout, notably (*2. dist.26. q.vii. §. Hic dicitur ante A.*); the reason being that it virtually contains it, which also denotes greater perfection — as is clear of God who contains creatures virtually, as I pursue at length in the treatise on Creation (*disp.3*). I conclude, therefore, that premises surpass the conclusion in certitude, evidence, and perfection.

You will object, first, that Aristotle (*1. Post. c.2*) asserts that it is not necessary to assent to all principles more than to the conclusion, but to all or to some. Therefore according to Aristotle principles are not always more certain, known, and evident than the conclusion. It is confirmed: Scotus in the places cited adds that the axiom which the philosopher uses to urge that principles surpass the conclusion in certitude and evidence is to be interpreted of a univocal cause per se, whose effect is equally noble and excellent as the cause itself. Therefore the conclusion, in terms of certitude and evidence, is not inferior to the principles. Zabarella replies from Averroes that the philosopher spoke disjunctively, not because he thinks both options are true, as the Greeks explain, but because he did not wish to discuss this difficulty in that place. One can also say that the reason is equal for all principles; for both the major and the minor are causes of the conclusion, and therefore each ought to be more known and evident than the conclusion. To the confirmation, Scotus satisfies it (*q.12. §. Ad primam*): the principles are more known than the conclusion insofar as cognition, or science, is the apprehension of the truth of necessary things — in which way principles are the univocal cause of the conclusion; but if the discussion concerns cognition and science properly speaking, which is acquired through the cause, principles are the equivocal causes of the conclusion, because the conclusion is had through its cause, while principles are not.

You will object, second, that we assent to the conclusion in nearly the same way and for the same reason as to the premises. Therefore the conclusion is equally known and evident as the premises. The antecedent is proved: by the same union by which the extremes are connected with the middle term they are joined with each other; but things that are the same as a third thing are the same as each other, as the common saying of dialecticians expounded and confirmed by the Doctor (*1. Prior. q.9*) has it. Therefore, since the extremes in the premises have the same union as in the conclusion — as is clear in this demonstration: every rational is risible; every man is rational; therefore every man is risible — it is clearly deduced that the premises are not more certain and evident than it,

especially since they share the same object and formal motive. I deny the antecedent; and to its proof I say that the union of the extremes with the middle term is formally or virtually immediate and independent; while the union of the extremes with each other, which is had in the conclusion, is mediate and dependent. Therefore nothing is concluded by the argument. To what is further urged, I say it has already been dissolved in (*q.1. art.7 of this book*), where it was proved that assent to premises differs from assent to the conclusion, and that their formal objects are distinct from that of the conclusion, as Scotus affirms (*3. dist.23. q.vn. §. Secundo sub D.*) and (*dist.28. q.vn. §. Ad 1. infra G.*).

You will object, third, that what is cognized through the cause is more known than what is not cognized through the cause, as is clear of universal and particular demonstration. For the former according to Aristotle is more known than the latter, because it is cognized through the cause; but the latter is not. But the conclusion is cognized through the cause; while principles are known from the cognition of terms alone. Therefore, etc. I reply with Scotus that the major holds when both extremes are cognizable through the cause — which is not the case with first principles, which become known through the sole knowledge of terms, as is assumed in the proof of the minor.

You will object, fourth, that the more noble is not ordered to the less noble, as is evident in this universe of things, and is indicated by St. Paul (*1. Corint.3*) in these words: all things are yours, you are Christ's, and Christ is God's. The reason is that the end is nobler than those things that are for the end, as is established from the book on causes in the question on the final cause; but principles are ordered to the conclusion. Therefore they are not nobler or more certain than it. I reply: granting the major, I distinguish the minor: as means to an end — I deny; as causes to their effect — I concede. For principles virtually contain the conclusion. Hence Scotus adds near the end of (*q.13*): the principle, insofar as the science of the conclusion is contained in it in universal and confused manner, is ordered to perfect cognition of the universal and of the particular — in which way the imperfect is ordered to the perfect.

You will object, fifth, that more causes of equal force and nobility applied to produce an effect bring about an effect more noble and excellent than fewer causes of the same genus and kind. But more equally noble causes flow into the conclusion than into the principles. Therefore the conclusion is more perfect and noble than they. The major is obvious. The minor is shown: to bring forth the cognition of principles, only the object and the light of the intellect concur; but to cause the conclusion, besides the object and the light of the intellect, the premises themselves cooperate. I reply that the major is true of an effect of greater nobility that is capable; but false of an effect that is incapable of greater perfection, such as the conclusion, which can be affected with neither as great nor greater nobility than that which the principles possess, since it is their equivocal effect.

You will object, sixth, that from two premises of faith there follows a conclusion of faith, which is equally certain as the very premises from which it is drawn. Therefore it cannot be denied that the conclusion is equally certain as its principles. All the more so because from one natural premise and another premise of faith there is collected a conclusion of faith, which is more certain than the natural premise, as is seen in this syllogism: every man is weepable; Christ is a man; therefore Christ is weepable. And so the conclusion can be more certain than the premises. I reply that our assertion is to be taken of premises that have a formal object and assent distinct from the object and assent of the conclusion — as premises of faith and a conclusion deduced from them do not, for they share the same object, the same assent, and the same motive, as Scotus affirms (*3. dist.23. q.vn. §. Adquest. D.*). But if you wish the same doctrine to hold universally of natural and revealed syllogisms, say that the conclusion collected from principles of faith is not equally certain as its principles, since those immediately rest on divine testimony, while this belongs mediately to the theological habit — concerning which there is abundant treatment in the first treatise of our *Summa Theologica*. Whatever Fuentes says (*q.19. diff.1. art.3. ad 4. 5. objectionem*). To the further point urged, the same must be said. For according to that dialectician's maxim, the conclusion always follows the weaker part; and therefore, whether both premises are of faith or only one of the premises, the conclusion is always less certain — as Ruuvius also infers (*c.2. q.5. primi Post.*).

You will object, seventh, that if our assertion is true, it is so especially because of that axiom delivered by the philosopher cited and restricted and confirmed by the three modifications; but this is seen to be false in many cases — most importantly in this: things are hot because of fire; therefore fire is more hot. The antecedent is true and the consequent false. But iron hurts the one touching it more than fire does; therefore iron is hotter. This comes from nothing other than the greater heat present in the iron. Scotus replies (*q.12*) that this is per accidens: for although iron heats more than fire, this does not arise from greater heat inhering in iron, but from the density of matter in which the force of heat is united — and therefore more active — according to that well-known saying: power united is stronger than itself dispersed, as the Doctor implies (*2. dist.42. q.4. §. Respondeo G.*) and Maior sets forth (*fol.69. colum.4*). The remaining condition of demonstration is that it be from causes, which I examined in (*q.1. art.8*). Since demonstration is the perfect mode of knowing, it must consist of causes, because science is cognition of a thing through its cause from (*1. Post. T.1*), whether the cause be actual or virtual, as the philosopher shows (*2. Caeli T.13*): for having proved there that the east is the right side or principle of motion, he objects to himself that the motion of the heavens never began, because in his opinion the world is eternal; and he replies that if motion had begun, it would have taken its beginning from the east. Hence it is clear that in that place Aristotle uses a virtual cause for demonstrating — described as that which does not truly produce an effect, yet if the effect were to be produced, it

would proceed from none other than that which is assigned — as in God incomprehensibility would proceed from infinity and eternity from immutability, as the paired Scotists affirm (*2. part. Inst. Tract.1. c.4*).

Article VI. Whether the Premises of Demonstration Are from Necessary Things and from All.

Some more recent authors, among whom are numbered Hurtado (*disp.9. sect.6*) and in part Arriaga (*disp.16. sect.7*) and Conimbricenses (*c.7. q.1. art.3. ad 2*) — but only with respect to singulars — consistently affirm that demonstration can be made from contingent, singular, and corruptible things. Against them I oppose nearly the entire school of philosophers, first Aristotle (*1. Post. c.4.8*) and elsewhere, Scotus (*q.14*), Maior (*ibidem fol.70. §. Ad 2*), Fuentes (*q.19. diff.1. art.7*), and others who teach that demonstration is composed of necessary, universal, and eternal things.

Note first that Aristotle (*citat. c.4. T.44*) puts forward other conditions of demonstration — namely that demonstration consists of necessary things, proper things, from all, per se, and of universal predicate — which he does not adduce or mention in (*c.2 of the same book*) where he defines demonstration and examines its principal conditions. Zabarella gives the reason (*l. de speciebus demonstrationis c.3*): because those conditions are not distinct from these, but these implicitly contain those, which in (*c.4 alleg.*) he teaches explicitly. For principles being true, immediate, prior, and more known cannot be so unless they are proper, from all, per se, and according to what itself — as will become more clear from what will be said. Hence three grades of necessity required for demonstration are noted: the first is that the demonstration be from all; the second that it be per se; and the third that it be of the predicate convertible with the subject. These must be explained by us individually — the first in the present place, and the rest in the two following articles.

Note second that syncategoremata or universal signs — namely all or none — appended to any subject render a proposition universal, as I noted in the Epitome (*l.2. q.2. art.3*). When therefore Aristotle says that demonstration, or the proposition of a demonstration, as Zabarella explains (*l.1. de propositionibus necessariis in fine c.2. 1. Post. in comm. c.4*), must be from all — that is, of a universal subject, by reason of which it is called universal. Now since universality can be sought in two respects — namely with respect to the subject of which its predicate is universally stated, and with respect to the perpetuity of time — there accordingly arises a twofold predication: from all in the prior sense, and from all in the posterior sense. The former is when the predicate is said of every subject, with no account taken of the universality of time — as if at present all men were white, this would be from all in the prior sense: every man is white. But if the predicate is applied and stated of the subject not only at every subject but also at every time, the proposition from all in the posterior sense is had — as every man is an animal. The former is called from all in the prior sense because

in the Prior Books only the syllogistic form is attended to without the perpetuity of time. The latter is called from all in the posterior sense because the universality and perpetuity of time is attended to in it. Wherefore this first grade of necessity requires two conditions: one which is the universality and perpetuity of the subject; the other which is the perpetual link between subject and predicate, which I treated in the fourth book.

First Assertion. The premises of demonstration must be necessary. Scotus holds this expressly with Aristotle cited at the beginning of the article, and (*1. dist.3. q.4. §. Ad 2. artic.*). Proof, first: what are immediate or mediate principles are necessary; but the premises of demonstration are immediate or mediate principles. Therefore the premises of demonstration are necessary. The major is clearer than the midday sun; and indeed that principles are necessary, especially immediate ones, is read (*2. Met. c.1*): the first principles are known to all like the doorway in a house, because the doorway is hidden from no one, as the Doctor cites in the first place just cited (*§. Ista rationes*), and explains in the Metaphysics in the passage mentioned, where Anthony Andrews, Orbellus, and others comment. Mediate ones are also seen to be necessary because they derive their necessity from the first and immediate ones. The minor is sufficiently clear from the preceding articles and the material definition of demonstration makes it most evident. Second, from the same places cited (*§. De secundis E.*): a natural and necessary effect has a natural and necessary cause, just as a free and contingent effect has a free and contingent cause. But the effect of the premises of demonstration is necessary — namely the conclusion, which possesses the necessity of both the syllogistic form and the matter, as is clear in the prologue (*q.4*). And in this the demonstrative syllogism differs from the topical, because the latter participates only in the syllogistic form, while the former enjoys both. Therefore demonstration is composed of necessary principles.

Second Assertion. Demonstration requires premises from all in the posterior sense. So Scotus with Aristotle in the place cited above, and this follows from the preceding assertion. For that is a proposition from all in the posterior sense whose predicate is stated of every subjective part of its subject, and between both its extremes there is a perpetual link, as I declared in the second note. But the premises of demonstration are of this kind, as I proved in the first assertion. Therefore demonstration is composed of premises from all in the posterior sense.

Third Assertion. Demonstration must be composed of universal, incorruptible, and perpetual things. The first part is from Aristotle (*this place, and 2. de anima T.80, 7. Met. T.53*) and frequently elsewhere; and from Scotus (*ibidem in fine q.34. and collatione 26. §. Ad 1. istorum*). Proof, first: demonstration is made from premises from all, as is clear from the preceding assertion; but it cannot be from all unless it is from universal things, as is clear from the first note. Therefore demonstration consists of universal things. Second: science is of the universal,

from (2. *de anima* T.60); hence Plato invented the ideas of things, lest there be no universals about which science is had, as I noted (1.2. q.1. art.3). Again, singulars do not have proper properties distinct from the properties of the common nature, as Conimbricenses concede (c.7. q.1. a.3) after Scotus (2. d.9 q.2. §. *Ad argumenta* X). Therefore demonstration is not constructed from them. The second part is defended by Aristotle (1. *Post.* c.7. T.21) and Scotus (*ibid.* q.14. §. *Ad 1. dicitur*). Proof, first: necessary things are incorruptible and perpetual, as may be deduced from the definition of science delivered by Aristotle (1. *Post.* c.2. T.5); and the reason is that they are indissoluble and inseparable from each other. But demonstration is made from necessary things as I showed in the first assertion. Therefore also from eternal and perpetual things. Second: the conclusion of demonstration is of eternal and incorruptible things, because it is scientific; and science is of incorruptible and eternal things, from the same Aristotle cited above. Therefore the premises must also be incorruptible and eternal, since they are universal; but if one of the premises were singular, the conclusion would likewise be singular and therefore corruptible, as the philosopher argues (*cit.* T.41).

You will object, first, against the first assertion, that Aristotle (1. *Post.* 8.24. T.44) and Scotus (1. d.3. q.4. §. *De secundis* E.) write that every syllogism is made either from necessary propositions or from those that hold for the most part — as rain in winter and heat in summer; but what holds for the most part is contingent. Therefore demonstration does not always consist of necessary premises. It is confirmed, first, that Physics, which is defended by nearly all philosophers as a science, is of mutable things — namely elements and compounds, which undergo perpetual change and vicissitude, as daily experience makes clear. Therefore the demonstrative syllogism is not composed of necessary and immutable things. It is confirmed, second, that for the moon to suffer eclipse rarely happens; but what rarely occurs is contingent; and yet this is had through demonstration. Therefore demonstration can be composed of contingent things. Averroes and other commentators reply that there are two kinds of demonstrations: some are mathematical, which are made from simply necessary things; others are natural, which are composed of those that happen frequently — as the Doctor says of a natural cause and its effect in the place cited. But if through opposition you object that this is hindered, that is, per accidens, which is not worthy of scientific cognition, this is deduced from Aristotle, who (1. *Prior.* c.13. sect.1) says that necessary is what happens for the most part. Or say that Aristotle there speaks disjunctively: namely, every demonstrative syllogism is made from necessary things; a dialectical one from those that happen frequently. Thus every contradiction in the words of the philosopher is removed. To the first confirmation, what is to be said is clear from the first book of Physics (q.1), where it was shown how physical things fall under science by reason of the necessary connection that obtains between them, as Fuentes named above notes. To the second confirmation, I say with Scotus

cited that the demonstration rests on that per se known principle — namely, an opaque body interposed between a luminous body and a transparent one impedes the multiplication of light to such a transparent body; but the earth is such an opaque body interposed between the sun and the moon. Therefore, on account of the premise stated and the cause adduced, it is evidently shown that the moon suffers eclipse. And so as often as such interposition occurs, the moon suffers eclipse, because the cause is natural to producing its natural effect — despite Ruuvius's objection (6.4. q.1).

You will object, second, that from contingent and singular effects produced by God, the existence of God himself is demonstrated — an existence that is necessary — according to that text (*Sap.13*): From the greatness of beauty, the creator of these things can be seen by comparison. And (*Rom.1*): The invisible things of God, understood through the things that are made, are seen — his eternal power and divinity. Therefore from contingent and necessary things a demonstration can be made. It is confirmed: Theology, which is numbered among the sciences, is of contingent and singular things — as of God creating and preserving, augmenting human nature, and other things that are contingent and singular. I reply that those effects can be considered in two ways: in terms of their existence and their free production; or in terms of the essential dependence they have on God. In the first way they do not come into demonstration; in the second way they very much do, because it is impossible for a creature to exist without essentially and necessarily depending on God. Hence Fuentes rightly adds that from the existence of a creature the existence of God is necessarily inferred, on whom the creature necessarily depends. To the confirmation, Scotus responds (*q.4. prot. §. sed aliud. C.*) that Theology is from necessary things as regards the possible — namely that God is creative and receptive of human nature — understanding thus that, as they are taken according to power, they are necessary; although that they be put into effect is not necessary. For it is not necessary that God create, but God is necessarily creative.

You will object, third, that demonstrations are constructed about the sun, the moon, and God, as the Doctor asserts (*1. d.2. q.1. §. Ex his C.*). But these are singulars; therefore demonstration can be made from singulars. The Doctor replies (*collatione 36*) from Aristotle (*1. Met. 55*) that there is science of one thing — as of God or the sun — the science being of God as if there were a thousand Gods, as is clear according to Averroes (*6. Eth.*). Therefore Theology is of God as of something universal, as if there were several Gods — although God is singular. This reply, while it holds for the sun and moon and others of whose species only one individual actually exists, because many individuals of those same species are possible, does not however seem to hold for God, because a plurality of Gods is incompatible with divine nature, as I shall show in the *Metaphysics*. One may say that Aristotle and Averroes — in whose sense Scotus speaks there — were discussing according to the common opinion of those who

admitted a plurality and possibility of gods. Whether there can be science of a singular, eternal, and necessary being, Scotus does not deny; and perhaps Aristotle and Averroes would not have held this — as Faber observes against Vasquez (*1. p. q.1. a.2. c.7*) in the Prologue (*q.3. disp.6. c.1. n.5*).

Article VII. Whether Demonstration Is from Per Se Premises.

The subtle Doctor (*1. Post. from q.15 through q.29*) is very extensive in establishing and declaring the per se modes delivered by Aristotle (*cit. c.4. T.30*), about which Pelbartus (*Tom.1. verbo modus intrinsecus*), the Formalists with Sirectus (*art.3. partiali, and 2. principali Tract. Form.*), Maior (*1. Post. fol.71*), Tataretus (*q.3.*), Johannes de Magistris (*ibid.*), and others also treat at length, and I touched on somewhat in the Epitome (*l.1. q.2. a.2*). For their easier understanding:

Note first that one thing is commonly said to belong per se to another, as the Doctor (*quol.1. §. de 2. P.*), Gadius (*ibid.*), and Orbellus (*5. Met. c.7*) imply, when it intrinsically and necessarily belongs to it — as to be rational per se belongs to man — while conversely something is said to be applied to another per accidens when it comes to it extrinsically and contingently, as to be white or black is applied per accidens to man. The Doctor further notes (*q.15. praecit.*) and implies (*quol.9. A.*) that this condition per se can be taken in two ways: namely in propositions and in things. In the first way it constitutes a mode of inhering; in the second way it constitutes a mode of being; and in both ways such a per se condition is possible. It is possible in propositions because in some enunciations the subject is the cause of the predicate, and in some the predicate is the cause of the subject. Example of the first: in the second mode of saying per se — man is risible — because the property proceeds from the essential principles of the subject. Example of the second: in the mode of saying per se — man is an animal — when part of the definition is predicated of the defined, or the whole definition of the whole defined, as man is a rational animal. Likewise this condition is possible in things and constitutes a mode of being, excluding the principal cause, according to the Lincolnian. And this in three ways: for it either excludes the efficient and final cause — and in this way only the first cause is per se, because it has neither efficient nor final cause, being itself the efficient and the end of all things; or it excludes material cause — and in this way intelligences are per se, because they are without matter; or per se excludes being in a subject — and in this way substance is a being per se; and this mode can be reduced to material cause, because substance is the receptive of accident.

Note second that concerning the number of the modes of saying per se there is not one sense among all dialecticians. For some, like the Lincolnian in the present place, as Scotus testifies (*q.16*), admit only two modes of saying per se. Others, like St. Thomas as cited by the same Doctor there, accept only three modes of saying per se. Nor are there those lacking who devise more than four — among whom is Themistius, who adds a fifth mode. The common opinion, however, is that of Aristotle (*c.4. primi Post.*), Scotus (*cit.*), Trombetta (*Tract. Form.*

fol.45), and others in that place who enumerate four modes of saying per se. The reason for this number of four can be adduced from Trombetta (*cit. in fine pag.2*): whatever is said per se of another is said either as the predicate is of the essence of the subject — and the first mode of saying per se is had — as man is rational; or as the predicate is the proper property of the subject — and the second mode of saying per se arises — as substance is subsistent; or finally through the predicate the proper cause of the effect of the subject is expressed — or, as Tataretus says, when the subject includes the cause through which what is produced is present in it — and the fourth mode of saying per se arises — as fire heats through heat, as Scotus explains (*1. d.32. q.2. §. Contra*). All these modes share the common name of saying per se — rightly so, as Zabarella judges (*l. de propositionibus necessariis c.3*) — because Logic in the Posterior Books considers the modes of saying per se, and in the Perihermeneias the modes of stating, leaving the modes of being to the fifth book of the Metaphysics (*c.28. T.33*). Each of them, however, possesses its own proper name. For the first mode is called the mode of predicating per se, perhaps for the reason that the definition is predicated essentially and quidditatively of the defined. The second mode is called per se inhering, so named because the property which is predicated of its subject necessarily and naturally inheres in it. The third is named per se being, because it is said of those things that are per se, or that subsist per se — which the Doctor also says (*1. Post. q.31*) belongs to secondary substances. The fourth is called the mode of per se causing, because it denotes a cause conjoined with its actual effect — as is shown of fire heating through heat — and the Doctor indicates (*3. dist.7. q.1. §. Quarto*).

Note third, from Scotus now cited and (*1. d.8. q.3. T.*) and (*1. Post. q.20*), Trombetta, and the other aforementioned Formalists, that these modes have their own grades and conditions. The two foremost conditions of the first mode, implied by Aristotle (*T.30*), are these: one is that the predicate be in the subject — that is, that a natural predication be made; without this, this is not of the first mode — animal is man — as Scotus notes (*q.28. primi Post.*). The other is that the predicate be said of the subject in quid — that is, that it be the whole definition, as man is a rational animal; or part of the definition, as man is rational; or anything else proximate or remote pertaining to its essence, whether transcendental — as man is a being — or predicamental — as man is a body. To this mode are also reduced identical propositions, when the same is predicated of itself — as man is man — as is clear from Scotus (*q.15*) and is drawn from Aristotle (*1. Top. c.4*) and other places cited by more recent authors. The reason can be that in identical predication the participating cause is excluded; for the sense of the said proposition man is man is: man is per se man in such a way that no other cause is required for him to be man. Hence the philosopher adds (*7. Met.*) that the question of why man is man is no question at all, because a question presupposes one thing and seeks another; but in the said proposition nothing is presupposed and it has no other cause. Hence Brulifer (*Tract. Form.*

fol.17. pag.2) thinks that propositions of this identical kind are improperly of the first mode, because according to Aristotle cited and the common sense of the Doctors, that is a proposition of the first mode when the predicate is of the essence of the subject; but the same thing is not of the essence of itself. All the more so because in the first mode either the predicate is the whole definition or part of the definition of the subject; and this the Doctor appears to assert (*1. Post. q.10; 1. d.8. q.3. T.; and 3. d.7. q.1. D.*). To this first mode also belong negative propositions — as man is not irrational — as Scotus holds (*q.21. and quol.4. E.*); and propositions of intrinsic modes, as Smissinus asserts (*Traft.2. disp.1*) with more recent authors. The reason is that, as I said in the treatise on God the One, an intrinsic mode cannot be perfectly and adequately understood without the thing of which it is the mode. To these four per se modes correspond four per accidens modes — although Scotus (*q.18*) and other authors adduce only three per accidens modes, comprising the second under the first. The first per accidens mode is when the predicate is not of the essence of the subject nor contained under any of the grades set out — as animal is rational. The second is when the predicate is neither of the essence of the subject nor follows the essence of the same subject — as man is white. The third is when something is applied to something not existing per se — as blackness is. The fourth is when an effect proceeds from the cause assigned only accidentally — as when the man was walking, it lightened. For lightning is not the cause of the man's walking, but it happens by chance, and only a simultaneity of time of both is had — that at the same time both lightning and the man's walking occur — as is clear from (*1. Post. T.9*).

Assertion. Demonstration must be made from per se premises. So Scotus with Aristotle in the place described. Proof: demonstration consists of necessary things, from what was said in (*art.5 of this q.*); but every necessary proposition is in some mode of the four per se, as is clear from the preceding notes. Therefore demonstration is made from per se premises. It is added: the premises must necessarily be conjoined with the conclusion, as a necessary cause is necessarily conjoined with its effect — as has been established from the foregoing. But this cannot be done unless the premises are from per se things. For common and extraneous things are not necessarily connected with each other, as is clear from what Aristotle argues (*c.7*) and Maior cites (*ibidem, §. In quinta, fol.72. pag.2*) against Bryson who demonstrated the quadrature of the circle through a common cause. Therefore demonstration must be composed of per se things.

You will object, first, that what several sciences use are common principles, as is clear from the preceding assertions; but several sciences use the same principles — as I shall show of subalternate ones in the last question of this book, and can also be shown of non-subalternate ones — notably Logic, Physics, and Metaphysics, which use this or a similar principle for constructing their demonstrations: an apt definition consists of genus and difference. Therefore demonstration need not necessarily be composed of per se things. Granting the

major, to the minor the philosopher concedes this for subalternate sciences (*c.7 cited above*). For disparate sciences it can likewise be admitted, provided they are not caused through the most powerful demonstration.

You will object, second, that what is made from those things that belong per accidens to something is not made from proper things; but some demonstrations are woven from things that belong to something per accidens. Therefore not every demonstration is made from proper things. The major is known; the minor is proved from Aristotle (*2. Post. c.1*), who — as the Greek commentators note there — admits that things predicated per accidens of some things pertain to demonstration. The Greek commentators offer the example of the lunar eclipse, which is said to belong per accidens to the moon, because it does not always belong to it. Granting the major, I deny the minor; and to its proof I say that the moon can be considered in two ways: in one way absolutely, with no account taken of the interposition of the earth — and in this way the eclipse is applied to the moon per accidens; in the other way as it regards the interposition of the earth — and in this way the eclipse is attributed to the moon per se and necessarily as its property, as Aristotle plainly signifies in the passage cited, affirming that the eclipse is demonstrated of the moon by the proper quid demonstration as belonging to the second mode of saying per se, and Zabarella teaches clearly (*c.16. l.2. de propositionibus necessariis*).

Article VIII. Whether the Premises of Demonstration Are from Universal Predicate.

The final grade of necessity required for demonstration is offered and explained by Aristotle (*1. Post. c.4. T.11*), and is called the universal predicate. For since already in the preceding sections two grades of necessity — namely from all and per se — have been expressed, now the third remains to be explained. At the outset I note that the first grade of necessity can exist without the second and third, but not vice versa, as Scotus indicates (*q.28. Post.*). Likewise the second can exist without the third, but not the third without the second, as the Doctor asserts (*q.33. §. Adquæst.*). So that by these three conditions the premises of demonstration arrive step by step at the highest necessity. Moreover, lest I labor in equivocation, I note that universal is not taken here for what is one apt to be predicated of many — about which there was extensive treatment in the second book — but for a predicate that adequately and reciprocally belongs to a subject, as the Doctor interprets (*loco proximè allegato*): thus risible is a universal predicate with respect to man, to whom it belongs adequately and convertibly. Hence the universal is described by Aristotle (*nuper citato*) and received by the Doctor (*q.35*): what is from all, and per se, and according to what itself. And shortly after (*T. cit.*): the universal exists when it is demonstrated of each thing and primarily. Three necessary conditions are attributed to it: the first is that it be from all — supply in the posterior sense. The second is per se — understand in some of the four modes adduced and explained in the preceding article. The third is that the

predicate be according to what itself — that is, that it be reciprocated and adequated with the subject, as Scotus explains (*q.33. §. Ad quest.*). Hence it is clear that the last condition does not coincide with the second, as some suspect — from whom Zabarella does not seem to differ (*loco citato, and l.1. de propositionibus necessariis c.2*) — since many propositions are per se that do not have the predicate according to what itself: for sentient is indeed said per se of man, yet not according to what itself, because it is not adequated to him, belonging to others besides man, and is attributed to him not as man but as animal. Therefore I do not think that two descriptions of the universal predicate are affirmed by Aristotle, but only one, whose conditions are expressed in two places — and more in the latter than in the former. For to be demonstrated in each thing and primarily is the same as to be predicated from all and according to what itself. But since the predicate according to what itself includes the mode of saying per se, as I noted above, Aristotle therefore did not express it in the first place. Furthermore I infer that it is not the same for a predicate to belong immediately to a subject as to belong universally to the same, as certain Themistians cited by Ruuvius (*q.3. c.4*) think, following Themistius in the present place. For the universal predicate belongs to the subject primarily — that is, adequately — as the Doctor explains (*q.34*) and Averroes and Zabarella (*ibidem*) clearly teach. But genus, though it immediately belongs to the species, does not do so adequately, because it exceeds the species. Likewise difference is immediately subject to genus, though it is not its universal predicate, for the reason just given. Therefore it is not the same thing to say that a predicate immediately belongs to a subject as that the same belongs to it universally. And lest anyone in assigning a universal predicate to some subject err, Aristotle (*c.5. of this book T.12*) and onwards warns that three mistakes can be imprudently committed, which Scotus also adduces (*q.35. paulò ante §. Ad 1. rationem*). The first can happen when there is only one individual of some species — as the sun and the moon — and a property is attributed primarily to one of them as if it were a species; for example, if eclipsability is applied primarily to this moon, since many other moons are possible, such a property cannot be applied to it primarily — that is, adequately. The second error occurs when a proper property of some genus is demonstrated of its species and one imagines such a demonstration to be universal, when in reality it is not. Such deception occurs when the genus, under which many species are comprehended, is unnamed, and the property of such a genus — whose name is unknown — is granted not to the genus itself but to the species contained under it; for example, if someone attributes commuted proportion, which is a mathematical property, primarily to lines, numbers, times, and solids, when it plainly belongs to their genus — though that genus is anonymous. The third is committed when a proper property of some species is thought to be a proper affection of its genus — as if someone thought that risibility belongs to man because he is an animal.

Assertion. Both premises of the propter quid demonstration, or at least one of them, must have the universal predicate. Aristotle (*c.4*), Scotus (*q.34. §. Adq.*), and Maior (*ibid. fol.72. §. In 7. cap.*) deliver this. The first part is proved: in the conclusion of the propter quid demonstration the proper property of the subject is demonstrated of it through the middle term, which is the definition of that same subject — from what will be said below; and such a conclusion cannot be deduced unless from premises with the universal predicate, as is clear in this demonstration: every rational being is risible; every man is rational; therefore every man is risible. Furthermore, the subject of which the proper property is demonstrated is its immediate and adequate cause, as is clear; therefore the premises which are the causes of such a conclusion — in which the proper property is shown of its primary subject — consist of the universal predicate. The second part is proved: propter quid demonstrations can be made even when one of the premises does not have the universal predicate. Therefore for the propter quid demonstration it is not always required that both premises have the universal predicate. The antecedent is shown in this demonstration: every animal is alive; every man is an animal; therefore every man is alive. Here it is plainly established that the major does not have the universal predicate, as I showed before the proposition.

You will object, first, that per se is the same as according to what itself; therefore the universal predicate does not differ from the per se predicate. The antecedent is clear from Aristotle (*T.11*), who says: per se and according to what itself are the same — as per se the point inheres in the line and the straight, insofar as it is a line; and the triangle has two right angles insofar as it is a triangle, etc. The same is read in (*c.7 of the same book*) and is received by Themistius there, with Scotus' assent (*q.34. §. Intelligendum*). I distinguish the antecedent: per se and according to what itself are the same really, just as a lower predicate is really identified with a higher one — I concede; per se and according to what itself are the same formally, primarily, and convertibly — I deny; as I explained near the beginning of this article, and the Doctor touches on (*q.33. 39. §. Item si*). And Aristotle appears to express this in the passage cited, when to the condition per se he adds a third condition — according to what itself; otherwise the third condition would be pointless if it wholly coincided with the second. And (*T.16*) he assigns a rule for the universal predicate with respect to the primary and adequate subject — namely that of which the removal brings about its removal and the positing brings about its positing is the primary subject of the universal predicate — as is clear of man and risible, which are equal and convertible terms; and man being posited, risible is posited, and man being removed, risible is likewise removed.

You will object, second, that the universal predicate is the same as the reciprocal and adequate predicate, as I was observing from Aristotle. But the definition belongs to the defined as a convertible and adequate predicate, as every man is a rational animal and every rational animal is a man. Therefore it is its universal predicate, and consequently genus — which is part of the definition of the

species — belongs universally and adequately to the species; which is false and was rejected above. Granting the whole argument, the last inference is denied, because genus is one part of the definition of the species that is wider than the other part, which is the difference — that part being equal to the species itself. For this reason the notion of genus does not reciprocally and adequately belong to the species in the way the whole definition belongs to the defined, as the Doctor signifies (*1. Post. q.16. §. Ad haec*).

Article IX. Whether Demonstration Is from Proper Things.

The acceptations of property are recalled from the Epitome (*l.1. q.3. art.6*). Only this is to be sought here: I note with Hurtado (*disp.11. Sect.7*) and Fuentes (*disp.11. q.19. diff.1. art.6*) that proper is opposed to alien and common — so that proper thus taken is what proceeds not from extraneous and extrinsic principles but from intrinsic and essential principles of the thing of which it is the property, and thus belongs to it necessarily that it cannot belong to another, as I declared in the place just cited, and the Doctor touches on (*q.25. §. Adquaest.*). Proper can also be extended to what is proximate and immediate by immediacy of subject or cause, which Scotus mentions (*q.34. §. Huic dicitur*). In this sense genus and other quidditative predicates can be called proper to a thing, even though they belong to many others; and in this sense those demonstrations are said to consist of proper things that are made in the first and second mode of saying per se; while the others, made in the other modes of saying per se, do not seem to be from proper things, as the Doctor signifies (*q.26*). But if a property neither arises from an object nor inheres in it unless an extrinsic cause intervenes, and once that cause is posited the property is necessarily posited, and once it is removed the property is necessarily removed, there is without doubt a necessary link between such a subject and property, and a demonstration about these can be made — as is clear of the moon, whose property is the eclipse caused by the earth interposed between the moon and the sun. For such a demonstration is had from a per se known principle — namely, an opaque body interposed between a luminous body and a transparent one impedes the multiplication of light to such a transparent body; but the earth is such an opaque body interposed between the sun and the moon. Therefore, on account of the premise stated and the cause adduced, the moon suffering eclipse is evidently shown — as Scotus clearly inferred (*1. dist.3. q.4. §. De 2. cognoscibilibus ante E.*).

Assertion. Demonstration is composed of proper things. So Aristotle (*1. Post. c.1*) and Scotus (*ibidem q.39. paulò ante §. Ad 1.*). Proof: demonstration, as I showed in the preceding sections, must consist of premises from all, per se, and of universal predicate; but these are proper, because they belong to the subject of which the demonstration is made in the first or second mode of saying per se, as is clear from what has been said. Therefore demonstration is made from proper things. It is added: the premises must necessarily be conjoined with the conclusion, as a necessary cause is necessarily conjoined with its effect — as has

been established from the foregoing; but this cannot be done unless the premises are from proper things. For common and alien things are not necessarily connected with each other, as is clear from what Aristotle argues (*c.7*) and Maior cites (*ibidem* §. *In quinta fol.72. pag.2*) against Bryson demonstrating the quadrature of the circle through a common cause. Therefore demonstration must be composed from proper things.

You will object, first, that what several sciences use are common principles, as is clear from the preceding assertions; but several sciences use the same principles — as I shall show of subalternate ones in the last question of this book, and it can also be shown of non-subalternate ones — notably of Logic, Physics, and Metaphysics, which use this or a similar principle for constructing their demonstrations: an apt definition consists of genus and difference. Therefore demonstration need not necessarily be composed from per se things. Granting the major, to the minor: the philosopher concedes this for subalternate sciences (*c.7 cited above*). For disparate sciences it can likewise be admitted, provided they are not caused through the most powerful demonstration.

You will object, second, that what is made from things that belong per accidens to something is not made from proper things; but some demonstrations are woven from things that belong to something per accidens. Therefore not every demonstration is made from proper things. The major is known; the minor is proved from Aristotle (*2. Post. c.1*), who — as the Greek commentators note there — admits that things predicated per accidens of some things pertain to demonstration. The Greek commentators offer the example of the lunar eclipse, which is said per accidens of the moon, because it does not always belong to it. Granting the major, I deny the minor; and to its proof I say that the moon can be considered in two ways: in one way absolutely, with no account taken of the interposition of the earth — and in this way the eclipse is applied to the moon per accidens; in the other way as it regards the interposition of the earth — and in this way the eclipse is attributed to the moon per se and necessarily as its property, as Aristotle plainly signifies in the passage cited, affirming that the eclipse is demonstrated of the moon by the proper quid demonstration and belongs to the second mode of saying per se, and Zabarella teaches clearly (*c.16. l.2. de propositionibus necessariis*).

Article X. Whether Demonstration Is from Per Se Known Things.

Concerning the proposed difficulty it does not seem necessary to labor too much, nor to linger long in dissolving it, since it is universally conceded that some demonstrations are composed of per se known things — as every whole is greater than its part; body is a whole; therefore body is greater than its part — while some are not constructed from per se known things — as every weepable thing is risible; every man is weepable; therefore every man is risible. A greater contest is seen among scholastics, both external and our own, as to what a per se known proposition is and what its proper division is. For St. Thomas (*1. part. q.2.*

art.1), Cajetan (*ibid.*), Ferrariensis (*1. contra Gentes c.10*), and others of the same school assert that a per se known proposition is one in which the predicate is of the essence of the subject, and they consistently and unhesitatingly defend that every immediate proposition is per se known. But the subtle Doctor (*d.2. q.2. §. quoniam A. G. in Report. ibid. §. dico*), Lychetus, Bargius, Orbellus in that place, Pelbartus (*Tom.1. verbo Deus §.4*), and the Nominalists — among whom are Auriol (*same d. art.5*) and the greater part of the more recent — affirm that a per se known proposition is described as one that is cognized from the sole knowledge of its proper terms. Whether, moreover, for a per se known proposition a confused cognition of its terms suffices — as Faber (*Theor.7. c.1. 1. disp.14. 6.1*), Fuentes (*diff.2. a.2. q.19*), and the inseparable Scotists (*disp.13. q.3. art.1*) think — or a distinct cognition of the same terms is required, as Lychetus, Posnaniensis in the place cited, Vulpes (*Tom.1. disp.1. art.1*), and others whom Fuentes wrongly cites in the opposite opinion hold — what must be said by us according to truth and the mind of Scotus will become known through the following notes.

Note first that the per se known proposition is described by the Doctor now cited in these words: a proposition is called per se known that from its proper terms, which are something of it and as such, has evident truth — and not on account of anything else outside the proper terms does it have its evidence, but from itself alone, as every whole is greater than its part. More briefly and clearly, a per se known proposition can be defined as one that is cognized from the sole and simple knowledge of its terms. This Aristotle undoubtedly delivers (*1. Post. c.3. T.6*) saying: we know principles insofar as we know their terms — which is to say that the sole terms being understood — namely subject and predicate — with everything else excluded, the per se known proposition is immediately understood; as if what a whole is and what its part is are cognized, immediately it is cognized that every whole is greater than its part. But the efficient cause of it is not excluded from this — namely the intellect partially concurring to produce the knowledge of any thing, as Scotus affirms (*1. d.3. q.4. and quol.15.*). Nor is it called per se in contrast with a proposition per accidens; otherwise every per se proposition would be per se known, and so there would be no mediate per se propositions — which was shown to be plainly false in the foregoing. But it is called per se so that all may understand that the cognition of a per se known proposition — as to evidence — does not depend on any intrinsic cause or probative medium other than the cognition of its terms. Therefore two principal conditions are required for a proposition properly per se known, as Tataretus rightly notes (*1. Post. q.2. dub.2*). The first is that it be an immediate and indemonstrable proposition lacking a medium for its proof, as the Doctor's authority (*ubisupra §. Exhis*) establishes, because it is known per se and not through another. Although not every immediate proposition is per se known — as the same Doctor shows (*ibid. §. quoniam sub A.*) through what — the thing of whose quiddity is understood confusedly through the defined is not known except when the same is conceived distinctly through the definition.

Furthermore, if it were otherwise, any necessary proposition of the first mode — as man is an animal — all the way up to substance, would be per se known, which the Doctor infers as false (*praecit.*), because it does not have evidence from the sole knowledge of its terms. The second condition is that such a proposition be naturally apt to have evident truth from its proper terms, because the terms, as they are terms of such a per se known proposition, evidently show that the complex expression conforms to the proper notions of the terms and their relation, as the Doctor subtly deduces (*in quest. §. Ad argumenta principalia in Solutione ult. sub F.*). Hence contingent propositions are not per se known, because they are not naturally apt to have evidence from their terms — since they do not conform to the relation and notions of the terms — from (*1. Post. c.3.*). Especially because they are cognized by us through sense and experience, and by God through the decree of his will, as I wrote at length in the treatise on the science of God. But Auriol, Mastrius (*1. d.2. q.5*), and Valentia (*1. p. q.2. puncto 1*) object that the aforesaid description of the per se known proposition is insufficient: because, while true in abstractive cognition, it nevertheless has no place in intuitive cognition — as this snow is white. But such and similar propositions are known by sense and experience, and at least by divine power it can be brought about that from cognition of the terms they are not known — as if, while snow is not destroyed, God were to remove whiteness from the snow itself — which Mastrius himself admits can be done. Thus in a given hypothesis this would be false: snow is white — and from itself it would not have evidence, which that same Mastrius also thinks formally belongs to a per se known proposition. Furthermore, Aristotle (*1. Post. c.3*) denies that a contingent immediate proposition is per se known, asserting that every per se known proposition is necessary; for which reason Scotus in the question cited (*paulò ante D.*) denies that this is per se known: man is white. Therefore the description of the per se known proposition given by Scotus is apt.

Note second, from the same Scotus in the question (*§. quoniam A.*), that the proper terms of a per se known proposition are its definition — whether terms be taken for the significant sounds or for the understood concepts signified. For from (*1. Post. T.10. and 20*) the definition of the subject is the middle term in the most powerful demonstration, in which the proper property is shown to inhere in the subject — or the defined — through the definition as the middle term. If therefore the definition were not another term than the defined in the aforesaid demonstration, there would be a begging of the question, and one of the premises would not differ from the conclusion — as may be seen in this argument: every rational animal is risible; every man is a rational animal; therefore every man is risible. Here the major does not differ from the conclusion except as definition from defined; yet the major is indemonstrable and the conclusion demonstrated, and there is a process from what is known of the definition to what is unknown of the defined. Therefore the definition is a different term from the defined; otherwise in the argument just adduced there

would be only two terms, whereas every perfect syllogism requires three terms, as is the common agreement of dialecticians. It is added: a thing is cognized confusedly before it is cognized distinctly in the natural order, as is clear from (1. *Phys. T.3*); but the defined represents a thing confusedly and the definition distinctly. But the same thing cannot be prior and posterior, known confusedly and distinctly simultaneously. Hence the Parisians (*q.4. primi Phys. §. Innata*) and Brulifer (*in Epit. Form.*) add that between the defined and the definition there is a formal distinction, which can only intervene between distinct terms. Therefore the terms of a per se known proposition are the definition and the defined. Now since such terms do not express a thing in the same way — because what the defined expresses confusedly the definition expresses distinctly — for this reason Scotists at the beginning of this article rightly inquire whether a per se known proposition requires terms known confusedly or distinctly. I think this dispute must be settled and the authors reconciled if one says that in universal and supreme science — such as Metaphysics — a per se known proposition requires terms distinctly known, because its function is to know the quiddities of things distinctly, and to it the ultimate resolution belongs. But in a special science, for a per se known proposition terms known confusedly suffice, because prior is the confused cognition of things than their distinct cognition of the same things. Since therefore the special sciences in the order of teaching precede the universal science — that is, Metaphysics — as I showed in that place, and axioms and per se known propositions serve them and assist in forming and establishing their conclusions, it is evidently deduced that confused cognition of terms suffices for such per se known propositions. This doctrine is entirely Scotus's (1. *d.2. q.2. §. quoniam sub A. vers. similiter*). And more openly (3. *dist.24. q.vn. ante §. Ad aliud sub R.*) in these words: similarly natural science, as it precedes Metaphysics, has its terms known confusedly; but the Metaphysician through definition expressly expresses the distinct knowledge of those terms, and then the knowledge is more perfect when it is with Metaphysics. The same he also asserts in the Reportatio of the third (*eadem dist. §. Ad 3.*), and Lychetus and his principal interpreters follow him. Therefore it seems to me that it must be said and concluded that a per se known proposition taken universally is one that from the sole knowledge of its terms has evident truth, as is clear from the Doctor cited (*A. and infra vers. Igitur*). And it can be twofold: one that is cognized only from terms known confusedly; the other that is cognized only from terms known distinctly.

Note third, from the same Scotus (*paulò ante §. Ex his. vers. Ex hoc patet*), that the division of the proposition given by St. Thomas (1. *p. q.2. a.1. in solutione princip.*) into per se known and per se knowable is not appropriate — since the members of a good division ought not to coincide, as its canon requires. For the first member of this division coincides with the second. For a proposition is not called per se known because it is actually cognized — otherwise, with no intellect thinking, no proposition would be per se known. Rather it is called per

se known because, from the nature of its terms, it is apt to have evident truth from its terms, in whatever intellect conceives the terms. And if no intellect conceives the terms, the proposition is nonetheless per se known from itself. By this it likewise appears that there is no section of the per se known proposition into one in itself and one for us — because whatever is per se known is per se known to any intellect apprehending its terms, though it may not be actually cognized, since it is evidently known from its terms if the terms themselves are conceived. For just as a syllogism is perfect which needs nothing to appear necessary and requires nothing extrinsic for the necessity of its extremes to shine forth — since it is of necessary things whose relation between its extremes is essential and indissoluble, whether actually cognized by us or not — so that is a per se known proposition which from its terms alone made explicit possesses evident truth, whether actually cognized by us or not. Furthermore, when Aristotle divides the proposition into dialectical and analytic, he does not subdivide it into dialectical in itself and for us, nor into analytic in itself and for us. Therefore the aforesaid division of the per se known proposition is not legitimate. For the same reason the division of Aegidius is dismissed — into a proposition known to the wise and to the unwise — as is Varro's division, Scotus's teacher, into a per se known proposition of the first genus and of the second order. For the formal and intrinsic notion of a per se known proposition consists in the sole per se evidence of its terms, without any medium whatsoever, as is clear from what has been said. Therefore it is irrelevant to the per se known proposition whether it be known to the wise or the unwise, and whether it be of the first or second order, provided it enjoys evidence from its proper terms. All the more so because Scotus speaks of the objective and not the formal or mental proposition, as Theodorus notes with Fuentes (*q.19. diff.2. art.3*), against Suarez (*disp.29. Met. Sect.3. n.33*), who interprets the said Scotus as speaking of the formal proposition. For the Doctor himself does not distinguish the per se known proposition from the per se knowable — which is certainly the objective and not the formal proposition. Likewise the same Scotus adds that a proposition is per se known that from its terms is naturally apt to have evidence — which without any doubt belongs only to the objective proposition. Furthermore, it follows that the controversy between St. Thomas and Scotus is not over the name, as Vasquez (*1. p. disp.16. sect.10. n.8*), Molina (*ibid. art.2*), Hurtado (*disp.11. sect.4*), Suarez cited, and two of our more recent authors (*disp.13. q.3. a.1*) imagine. For it does not seem probable how a question about name alone would be so diligently proposed and accurately weighed, would so greatly exercise the minds of most learned men, and would engage the studies of the most subtle Doctors — as Valentia objects (*Tract. de Trinitate q.1. p.4*). I on the other hand oppose the authorities and reasons adduced just above, which plainly show that the matter itself — not merely the name — is at issue.

Assertion. Sometimes demonstration is from per se known things; sometimes not. This assertion is common to Aristotle and Scotus (*cit. 1. d.3. q.4. §. primo A.*).

The first part is proved: sometimes demonstration is composed of both premises that from their proper terms alone have evidence — as every whole is greater than its part; the natural body is a whole; therefore the natural body is greater than its part. The second part likewise becomes clear, because demonstration very often consists of mediate and demonstrable premises. Therefore demonstration is not always composed of per se known things. The antecedent is clear in this demonstration: every risible thing is weepable; every man is risible; therefore every man is weepable.

You will object, first, that Scotus in the question (§. *Ex his sub B.*) affirms that this is per se known: God is, to anyone who perfectly conceives its terms; but to perfectly conceive the terms is equivalent to distinctly apprehending those very same terms. Therefore for a per se known proposition it is necessary that its terms be distinctly cognized. Some reply that that text is not the Doctor's, but an addition by an annotator. But nearly all disciples and interpreters of Scotus assert it to be his own text — and indeed this is clearly seen (3. d.24. q.vn. ante §. *Ad aliud infra R.*), as I observed above. Therefore admitting the aforesaid text, I say that sometimes a per se known proposition requires that the terms be perfectly and distinctly conceived — as in Metaphysics and also in Theology, which is the supreme science — especially because the proper terms of the aforesaid proposition cannot be cognized unless they are distinctly apprehended. Therefore not every per se known proposition requires terms distinctly known, as I declared at length in the place cited.

You will object, second, from the same Doctor (*ibid.*), who before D says that man is white is not a per se known proposition unless it is per se known that man and white are actually conjoined; but if they were not actually conjoined, its converse would be true: no man is white. From this it is evidently collected that, according to Scotus, for a per se known proposition it is not required that the extremes be necessarily conjoined, since it is contingent that man is white. I reply that Scotus adduces this by way of example, as may be seen in his text, corroborating what he was asserting there — namely that for a per se known proposition the extremes must truly be united with each other, because no notion of something is true unless in itself it is true, as is read (*s. Met. c. de falso*): a notion false in itself is false universally. Thus it is denied that what is inferred follows, as I made clear in the first note against Maior and Auriol.

You will object, third, that the same Scotus in the question (*sub A. vers. Ex hoc patet*) reproves the division of the per se known proposition into one in itself and for us — which he seems openly to approve (*ibid.* §. *Ex his B.*), saying that this is per se known: God is — but not to us. Therefore Scotus is inconsistent with himself, and consequently the aforesaid division of the per se known proposition should not be rejected. Some, to more easily extricate themselves from this difficulty of Scotus — as Cavellus, whom Fuentes (*cit. art.2. in resp. 2. obiectionis*) follows — delete that text, asserting it to be some addition and not

the Doctor's text. But in truth the said text does not seem to be removable from the codex of Scotus, since it is plainly not an addition, as is established from its original. The same is contained in the Reportatio in the same distinction and question, and is received by all his interpreters except the two just cited. Therefore I say that no inconsistency is involved in Scotus's assertions. For the Doctor says that this is per se known — God is — because its extremes are naturally apt to cause evidence in one who perfectly apprehends such extremes. But since we do not conceive God under the notion of Deity or as this divine essence, but under the common and attributal notion — as the Doctor aptly deduces — for this reason this is not per se known to us: God is — but demonstrable a posteriori, as the same Scotus establishes in that place.

You will press: from what was said at the end of the last note, for a per se known proposition it suffices that its terms be apprehended confusedly. Therefore, since the terms of this — God is — are confusedly conceived by us, it will be per se known to us; or the aforesaid division of the per se known proposition into one in itself and for us must be conceded. I say with Fuentes cited that for this — God is — a distinct apprehension of terms is required — not because this necessarily belongs to every per se known proposition, as I showed above; but because it must be cognized from proper terms, and because the proper terms of this — God is — cannot be apprehended unless those very terms are distinctly known. Therefore Scotus maintains that for it a distinct cognition of terms is required. Since therefore God cannot be cognized by us under his proper notion of divinity, but under the common concept — as I showed at length in the first question of the Prologue and in the treatise on the cognizability of God — for this reason the cited proposition is not per se known to us.

Article XI. Whether Demonstration Can Be Made in All Genera of Causes.

Zabarella (*2. de medio demonstrationis c.5*) holds that only three genera of causes — namely efficient, final, and material — can be the middle term of demonstration. Albertus (*2. Post. Tract.2. c.12*) holds that the final cause cannot be the middle term for demonstrating. Others except the efficient and material causes. Against these stand Aristotle (*2. Post. c.6. T.11. 48*), Scotus (*ibid. q.57. Ad quaest.*), Faber (*Theor.15. c.2*), Conimbricenses (*q.3. artic.2.3*), and others commonly, who teach that demonstration can be made through all four genera of causes.

Note first that, since science — which is the effect of demonstration — is cognition of a thing through its cause from Aristotle (*1. Post. c.2. and 2. eiusdem operis c.8. T.11*), it is rightly to be investigated which cause is required for it and whether in every genus of causes demonstration can be formed. First, it is taken as certain that for demonstration a proximate and adequate cause is required, as I proved at length in the foregoing, and Zabarella pursues excellently (*ubisupra*

c.4). But a greater and more difficult doubt remains — which Zabarella himself holds (*citat. c.1*) to have not yet been adequately untangled and explained by the dialecticians — whether the middle term assumed for demonstrating is in the genus of efficient cause, final, material, or formal; and whether one cause is sufficient or whether all or several causes are necessary for demonstrating.

Note second, according to Scotus in the place cited at the beginning of this article, that from the four genera of causes named, some are causes in fieri — such as the efficient and final; while some are causes in facto esse — such as the material and formal. And the latter are likewise called intrinsic causes, because they enter into the essence of the composite and constitute it; while the former are extrinsic, and for that reason remain outside the composite and the constituted thing — about all of which extensively in Physics. Now here it is asked whether for demonstration an intrinsic or extrinsic cause is required, and whether one or the other suffices or both are required.

Assertion. Demonstration can be made through all four genera of causes, and several causes can concur to demonstrate the same thing. So Scotus with Aristotle in the places cited and (2. *Phys. c.7*), and Ferchius (*vestig.2. c.4. n.11. l.1*). The first part is proved, first, that the middle term and the cause are the same, as is clear (2. *Post. c.1*); but demonstration is made through every appropriate and necessary middle term from the same Aristotle now cited. Therefore also through every cause. Second: demonstration is a syllogism generative of science; but we can know through every cause, because the effect necessarily depends on every cause by which it is produced. Therefore we can demonstrate through every cause. Third, by induction through individual causes. Through the material cause: every thing having matter is corruptible, as is clear (1. *Phys. T.82*); man has matter — for he is composed of matter and form as every natural composite is. Therefore man is corruptible. Then through the formal cause: every thing having a soul vegetates; a tree has a soul; therefore a tree vegetates. Furthermore through the efficient cause: what prevents food from ascending to the mouth of the stomach causes health; walking after meals prevents food from ascending to the mouth of the stomach; therefore walking after meals produces health. The major is at hand because, for good digestion, food must descend to the bottom of the stomach. Finally through the final cause: what is good and causative of health must be done for acquiring health; walking after meals is good and effective of health; therefore after meals one should walk to acquire good health. The second part certainly follows from the first, and can be corroborated from that saying of the philosopher at the beginning of the first book of Physics: we consider ourselves to know each thing when we have known all its causes and principles, all the way down to its elements. Again, the same material conclusion can be caused from diverse media and diverse causes, from diverse principles and premises — as I evidently showed in this book (*q.1. art.5*). Furthermore, several causes of different orders can produce the same effect — with the common doctrine of philosophers — as is shown in the book on causes.

All the more so because any given thing is knowable through several causes on which it necessarily and essentially depends, as I was deducing in the first part of this assertion. Therefore to know something fully and perfectly it is necessary that all its causes be known; and consequently several causes can cooperate in demonstrating the same thing.

You will object, first, against the first part of the assertion: the middle term of demonstration must precede the effect, because the middle term and the cause coincide, as I observed above; and that the cause precedes its effect is beyond doubt. But the final cause is posterior to its effect, because the end is acquired last. Therefore demonstration does not occur in every genus of causes. I reply with Scotus in the question (§. *Ad 2.*): granting the major, I distinguish the minor — in execution, I concede; in intention, I deny — which must be explained in the *Physics* in the question on the final cause.

You will object, second, that the middle term of demonstration must be necessarily connected with its extremes, as is clear from the conditions assigned. But between the efficient cause and its effect there is no necessary connection; therefore demonstration is not effected in the genus of efficient cause. The minor is proved: a builder being posited, a house is not necessarily posited; and conversely, with a house remaining, the builder necessarily does not need to be, since the builder can perish while the house remains. It is confirmed: demonstration consists of proper and intrinsic things, as is clear from the foregoing; but the efficient cause is extrinsic, as also is the final cause, as I noted in the second note. I reply with Scotus in the same place: granting the major, I deny the minor; and to its proof I say that the one actually building is the cause of the house in fieri, not in facto esse. Hence it is no wonder that the builder does not exist while the house does not exist, and that the house exists while the builder may not exist. To the confirmation, I deny that demonstration always proceeds from proper and intrinsic things — as the demonstration of the eclipse of the moon and others to be adduced below will make clear.

You will object, third, that the same thing is not demonstrated by itself; otherwise there would be a begging of the question, as Zabarella argues with Scotus in the present place (*c.3. 4. l.2. de medio demonstrationis*). But if demonstration were made through the formal cause, the same would be demonstrated through the same — for form designates the essence of the thing, since it provides being to the thing. Therefore demonstration cannot be made in the genus of formal cause. Granting the major, the minor must be denied. For whether by form is understood the form of the part — which together with matter constitutes the composite — or whether it is understood as the essential and quidditative difference of the thing, while it presents the foremost and preeminent part of the essence of the thing, nevertheless it is not the whole essence of the thing — as was established in the second book of this work in the

questions on genus and difference, and in the Physics in the questions on matter and form.

You will object, fourth, that what is assumed to demonstrate something must be necessary, since demonstration proceeds from necessary things as is clear from the foregoing; but the material cause is not necessary — for according to Aristotle, matter is what a thing can be or not be. Therefore through the material cause no demonstration is had. It is confirmed, first, that from which a property emanates is the cause or middle term of demonstration; but a property flows not from matter or form but from the composite. Therefore, etc. It is confirmed, second, that the conclusion cannot be the middle term of demonstration, because the conclusion is mediated; but the middle term is not mediated; but the material cause is concluded through the formal cause, as the philosopher states. Therefore through the material cause no demonstration is made. Granting the major, I deny the minor; and to its proof I say that the philosopher is to be explained as speaking of matter taken for the individual difference, which by our authors is called the haecceity — not of the matter of the part, whether physical or metaphysical. To the first confirmation, I say that although knowable properties proceed principally from the composite, nevertheless matter and form have their own properties — as I showed in the Physics in the questions on matter and form. To the second confirmation, I say that the material cause can be demonstrated through the formal cause mediately by mediation of cause; but immediately it can be demonstrated through its proper property. Nor is it inconvenient for one thing to be prior and posterior with respect to different things.

Article XII. Whether the Circle Must Be Excluded from Demonstration and the Regression Admitted.

Most of the ancient philosophers — especially the Pyrrhonians, who admitted science of all things — concede the demonstrative circle and regression, as the Conimbricenses (*1. Post. c.3. q.1. art.1*) cite them after Zabarella (*l. de regressu c.1*); and the inseparable Scotists (*disp.13. q.4*) partially agree with them. On the opposite side, others — whose names Zabarella suppresses in the same place — followed by Suesanus (*1. Post. com.35*), banish circle and regression entirely from demonstration. Others, among whom are Scotus (*1. dist.28. q.3. §. Aliter E.*) and (*2. dist.42. q.4. §. Ad argumenta ante 1.*) and (*quol.7. §. Hic praemittenda A.*) and (*2. Prior. q.4. in fine*), Faber (*Theor.9. c.1*), Maior (*1. Post. fol.70. dub.1*), Tataretus (*q.2. dub.3*), Toletus (*ibidem q. de regressu*), and others, reject the circle properly speaking and receive the regression.

Note first that a circle, from the meaning of the name, is a transition or return from the same to the same — as is clear in the mathematical circle, in which a beginning is taken from one point by drawing a line around, and a return is made to that very same point, as Scotus clearly explains in the question (§. *Notandum*). It can further be illustrated from circular motion, which is effected

by returning to that from which the movable began its motion. In the likeness of such motion, a circular syllogism is called — from Aristotle (*1. Post. c.3*) and (*2. eiusdem operis T.15*) and the passage from Scotus now cited — when from two premises to a conclusion, and in turn from that same conclusion to demonstrating both premises, the discourse is reiterated. Now a circle can happen in four ways, which Maior and Tataretus cited mention and Scotus implies in the place cited above. First, a circle occurs when from cause to effect and conversely from effect to cause there is a progression — as every rational animal is risible; every man is a rational animal; therefore every man is risible — a demonstration from cause to effect is had. Conversely from effect to cause: every man is risible; every rational animal is man; therefore every rational animal is risible. Second, in different genera of causes. For since from (*2. Phys. T.50*) causes are causes of one another, for that reason through one cause another cause can be shown — as every syllogism that produces science proceeds from first, true, immediate things and causes of the conclusion; demonstration is a syllogism that produces science; therefore demonstration proceeds from first, true, immediate things and causes of the conclusion. Furthermore, every syllogism that proceeds from first, true, immediate things and causes of the conclusion is a syllogism that produces science; but demonstration is such; therefore demonstration is a syllogism that produces science. The first syllogism proceeds through the formal cause, the second through the material cause. Third, when some material conclusion — which I mentioned above — is demonstrated by several demonstrations, and then through that same conclusion one of the premises is demonstrated through which the said conclusion was demonstrated. Fourth, when the same thing is demonstrated through the same thing in the same way, with the same species of demonstration from immediate things. Aristotle offers this example for its understanding: if through A, B is demonstrated, and then by regressing through B, A is demonstrated — and each is a *propter quid* demonstration. This latter circle is called a uniform and simple circle; the three former are called deformed and qualified circles, which nearly all philosophers admit as possible, while they reject the last as impossible.

Note second that regression is described as a progress from effect to cause and from cause to effect — as if man is demonstrated to be rational because he is risible, and to be risible because he is rational. The prior process is a demonstration *quia*; the second is a demonstration *propter quid*. In the first process one proceeds from the effect distinctly known to the cause confusedly known; in the second process one proceeds from the cause distinctly known to the effect distinctly known. From these it is permitted to collect the difference between regression and simple circle. For in regression two demonstrations of a different kind are found — as I made clear above by examples; while in a circle both demonstrations are of the same kind and species — for each is a *propter quid* demonstration, as is clear in the preceding note — and Faber likewise notes

(*Theor. citat. c.1*). Furthermore, regression and circle differ in terms of end. For in a circle the beginning is the same as the end, as is seen in the example adduced by Aristotle; but in regression the beginning differs from the end, as is also clear from what I have just stated. Many things learnedly and eruditely said by Zabarella (*l. praenomata*) from which our two more recent authors cited are refuted, who suspect that the circle taken broadly is a genus with respect to regression and the circle properly said. For neither is a syllogism a genus with respect to the topical and analytic, as is clear from what was said in the proper article; nor is any common generic notion found agreeing with regression and the circle properly said. Therefore the circle is not to be considered a genus with respect to those two.

Note third that in regression three things occur to be considered. First, the process from effect to cause. For since effects are more sensible and evident than their causes — as philosophers with Aristotle (*2. Post. T.1. 1. Met. c.1*) teach, especially Scotus (*both ibid. in com. and also 1. d.3. q.4. and quol.7*) — second, the examination of the discovered cause and its comparison with its effect foreknown by us. For having had cognition of the effect we proceed to knowledge of its cause, weighing its conditions and properties — as Aristotle does in the Physics (*T.82*) concerning matter, noting that it is the subject of contraries, the basis of generation and corruption, the receptacle of forms, the foundation of nature, and such things, from which the essence of matter becomes plainly known to us who consider these things. Depending on the perspicacity or slowness of one's intellect, more or less time is spent. Third, from cause to effect — and the proper quid demonstration is had, generating science in us properly speaking. And all of this, after Scotus (*Quol. cit. ante B.*), Zabarella elegantly sets forth (*c.9. l. alleg.*).

Assertion. Regression must be embraced, and the circle must be rejected. This assertion is twofold. The first part is delivered by the Doctor mentioned just above, who, though he does not use the name regression there, in reality concedes and shows it, as is most clearly evident to the reader of his text. The same is committed to writing by him (*2. Prior. q.4*), (*1. de primo principio c.2*). Proof, first, from Aristotle, who (*c.3, primi Post.*), rejecting the circle, admits that the same thing can be demonstrated in diverse ways — as happens in regression through a posteriori and a priori demonstration. The same he teaches more clearly (*2. Post. c.15*), adducing the difference between the demonstration quia and propter quid, through which regression is had — which he illustrates with the example of both demonstrations, necessary for it: every non-twinkling thing is near; the planets do not twinkle; therefore the planets are near — which is a demonstration quia; then: what is near does not twinkle; the planets are near; therefore the planets do not twinkle — which is a demonstration propter quid. The same he likewise indicates (*1. 8. Phys.*) and in other places. Second, science can be acquired by us in two ways: either through effect to cause — to which the demonstration quia is assigned — or through cause to effect — to which the

demonstration propter quid serves; and this double science is produced through regression, as is clear from the description of regression delivered in the second note. Therefore regression must be received. The major is the common doctrine of all dialecticians, proved by our Doctor in the Quolibeta cited as may be seen there. Third, the effect can be known while its cause is unknown — as is clear of science acquired through experience, which was produced by the ministry of the senses through knowledge of many singular effects; and to prior philosophers the effects became known while their causes escaped them. Hence they were moved to hunt out the causes of those same effects, as Aristotle testifies in the passage cited. And this can be shown conveniently of the motion of the heavens, of the ebb and flow of the sea, and other effects known to us while their causes are unknown. Therefore, diligent examination and accurate inquiry being applied, if the causes become known, from the causes themselves one can turn back to their effects — in which way a useful regression is effected in the acquisition of the sciences. The second part is expressly defended by Aristotle (*1. Post. c.7*) and Scotus cited at the beginning of the article, and is proved, first: the same with respect to the same cannot simultaneously be prior and posterior, more known and less known in the same respect; but if a simple and formal circle were conceded, the same with respect to the same would simultaneously be prior and posterior, more known and less known in the same respect. Therefore a simple and formal circle is impossible. The major is at hand from the laws of contradiction adduced elsewhere. The minor is shown: the premises are prior and more known than the conclusion, from what was said above; but through a circle, the conclusion — through transposition — becomes one of the premises, and the other of the premises becomes the conclusion. Therefore those absurdities just recounted are rightly inferred. Second, it is impossible for the same thing to be demonstrated by itself; but if a circle were given, the same would be demonstrated by itself. Therefore a simple circle is impossible. The major is known from what is required for demonstration. The minor is proved: for if, for example, A is the cause of B, and in turn B is the cause of A, then A will also be the cause of itself — because what is the cause of a cause is the cause of the caused thing in the same genus of cause; but the premises — namely A — are the cause of the conclusion — that is, B; and afterwards the conclusion is the cause of the premises, because through the conclusion the premises are demonstrated. Therefore the conclusion B will be the cause of itself, because it is the cause of its own proper cause. And so the same would be demonstrated by itself — which is absurd. Third, the circular demonstration is made only in equal and reciprocal terms, as the Stagirite writes in the present place and (*2. Prior. c.5*): for as is clear from the first note, a circle is effected whenever we deduce the minor from the conclusion together with the converse of the major, or we collect the major from the same conclusion together with the converse of the minor. But reciprocal and convertible terms are few; while there are many demonstrable things — yet not all fall into demonstration, as those Ancients at the beginning of this article

imagined, against whom Aristotle forms these three arguments. Therefore the demonstrative circle is vain and empty.

You will object, first, against the first part of the preceding assertion: when we proceed from effect to cause, either we know the cause or we do not; if the latter, just as it is pointless for someone to proceed to what he does not know — because even if it presents itself to him, he cannot recognize it — similarly it is to no purpose for someone to investigate the cause of some effect if he is ignorant of it, because even if it presents itself to him, he will not be able to recognize it. If the former, it is useless for us to proceed from cause to effect, since we already know both cause and effect and clearly know that the effect depends on the cause through the prior process; and for that reason regression is pointless and superfluous. I reply that in the first process the cause is cognized by us confusedly; but in the second process distinctly. Therefore we proceed from confused to distinct cognition; and this order nature presents and Aristotle maintains — especially in physical matters, as is clear from the first book of *Physics*. Those who rely on such an argument therefore err, not recognizing that between science and ignorance there mediates confused cognition — as the philosopher rightly distinguishes (*1. Post. c.1*), responding to the sophistical trick of Meno who abolishes science as something new.

You will object, second, against the second part of the assertion, that in causes a simple circle is effected; therefore also in demonstrations. The consequence is at hand, because demonstration is had through a cause. The antecedent is supported by the authority of the philosopher (*2. Phys. c.3. T.30. and 5. Met. c.1. T.2*): causes are causes of one another — the efficient cause causing the form, and the final the efficient; matter likewise causes form, and form matter. Again (*2. Post. c.15*): from vapor rain is demonstrated, and from rain vapor. Then (*2. Caeli T.59*): it is shown that the stars are immobile because they are spherical, and that they are spherical because they are immobile — where an apparent circle is seen. I reply that the argument concludes indeed in a different genus of cause, not in the same genus of cause — which is the entire point of the difficulty.

You will press: act is the efficient cause of habit, and yet habit, generated from repeated acts, is the effective cause of acts, as Scotus proves (*1. d.17. q.2.*). Therefore this holds as much of a different genus as of the same genus of cause. I say it is certainly probable that a habit concurs effectively in the production of subsequent acts; yet the opposite is also plausible, as the Doctor shows in the place cited, and the matter is still under judgment. Given the affirmative side — which is more common and probable, and toward which the Doctor leans more — I say that habit is productive and effective of subsequent acts, not of prior ones — those, namely, that precede the habit itself. For this reason no absurdity is deduced, since in the same genus of efficient cause the same thing with respect to different things can be both cause and effect — as Peter is the father of

Francis, and then Francis is the father of Anthony; but with respect to one and the same thing, the same thing cannot in the same genus of cause be both cause and effect.

Article XIII. What is the Middle Term of the Most Perfect Demonstration?

Having examined and rejected many opinions of logicians on the question of the middle term of demonstration — by Baldwin in *Quest. de medio demonstrationis* cap. I, by Faber *Theor. X*, cap. I, by the Coimbrans 2. *Post. quæst. un. art. II*, and others — I propose four principal positions for examination. The first is defended by Zabarella (*cit. 1.2.*), who attempts through several lines of argument to prove that any genus of cause can serve as the middle term of the most perfect demonstration. The second belongs to Albert and Aegidius (2. *Post. quæst. de medio demonstrationis*), and is attributed to Averroes (1. *Post. com. XI**), *who maintain that the middle term in the most perfect demonstration is always the definition of the passion and never the definition of the subject. The third is defended by the Doctor* (1. *Post. quest. LVI*; 7. d. 3. *quest. VI*, §. *Ad quest. Sub M.*; and 3. d. XIV, *quest. I, A.*; and *ante quæst. I Univers.*, as Sarnanius notes there, p. 23), *followed by all his disciples and in part by the Coimbrans (alleg. art. III), with Zabarella observing (cap. II, l.* I*, prærecensiti)* that St. Thomas (lect. I secundi Post.) does not diverge from them — these authors teach that the middle term of the most perfect demonstration is the definition of the subject. The fourth holds a position intermediate between the two just mentioned and belongs to certain more recent thinkers, notably the Thomists and the Coimbrans, who assert that the middle term of the most perfect demonstration is simultaneously the cause and the definition of both extremes, namely of the subject and of the passion.*

Recall, and supplement with what was established above in Article X of this Question, that demonstration can indeed be effected through every genus of cause, though the question of which genus of cause yields the most perfect demonstration was not settled there — it is to be resolved here. To proceed more expeditiously and conveniently, we must call to mind what was said above concerning demonstration and its species, as well as the conditions required for it. Above all else, it must not be passed over what is meant by the name "most perfect demonstration" and how it is distinguished from other kinds of demonstration. First, it must not be supposed that the most perfect demonstration constitutes a species of demonstration distinct from demonstration *propter quid*, which is subdivided into primary and secondary. The primary proceeds through the proximate and immediate formal cause and possesses all the prerequisite conditions; the secondary proceeds through another cause of a different genus and lacks one or more of the conditions necessary to it. The name "most perfect demonstration" is not found in the writings of Aristotle, as Zabarella carefully notes (*cap. XVII**, lib. alleg.), *having been invented by later philosophers, yet it is received by all as fitting and apt. All the more*

so since, as demonstration is the instrument of knowing, it ought by right to take its name from its highest end, which — in the judgment of Aristotle (1. Post. cap. X) — is the most excellent science acquired through the proximate, intrinsic, and formal cause. Accordingly, the most perfect demonstration — which strictly merits the name "demonstration" or "demonstration simply," as Zabarella (cit.) attests — is that which possesses the middle term, or intrinsic immediate and adequate cause, together with the other conditions handed down and examined in the preceding articles.*

Recall also, from what was established in the *Summulae*, that in every syllogism — whether topical or analytical — three terms are found: one is called the major extreme, or passion; another the minor extreme, namely the subject; and the third is called the middle term, which is assumed in order to demonstrate the passion of the subject. For example, "rational" is the middle term assumed by the arguer to demonstrate risibility of man, preserving the required mode and figure for the proper construction of the syllogism. Now, the passion flows from the subject, being really identified with it, as the Doctor (*quæst. cit.*) affirms. The middle term through which the inherence or indwelling of the passion in its subject is demonstrated is called the form and definition of that same subject — as the Coimbrans (*ibid. art. I*, loci pracit.*)* note from Aristotle (2. Post. cap. XI*). *The reason is that the intrinsic and essential form of the subject, which is its ultimate constitutive difference, is its noblest and most excellent part, and denomination comes from the nobler part, as the interpreters of Aristotle observe with him (7. Met. ad T. XIV,* XV*)*. Therefore, since the middle term of demonstration is the principal part of the subject and the intrinsic cause of the passion — and since the passion is commonly called a proper accident flowing by emanation — the most perfect demonstration consequently participates in the middle term or intrinsic formal cause; whereas demonstrations that are not most perfect can employ a middle term that is an extrinsic cause, which is called a cause by transmutation, which a common accident obtains, as Scotus notes (*in quæst. §. Sed si passio*). Thus the eclipse of the moon arises from an extrinsic cause, namely the earth interposed between the moon and the sun; similarly, thunder is produced by an extrinsic cause, namely the extinction of an exhalation in a cloud.*

To make this clearer: from Scotus (*cit. §. Ad quest*) there is a twofold accident: one common and one proper. The common accident follows a singular subject; the proper accident follows a universal subject, for it is caused by the essential principles of the species and is demonstrable through the intrinsic form of its subject. Not so the common accident, between which and its subject there is no necessary connection of the kind required among demonstrables. Furthermore, the Doctor adds (*quest. XL*, §. Ad* I arg.*): "This moon is eclipsed" is contingent, and likewise "the earth is interposed between the sun and the moon," and in general, what happens frequently is contingent. What falls within demonstration is necessary; and, as the Lincolniensis says, such things are taken with the circumstances that make them necessary — as I showed in Article VIII of this

Question — and this is further illustrated by the same example given there, namely when the sun is at the head or tail of the Dragon, and the moon in the same position, the moon is eclipsed on account of the earth's interposition between the sun and the moon. This is especially so because philosophers speak not of actual eclipse but of aptitudinal eclipse, as John of Mairs (*2. Post. quest. ult.*), the Venetian (*cap. IV primi Post.*), and Zabarella (*1. de medio demonstrationis cap. VII**)* particularly note. From these considerations it is gathered, with Scotus (*quæst. LVII**), *that not every demonstration propter quid proceeds through an intrinsic cause, but sometimes through an extrinsic cause — as in the demonstration just cited, which is not the most perfect, according to Faber (Theor. XIV), followed without division by all Scotists (disp. XIII, quæst.* II*, art.* II*). That such a demonstration is nonetheless propter quid the Doctor plainly declares (quest. LIV,* LVII*), against the objection of those more recent authors who follow Faber (cit.), a matter I have amply demonstrated above. Finally, observe from the same Doctor (q. LVI, §. Ante ad* I arg.)* that the passion is called "first" and "last" term in different respects: it is called the first term with respect to predication, because the passion is always directly predicated and never made subject except indirectly; yet it is called the last term with respect to the order of nature, since the passion is posterior in nature to the subject and to its principles, deriving its origin from them, as I showed above.

First Assertion: The definition of the passion is not the middle term of the most perfect demonstration.

So holds Scotus (*loco proxime alleg. §. Ad quest.*). Proof: First, that which, when known, still prompts inquiry into the reason why a thing is so, is not the middle term of the most perfect demonstration; but when the passion is known of the subject through the definition of the passion itself, there remains inquiry into the reason why it inheres in the subject. Therefore the definition of the passion is not the middle term of the most perfect demonstration. The major is evident, since the demonstration under present discussion proceeds from first and immediate principles. The minor is also clear, since a definition of this sort does not constitute the reason for the passion's inherence in the subject. Second, that which produces the most perfect science — such that it depends on nothing else for its being or its knowability — is the middle term of the most perfect demonstration. But the definition of the passion depends for its being and its knowability on the subject and is caused by the subject's essential principles, as I noted above. Therefore the definition of the passion cannot be the middle term of the most perfect demonstration. Furthermore, cause and middle term are interchangeable, as established above; therefore, since the cause of the passion is the subject, the definition of the passion cannot be the middle term of the aforesaid demonstration. Again, if the definition of the passion were the middle term of that demonstration, a *petitio principii* would occur; for in exactly the same way one accepts that man is risible as one accepts that man is capable of laughter — which is the formal definition of risibility itself, the passion of man. Finally: the opponents deny that the middle term of such demonstration is the

definition of the subject on the ground that since its premises must be immediate, the minor would be mediate; yet with the definition of the passion as middle term, the minor would equally be mediate, because the passion inheres in the definition of the subject by means of its own proper definition. Therefore, turning the argument against the opponents, it is concluded that the definition of the passion is not the middle term of the most perfect demonstration.

Second Assertion: The definition of the subject is established as the middle term of the most perfect demonstration.

So holds Scotus (*ubi supra, præsertim quæst. LVI post §. Ad q.*). First proof: from Aristotle (*2. Post.*), as cited by Tartaretus, who writes that the middle term in demonstration is the reason for the ultimate term, which is the subject — for the reason assigned at the close of the third note. Moreover, as the Doctor (*cit.*) also notes from the same Aristotle, if some passion is to be demonstrated of a subject, it ought rather to be demonstrated through C, which is the definition of the subject, than through B, which is the definition of the passion. Aristotle's reason (*ibid.*) is that C, the definition of the subject, is the cause of A, the passion, and likewise of B, the definition of the passion. The same is confirmed at (*4. Phys. T. LI**; *1. de anima T.* XI**; *2. eiusdem operis T.* XII**). *Second: that which is the proximate and immediate cause of the passion demonstrable of the subject — from which it immediately flows — is the middle term of the most perfect demonstration. But the definition of the subject is of this kind. Therefore the definition of the subject is the middle term of the most perfect demonstration. The major is proved: the most perfect science, which is the effect of the most perfect demonstration, is through the proximate and immediate cause, as is clear from the definition of science (1. Post. cap. II)* and from the conditions of principles and premises treated at length above. This is also signified at the end of the second book of the Posterior Analytics, as Scotus (loco ante cit.) attests. The minor is shown: first, because once the subject is posited, its passion immediately emanates from it, and when the subject is removed, the passion itself is removed; second, because the passion flows from the quidditative principles of the subject and is inseparable from the subject itself — therefore the subject is the proximate and immediate cause of its proper passion. Third: the most perfect demonstration proceeds from first, true, and immediate principles that are causes of the conclusion, as established above. But the syllogism in which the passion is concluded of the subject through the definition of the subject proceeds from true, first principles, etc. Therefore the definition of the subject is the middle term of such demonstration. There is the further point that what is the root and primary cause of all demonstrables is the middle term of the most perfect demonstration — composed as it is of first and immediate premises. But the definition of the subject is the root and immediate cause of all passions demonstrable of the subject. The major can be supported from Aristotle's statement (*Met. cap. IV**)* that what is the principle and cause of others' being such is maximally such — supplying this for univocal causes: if fire*

is the cause of other things being hot, fire itself is maximally hot. The minor can be shown from flability, visibility, and admirability, which in the view of many are passions demonstrable of man, ordered among themselves such that one is demonstrated through another, up to the last, which is demonstrated through rationality — the definition of man or its principal part — as Aristotle intimates (*1. Post. cap. XX**)*.

Third Assertion: The middle term of the most perfect demonstration is not both definitions together — that of the major and that of the minor extreme.

This follows from what was said in the two preceding assertions and is assumed by the Doctor and indicated by Aristotle (*1. Post. T. XXII**; *2. eiusdem operis T. II**). *First proof: of one effect there is one total and adequate cause, as is clear in natural philosophy and in the book of causes, and as the Philosopher teaches (2. Post. cap. XVII); whence Averroes (1. Post. com. XLVI)** adds that of one thing there is one demonstration and one definition, because there is one formal cause. Therefore the middle term of the most perfect demonstration cannot be both definitions — of subject and of passion — but only the one established above. Second: the middle term of demonstration is one thing per se and one cause per se; but both definitions of both extremes are not one per se, as is clear. Therefore the middle term of the said demonstration is not composed of both definitions of the said extremes. From these points and from what was established earlier, it is evident that the middle term of the most perfect demonstration is of no other genus than the formal cause, which is called the quiddity and essence of the subject; the remaining causes are extrinsic — as the material cause, which is more ignoble and inferior.

Objections against the First Assertion.

First objection: that which is the reason for the first term is the middle term of the most perfect demonstration; but the definition of the passion is the reason for the first term. Therefore the definition of the passion is the middle term of the most perfect demonstration. The major rests on the authority of Aristotle (*2. Post. T. XXV**), *who demonstrates it by the following analogy: that leaves fall from the vine is demonstrated through this middle term, "the sap congealing at the junction of leaves with branches," as Scotus (quæst. LVI, ferè in initio)** reports. Confirmation from the same: Scotus (*ibid. cap. II**)* says that the eclipse of the moon is demonstrated through the definition of the eclipse itself, and the concord of sounds through the definition of consonance itself; and at (*T. X eiusdem lib.*) he adds that the middle term for demonstrating thunder is the definition of thunder itself. Therefore the definition of the passion is the middle term of the most perfect demonstration.

I deny the major. In response to its proof I say, with Scotus (*cit. §. Ad I arg.*), that Aristotle does indeed assert there that the definition of the passion is the middle term of demonstration — which I also grant together with the same Doctor —

but not that it is the middle term of the most perfect demonstration, as the authors of the first opinion contend. The same reply can be made to the confirmation. Or one may say that this argument and its confirmation conclude concerning the causal definition of the passion, not its formal definition, which is what is at issue here.

Second objection: the most perfect demonstration proceeds from what is more immediate and prior; but the demonstration whose middle term is the definition of the passion proceeds from what is more immediate and prior. Therefore its middle term is the definition of the passion alone. The major is clear from what was said. The minor is shown: since the passion is more immediately predicated of its own definition — as when one says "what is suited to instruction is instructible" — than of the definition of its subject, as in "a rational animal is instructible." First confirmation: from Aristotle (*1. Post. cap. VI**)*, the extremes and middle must be of the same genus; but the passion belongs to the category of quality, therefore the middle term will be of the same genus and category of quality — which can only be the definition of the passion itself, since the definition of the subject belongs to the category of substance just as the subject does. Second confirmation: the middle term of the most perfect demonstration must be midway by position — that is, prior to the passion and posterior to the subject. But only the definition of the passion is of this kind, being posterior to the subject and prior to the passion. Therefore the definition of the passion is the middle term of the most perfect demonstration.

I concede the major and deny the minor. In response to its proof, I say that a proposition is called immediate not because it is through a cause proximate to the effect — as the argument infers — but because it does not have another cause through which it can be demonstrated of the subject. The definition of the passion is not of this kind, since it can be demonstrated through the definition of the subject, which is its proximate and immediate cause, and also the first among all demonstrables, as I noted above. In response to the first confirmation, Scotus (*alleg.*) replies that the extremes and middle are said to be of the same genus — that is, of the same generating genus — because the same generating principle produces both the principles of the subject and its properties; for what produces man consequently produces his properties, namely flability, risibility, and the like. Or one may say that the passion of the subject is reduced to the genus or category in which its subject is placed, as I taught elsewhere with Scotus. In response to the second confirmation, I concede the major and deny the minor. It is sufficient for the middle term to be a means of knowability — that is, to be the cause of knowing the passion's inherence in the subject — but it is not necessary for it to be prior or posterior in order. This is clearly evident from demonstration from effect, in which the effect, which is posterior to its cause, serves as the middle term — as the two recent interpreters of Scotus noted above after Tartaretus, whom they cite.

Third objection: the science produced by the most perfect demonstration is the science of the passion; therefore the middle term of such demonstration is the cause of the passion; but the definition of the passion includes the cause of the passion, since the perfect definition of an accident includes the subject of which it is an accident. Therefore the definition of the passion is the middle term of the most perfect demonstration.

I distinguish the antecedent: the science obtained through the most perfect demonstration is the science of the passion through the formal definition of the passion — I deny; through the causal definition of the passion, which is the form of the subject itself — I concede. For thus the definition of the passion includes the subject, just as every quietative and perfect definition of an accident involves the subject. For this reason it is called a definition by addition, as I noted in the *Epitome* in the article on definition.

Fourth objection against the Second Assertion: if the definition of the subject were the middle term of the most perfect demonstration, a *petitio principii* would occur. The same thing would be proved by the same thing, since definition and defined are identical, as Aristotle plainly teaches (8. *Top. cap.* IV*, loco* L*)*, saying that one of the modes of begging the question is when the defined is proved through the definition and vice versa. Confirmation: the most perfect demonstration is composed of first principles, as I have frequently premised; but if its middle term were the definition of the subject, it would not be from first principles, because the subject is the last. Therefore the definition of the subject is not the middle term of the most perfect demonstration.

The consequence is to be denied, because definition and defined differ formally, as Scotus and his followers Brulifer and the other Scotists hold (*Tract. Formalitatum*). Moreover, the argument proceeds from the distinct knowledge obtained through the definition to the confused knowledge obtained of the defined — as the Doctor (*cit.*) carefully observes in his solution of this argument. As for Aristotle: Scotus, expounding him, says: if the predicate is shown of the defined through the definition where the predicate more evidently inheres in the defined, a *petitio principii* occurs; but if that predicate more evidently inheres in the definition, there is plainly no *petitio principii*. In response to the confirmation, I say with the same Doctor that demonstration proceeds from first principles — that is, from propositions that are self-evident, or in the other sense explained above. Whether the subject ought to be called first or last I made plain at the close of the third note.

Fifth objection against the Third Assertion: Aristotle (2. *Post. cap.* IV*, T.* V*, and T.* I *ibid.*) writes that the "what is it" and the "why is it" are the same, which he illustrates with the example of the eclipse and other cases to be seen there. Therefore the middle term in the most perfect demonstration embraces both the definition of the subject and the definition of the passion: since the middle term must be the cause of the passion's being simply, and this by reason of the

passion's formal definition; and of the passion's existing in the subject, and this by reason of the causal definition of the subject — and accordingly the middle term contains both definitions. Confirmation: the middle term is that through which the passion and the subject are necessarily connected to each other; therefore the middle term is the definition of both extremes, since the necessary connection depends on both extremes.

I respond that the aforesaid questions are the same according to the thing but differ with respect to the mode of inquiry — as Scotus (*1. Post. quæst.* LIV*, §. Ad quæst.)* and Tartaretus (*2. Post. quest.* I*, dub.* II*)* note. Thus the said questions may be said to be identified because they seek the cause of a thing — whether simple or complex — yet, in the judgment of Averroes, they do not properly coincide, because *propter quid* properly regards the external cause, whether efficient or final — as is clear from Aristotle's example of the eclipse, produced by an external cause, namely the interposition of the earth — while *quid* regards the internal cause, which is the form and essence of the thing itself. In reply to the objection formally stated: granting the antecedent, the consequence is denied, because the middle term of such demonstration is the causal definition of the subject, as I showed above. In response to the confirmation, I concede the antecedent and deny the consequence, since the connection depends on the definition of the subject as proximate and immediate cause, not on the passion — even though it also depends on both extremes.

Question IV. On the Effect of Demonstration.

Having treated at length in the preceding question of demonstration as the cause of science, I have now judged it opportune in this final question to discuss its effect, which is science itself — presupposing many things already discussed and to be discussed elsewhere, so that this work I have begun and elaborated may be brought to completion.

Article I. Whether Science Exists.

Three opinions of the philosophers once held sway. Two were utterly extreme — recalled and refuted by Aristotle (*1. Post. cap.* III*)* and by the Doctor (*ibid. in initio eiusdem lib., and 1. distinct.* III*, quæst.* IV*, §. Primo infrà A.)* — and the third, a middle position, is the one best discovered and set forth by the Stagirite in the present work, to which later philosophers readily adhere and subscribe. The authors of the first opinion are the Pyrrhonists, also called Sceptics, Aphoretics, and Epochists, as the Coimbrans (*in comm. præfati cap.*) testify, and who are called Academicians by Scotus (*præcitato*) — men who deny all knowledge of things and admit universal ignorance. The proponents of the second opinion are called Platonists, as the Doctor (*ubi supra*) reports — or followers of Empedocles, as the Coimbrans (*mox allegati*) hold — who suppose there to be science of all things. Those who take the middle path are all the Peripatetics, with their two leaders — the author just named — who teach that

there is science of some things, against the proponents of the first opinion, and not of some things, against the defenders of the latter. See Ferchius (*vestig.* VI*, cap.* IV*, numero* XI*)*.

The acceptations of "science" as adduced by Scotus (*lib.* I*, quæst.* II*, artic.* II*, not.* II*)* are to be presupposed. It should only be noted here that in this place we are dealing chiefly with science taken properly and strictly, as it is the effect of demonstration — whose definition will be set forth, carefully and accurately discussed, in the next article.

The assertion is: certain things fall within the scope of science, while many things remain unknown to us. This assertion is twofold, and both parts are defended by Aristotle and by Scotus (*præcit.*) and by the remaining younger philosophers. The first part is proved: first, from St. Augustine (*lib. de vera religione*), who doubts whether anything can be known but does not doubt about doubting — he is certain of it — and one is not certain except of what one knows; therefore he who doubts whether he knows anything must necessarily concede that he knows something. Again from the same saint (*lib. II contra Academicos*): when the Academicians claim that we know not what is true but only what is probable, they do not attend to what they are saying; for if we do not know the true as it is, it follows that we would not know what is probable. Just as it is impossible for someone to know that Chrysippus resembles Socrates without knowing Socrates himself in any way. Relevant here also are other passages from the same Augustine adduced by Scotus (*in primo nuper cit. A.*), to which I add (11. *Ciuit. cap.* XXVI*, 19. cap.* XVIII*). *Second: there are things that are necessarily and perpetually connected with each other, one of which is demonstrated of the other — for instance, a passion of its subject. Therefore of some things science is obtained. The antecedent is proved: it is demonstrated that a triangle has three angles, that man is risible, and other such things. Add what Euclid demonstrates in his work, and what Aristotle and other philosophers demonstrate throughout. Relevant here is what Scotus (proximè recensitus) teaches: that the form of a perfect syllogism is naturally evident to everyone, as is clear from its definition (1. Prior. cap. I). And the science of the conclusion depends only on the evidence of the principles and on the evidence of the syllogistic inference. Therefore, any demonstrable conclusion can be naturally known to any person from premises that are self-evident. Hence, one who possesses a perfect demonstrative syllogism — which is the cause of science — and likewise knows the demonstrable thing to be demonstrated, thereby possesses science. Furthermore, science concerning knowable things is generated through experience, as Aristotle (1. Met. cap. I)* and Scotus (ubi supra) assert, and the Doctor pursues this at length and learnedly, both there and at (4. distinct. XLIII*, quæst.* II*, §. Respondeo infra D.). Moreover, the desire for knowledge naturally innate in us, from (1. Met. cap. cit.), must not be frustrated — since God and nature do nothing in vain, from (1. de Cælo T. CCCXX; 3. de anima T.* XLV*). Finally, science is the perfection of man, and in the true knowledge of God above all does his happiness principally and incipiently consist. It cannot therefore be denied that some things are known to us. The second part is easy to prove: since science is*

knowledge of a thing through its cause, and since we are ignorant of the causes of many things — why the magnet attracts iron, amber attracts chaff, the remora halts a ship, the torpedo numbs the hand of the fisherman, and the like — it plainly follows that we do not have science of all things. Moreover, science is of eternal, necessary, and universal things, as I have repeatedly urged and proved above; but many things are contingent, temporal, and singular; and what depends on the divine will is hidden from us, according to (Rom. XI): "For who has known the mind of the Lord, or who has been his counselor?"*

First objection: with Scotus (*1. Post. quest. X*)* on behalf of the Academicians. Science taken properly is effected through demonstration, by the agreement of all; therefore, since principles are known, they ought to be known through demonstration; but principles cannot be demonstrated; therefore they cannot be known. The first consequence is clear: apart from demonstrative science there is no other science. The subsumed claim is proved: either the principles are immediate — in which case they are not known, since they lack the middle term required for science — or they are mediate, in which case they are either known through other middle terms, and those through yet others, and so on to infinity; therefore there is no science of them, since the infinite cannot be known by any created intellect.

Granting the antecedent, I deny the consequence. For first and immediate principles are indemonstrable, as Aristotle (*1. Post. cap. II**; *4. Met. T. XXVI*)* writes, cited by the Doctor (*1. distinct. II**, *quæst. IV**, §. *De tertiis ante G.*)*. Indeed, principles and conclusions are known by distinct habits: the former by the habit of intellect, the latter by the habit of science. And so there is no objection in favor of the Academicians.

Second objection: all our cognition is born through the ministry of the senses, according to the saying of Aristotle in the *De sensu et sensato*, "nothing is in the intellect that was not first in the sense"; yet we experience that the senses frequently err — both in dreams and in waking — as Raconius demonstrates at length (*disp. de demonstratione, sect. III**, *quæst. II**, *artic. I*)*. Above all with respect to sight, which judges a stick in water to be broken and bent, though it is in fact whole and straight; similarly, it apprehends the sun as though it were a foot in diameter, though in fact it exceeds the entire earth in size; again, what is truly white or black we see through red glass as red; and other such things to be adduced and examined in the *De anima*. Therefore nothing certain, nothing undoubted and evident is to be asserted.

I respond with Scotus (*citato ante G., and quæst. III univers. in solutione tertii*) that our intellective knowledge comes from the sense as an occasion, not as a cause — thus the major is distinguished and the philosopher's dictum is explained. As for the minor: I say that a badly disposed sense does indeed err, but a well-disposed sense, properly approximated, with an unimpaired medium, does not deceive at all with respect to its proper sensible — as Scotus excellently teaches (*loco citato, §. Quantum ad III**, *L. and M.*). Above all because a wandering sense can be

corrected by the intellect, as I shall show at length in the place just cited. See Bonet (2. Met. cap. V).*

Third objection: it is possible that just as a conclusion is demonstrated through premises, so premises are demonstrated through the conclusion — and that everything is shown by mutual and circular demonstration. Therefore everything can be known through circular demonstration. I respond that this argument has already been dissolved. For in Article XI of the preceding question, circular demonstration was rejected by me as useless and empty.

Article II. What Science Is.

The Subtle Doctor (*1. Post. quest. I**, and ** X eiusdem operis*), drawing on the Lincolniensis, enumerates four acceptations of science, which do not seem to differ greatly from those I presupposed in the preceding article from the places cited there. I therefore do not pause over their investigation and explanation — they are to be seen in those places. Here I only note that in Aristotle, science taken broadly means that both principles and conclusions drawn from them are known. For the same Philosopher says in the text that principles are known more than the conclusion. But science taken strictly means that only the conclusion is known — as the same Philosopher says both here and in (*6. Eth. c. III**), and Bonet (*1. Met. cap. II*): *science is of conclusions, and understanding is of principles. And since there are two kinds of demonstration — quia and propter quid — there are likewise two kinds of science: science quia and science propter quid, that is, through effect and through cause. Science taken most properly of all is defined by Aristotle (1. Post. cap. II)* as: knowledge of a thing through its proper cause; that is, in Scotus's interpretation, science is certain, evident knowledge of a necessary thing through its proper cause, obtained through syllogistic discourse.* These conditions, drawn from the cited Aristotle, are set forth and explained by the Doctor (*1. Post. quest. I**, and ** III Reportat. distinct. XXIV**, *quest.* I**, §. *Ad quæst.**). Science thus understood is divided, according to Scotus (*1. Post. quest. nunc alleg.*), into actual and habitual. Actual science is: *certain and evident knowledge of a necessary object through its proper cause, actually acquired through syllogistic discourse.* Habitual science is: *a quality acquired from repeated scientific acts, facilitating the intellect to operate scientifically.* Note further, following the Parisian masters (*quest. I primi Phys.*) after Scotus (*2. Post. quest. I*), that the proposition properly knowable is the necessary and doubtable proposition which by nature is apt to become evident through evident propositions applied to it through syllogistic discourse; since this coincides with the scientific conclusion of which there is science, it requires no further explanation or conditions distinct from those enumerated.

The assertion is: the definition of science given above is correctly formulated. So Scotus (*1. Post. quest. X**, §. *Ad quest.*, and in other places)*. This is clear: for into it are assigned the genus — namely, knowledge — and the difference, indicated by its remaining clauses as shown above. Moreover it contains nothing

superfluous and nothing lacking, and through it the nature of science itself is distinctly and clearly explained. Therefore it is a legitimate and fitting definition.

First objection: principles are known more than the conclusion, as Aristotle proves in the present (*cap. II**)* through the axiom "that on account of which each thing is such is itself more so"; but science of indemonstrable principles is not effected through a cause or middle term, of which they are devoid; and similarly science of the conclusion is not acquired through a cause. First confirmation: our cognition takes its beginning from what is more known to us, from (*1. Phys. T. II**)*; but what is more known to us is not causes but effects, as is clear. Therefore our science is not obtained through a cause. Second confirmation: if science were through a cause, perfect science would never be had unless the first cause were perfectly known; but the first cause is known by us only imperfectly and confusedly with respect to common predicates, as is clear from the first question of the Prologue.

I respond: the argument concludes concerning science taken broadly, not concerning science taken strictly, as I noted near the beginning of this article. To the first confirmation: I say it holds for science from effect (*a posteriori*), not for science from cause (*a priori*), regarding which the aforesaid definition of science is given. To the second confirmation: I say science is through a cause — supplying: the proximate and proper cause of the known thing, not through the most remote and universal cause, such as the first cause. Whether perfect science everywhere requires knowledge of all causes was touched upon above in Article X, and will be examined by design in natural philosophy.

Second objection: God possesses all science, which is free from all discursive reasoning, as I showed at length in the *Tract. de scientia Dei disp. I*. Therefore it is not necessary that science taken generally be produced through syllogistic discourse, as expressed in the aforesaid definition of science. Granting the antecedent, I say that created science alone involves discursive reasoning and carries with it imperfection, which is far from God, as I showed at length in that place.

Third objection: sometimes science is had of a contingent object — as of the eclipse of the moon, which is contingent — and of a corruptible and mutable object, as of physical things. Therefore it is wrongly asserted that science always has a necessary, incorruptible, and immutable object. I respond with Scotus (*ante §. Unde*): although the eclipse can be otherwise in itself, yet with respect to its cause it cannot be otherwise — for once the earth is interposed between the sun and the moon, the eclipse of the moon is necessarily obtained. As for the other point that is adduced: I say that science is not of an incomplex object but of a complex one — or of a conclusion — between whose subject and predicate there intervenes a necessary, eternal, and incorruptible relation, as the Doctor (*locis præcitatis*) says, and as I sufficiently declared in the first book (*quæst. II**, artic.* II*)*.

Article III. Whether Evidentiality Belongs to the Essence of Science.

Certain authors — such as Cano (*lib. XII de locis cap. II**)* and Mastrius (*cap. X primi Post. quest. III**, *conc.* I**)* — deny that evidentiality belongs to the essence of science. Scotus, however (*quæst. III principali, and IV coll. prol. §. Sed aliud; and III distinct. XXIV**, *quæst. vn. §. Ad quæst. sub D.*), Ruuius (*Tract. II de habitu scientiæ*), and the Coimbrans (*cap. XVI, quæstione prima, articulo tertio*)* affirm that evidentiality enters into the essence of science.

Note, from the Seraphic Bonet (*3. distinct. XXVI**, *quæst.* IV**), that certitude is described as the firm adhesion of the intellect to some object without fear. This is twofold: apparent and true. Apparent certitude is when the intellect, on account of some probable reason and through the efficacious application of the will, tenaciously adheres to some object — with reference to which Aristotle (*7. Eth. cap. III*)* says: "Some people cling as firmly to their false opinions or errors as others cling to the sciences." True certitude is that by which the intellect, on account of a solid and firm cause of the thing or an infallible authority, adheres to some object — as the philosopher firmly assents to: "man is risible, because he is rational"; or to: "the day of judgment will come, because Christ the Lord testifies it." The necessity of a proposition is that by which the proposition is true in such a way that it cannot be false, on account of the indissoluble nexus found between its extremes. Evidentiality, moreover, beyond firm adhesion, adds the manifestation of truth. For it is called evidentiality — that is, clear vision of the thing — which principles possess absolutely and of themselves, while science possesses it by participation in principles. Furthermore, evidentiality is divided into evidentiality of the object, which is the clear manifestation of the object to a cognizing power; and evidentiality of cognition, which is the clear manifestation of the knowledge attaining the object.

The assertion is: evidentiality belongs to the essence of science. So Scotus (*præcitatus*). First proof: from the definition of science, which is certain and evident knowledge, etc. What enters into the definition of something, especially in the direct line, belongs to its essence. Therefore, since evidentiality is included directly in the definition of science, it is clearly shown to belong to the quiddity of science. Second: what is the essential principle distinguishing something from other things is its essential constitutive principle, as I explained in the *Epitome* (*lib. I**, *quæst.* III**, *artic.* V**, *numero* X**)* and in the *Tract. de Deo Trino disp. ult.* Now evidentiality is the principle distinguishing science from faith, which is non-evident and obscure. Therefore evidentiality is the essential constitutive principle of science. Third: the principles that are the causes of science are essentially self-evident from their terms, as is clear from what was said. Therefore science is essentially evident. The consequence is deduced because if the cause is evident, its effect is likewise evident — indeed, effects are more evident to us than their causes, for through them we are led to the evident knowledge of causes. Therefore science essentially includes evidentiality.

First objection: subalternated science is true and proper science, yet it is not evident — since it can exist without the subalternating science from which it derives its evidentiality. Therefore evidentiality does not belong to the intrinsic nature of science.

I respond: subalternated science is science only insofar as he who has it can possess evidentiality of the principles that are handed down in the subalternating science. If he is unable to resolve these but only relies on someone's testimony, he will not be truly scientific, nor will his habit be properly called science — as I shall show below.

Second objection: our theology is truly science, even though it is non-evident and proceeds from the principles of the Catholic faith, which are non-evident. Therefore evidentiality does not pertain to the essential nature of science.

I respond by denying that our theology is properly and strictly science — what our authors call *de primo* of the *Posterior Analytics* — as I pursued at length in *Tract. I summæ Theologicæ*, and as Scotus does in *prol. quæst. IV*. It would now remain to treat of the unity of science. But since this can conveniently be understood from what was said about the unity of Logic (*lib. I**, *quæst.* VII**, *art.* IV**)*, I judge it should be passed over here.

Article IV. Whether the Division of Science into Practical and Speculative Is Essential.

Godfrey of Fontaines, the Nominalists, and not a few Thomists — cited by Faber (*quæst. IV**, *prol. disp.* IX**, *cap.* VI**)* — hold that the partition of science into practical and speculative is accidental, such that one and the same science can be simultaneously practical and speculative. Some assert this of theology, medicine, and logic — as certain authors whom Suárez (*disp. XLIV Met. Sect. XIII**, *numero* LIV**)* enumerates and defends, and which Ferchius (*1. vest. IX**)* vigorously champions. To these Scotus and with him all the Scotists oppose themselves (*quæst. IV Prol. §. Ad II quæst. E.E.*), together with the Complutenses, Diego, (*disp. I**, *quæst.* VI**)*, and many others, who hold that the aforesaid division is essential and quidditative — given, that is, through essential and quidditative differences. For the clarification and resolution of this difficulty:

We must recall and reconsider what I treated at length in (*lib. I**, *quæst.* II**)* and in *Tract. I summæ Theologicæ*. Above all in this place we note from the Doctor — both in the *quæst. præcit.* and in (*dist. XXVIII**, *quæst. vn. primi, §. Quamvis*)* — that the practical habit is used in two ways: either for the twofold aptitudinal respect of natural priority and conformity, or for the intrinsic nature of the habit itself, which is the foundation of that twofold respect. And the speculative can likewise be taken in two ways: either for the absence of that twofold respect just named, or for the intrinsic and essential constitutive nature of speculative

science, from which the negation of that twofold respect follows and arises as its passion. Accordingly, speculative science lacks the aforesaid twofold respect of natural priority and conformity; whereas practical science possesses it and is called practical by denomination from praxis, which taken most properly is an act of the will naturally posterior to the act of the intellect, to which it must conform — as I explained at length in the passage cited.

First Assertion: if "practical" is taken for the twofold respect just described, and "speculative" for the absence of both of the said respects, the aforesaid division of science is not essential. This is derived from the Doctor (*in prol. quæst. citata*, §. *Ex hoc D.*). First proof: of different genera not placed subalternately there are different differences, by the pre-predicamental rule. But science belongs to the genus of quality, as is clear from its series given in the *Epitome* (*lib. I**, quæst.* IV*, art.* VII*)*. The twofold respect mentioned, however, belongs to the genus of relation. Therefore "practical" and "speculative" are not essential differences of science. Second: no relative enters into the essence of an absolute, since they are opposed members of being. But science belongs to the genus of absolutes, being a quality — which is an absolute being — while "practical" taken in the first way is something relative, and "speculative" is the absence of the twofold relation just described. Therefore, with "practical" and "speculative" taken thus, such a partition of science is not quidditative. They may, however, be called disjunctive passions of science, just as even and odd are passions of number — as the Doctor (*ubi supra*) writes, followed by Mair (*ibidem*).

Second Assertion: "practical" and "speculative" taken in the second way are essential differences of science. So Scotus (*loco in antecedente assertionem memorato*, §. *Ad II quæst. E.E.*). First proof: from Aristotle (6. *Met. cap. I**; 6. *Eth. cap.* I**; 1. *Magnorum moralium cap.* XXXIII**)* who divides science into practical and speculative accordingly as it divides objects externally — which argues an intrinsic and essential distinction of the sciences, as two of our younger authors argue (*disp. XII**, quæst.* V*, art.* III*)* against Vásquez (1. *p. disp. IX**). *Second: every subaltern genus is divided into essential differences, as is clear from body and living thing in the Tree of Porphyry. But science is a subaltern genus, as can be seen in the table of Quality that I adduced in the Epitome (loco citato). And no other essential differences appear for it besides the rationes of the speculable and the practicable. These rationes are therefore essential and quidditative differences. Moreover: what constitutes distinct species are essential differences. But the practical and speculative rationes constitute distinct species of science. Therefore they are its essential differences. The major is known from "rational" and "irrational," which constitute man and brute. The minor is equally at hand from natural philosophy and ethics, which are distinct species of science — one speculative, the other practical. From these considerations it is clearly gathered that there is no intermediate science through participation in the extremes — between practical and speculative — as Suárez (*præcitatus numero LI*)* holds together with some others. But not rightly — and he seems to be mistaken on many points. First he fails to notice that one species cannot participate the specific nature of another species,*

just as a stone cannot participate the specific nature of man. For although man and stone agree in the common nature of being and substance, they share in no way in the nature of stone and man respectively. Similarly, since speculative and practical are like differences with respect to science in common, or even like species of it, science is properly divided into practical and speculative — just as a genus is divided into its species, or rather into its differences. However this is put, it plainly follows that no science can be simultaneously practical and speculative — a point urged not lightly in (*lib.* I*, *quæst.** II*, *art.** V*, *dub.** II*, *assert.** II*). *All the more so since, even through Suárez (ibidem), that division into practical and speculative is simply sufficient; therefore no intermediate science through participation in both is to be admitted. Hence Aristotle, dividing science taken generally, sets forth only two members — practical and speculative. If a middle science were granted, that partition would plainly be defective and incomplete. Again, according to the same Suárez (num. XLIII)*, practical and speculative are essential differences that make one science essentially differ from another; but one and the same habit cannot participate two essential differences essentially distinct from each other — as I showed regarding rationality and irrationality with respect to man in the passage cited. Therefore no science is found that mediates between practical and speculative.*

One may say, with Suárez, that two sciences can agree in this: that both treat of an operable thing as such, while differing in that one treats adequately of an operable thing and the other does not adequately, but in a superior and more universal manner. Thus "practical" can be taken either as abstracting from adequate and inadequate — and so it is only a subaltern difference — or as defined and limited to the habit that is adequately practical, and so it is the ultimate difference; and the same is to be said proportionally of "speculative." Accordingly, those differences do not cause essential diversity except as they are ultimate, and in this way they are never conjoined in the same habit; but as they are subaltern, they can be conjoined, because the same thing can have subaltern differences, and accordingly the same habit can be simultaneously practical and speculative.

Against this: every science is ordered toward speculation or toward praxis. For the end of the speculative is the contemplation of truth, and of the practical, operation — (*2. Met. cap. III**). *And although in practical science there are some principles that seem to be speculative, in reality they are not speculative but practical, because they tend to praxis mediately or immediately, formally or virtually. Hence the whole science is practical. And what Suárez further subjoins — that "practical" prescribes from the habit whether adequately or inadequately practical or speculative — is false. For either that is the primary genus in the nature of the practical or speculative, or it is not. If the first: then it is neither practical nor speculative formally, because it abstracts from both — just as being precisely taken is neither finite nor infinite, neither created nor uncreated. But it is impossible for any science to be constituted under the genus of practical and speculative while being practical and speculative simultaneously — just as it is impossible*

for a created being to be also uncreated, since it is contained under being in common. Furthermore, it is false to assert that "practical" — insofar as it includes an essential difference distinct from "speculative" — is an ultimate difference, because under one genus of formally practical or speculative science several species are comprehended, as is clear from the Doctor (3. distinct. XXXIV, quest. I*). Moreover, the inadequate notion of a thing does not constitute a subaltern genus. For every genus — whether subaltern or infimal — has its own adequate notion according to its being: as body, which is a genus, is adequate in the notion of body. Therefore that notion of an adequate or inadequate habit is irrelevant to whether a habit is simultaneously practical and speculative. Furthermore, two contradictories cannot simultaneously belong to one and the same thing. But practical and speculative appear to be two contradictories: for the speculative does not extend to operation, while the practical does extend to operation — as is clear from (3. anima cap. X; 2. Met. passu præalleg.)*.*

One may say: that is true of a habit that is adequately practical or adequately speculative — but not of a habit that is inadequately practical and inadequately speculative in different respects and under different considerations. Against this: whatever that habit may be, either it is ordered toward operation or it is not. If the first, it is simply practical. If the second, it is formally speculative. Therefore no intermediate habit intervenes between the two — as the Doctor (*in prol. citato*, §. *Quarta via sub M.*) concludes — whether through participation in the extremes, as I have proved up to this point, or through negation of the extremes, as Ferchius (*vestig. IX**, num.* XXVII*)* tenaciously maintains — against whom the undivided Scotists vigorously argue. And indeed Aristotle frequently divides science into speculative and practical only — as in (6. *Eth. cap. I**; 2. Met. T.* II*; 6. eiusdem operis, cap.* I*)* and in other places. The reason is, from the same Philosopher (1. Met. cap. II*, T.* XXVII*), *that every science is either for its own sake or for the sake of an operation. Likewise from Scotus (in prol. citato), every scientific habit either extends to praxis or does not extend to praxis. I add, from (3. anima T. XLIX; 6. Eth. II*)**, that every intellect is either practical or speculative. There is therefore found no middle through negation of the extremes between practical and speculative.

Nor should you be troubled or frightened by the objection of Ferchius based on Aristotle's frequent use of the tripartite division of science into speculative, active, and productive (8. *Top. cap. I*; 6. Met. I; 11. eiusdem operis cap.I). *For even if "practical" taken in the strictest sense, among Aristotle and all the Greeks — as appears from lexicæ — is equivalent to "active," and even though the passages of the Philosopher adduced by Ferchius (ubi supra) show this, and from which no Scotist departs in accepting the definition of praxis taken most properly — which, from what was said, is an operation of the will — nevertheless it cannot be denied that "practical" is also used for an operation that abstracts from active and productive. I produce the text of Aristotle (which Ferchius (num. XII, cap.II) greatly desires in his work ridiculing Vásquez (disp. VIII, cap.V), who for a text of the Philosopher adduces the testimony of Gregory (quæst. V prol.)). From (Met. VI, 1): αἱ δὲ πράξεις δὲ αἱ γενέσεις πάσαι, περὶ τὸ κατέκαστόν εἰσιν — where Fonseca*

translates: "actions and all processes of generation are concerned with singulars." Scotus and his disciples read: "actions are of singulars." The Thomists read: "actions are of individual supposita." It is clear there that praxis abstracts from action and production, since among singulars some bring forth action and others production. And a little further on, the same Aristotle calls those who work with their hands "practical men" (πρακτικούς). It is therefore clear that even in the usage of the leader of the Peripatetics the name "practical" extends to both active and productive. And rightly so, since this can be derived from its notion. I add from (2. Met. cap. I, T. III*): "the end of the contemplative is truth, πρακτικῆς δ' ἔργον" — that is, "but of the practical, operation." And shortly after he adds: "if practical men consider." In Greek this reads πρακτικοί. Nor does there seem to be a stronger reason for "speculative," which is predicated of all speculative sciences, than for "practical," which must likewise be common to practical sciences — into which Ferchius (cap. IV, ante num.*XVII) seems inadvertently to fall. Moreover, in (vestig. II, num.XIX) he observes from (7. Pol. I) and other places that speculation is called action and operation — or praxis — and he calls speculative men "active men." If this is conceded to Ferchius himself, why will it not be permissible for us, from the same Stagirite cited, to call the active and productive sciences practical? Again, the same author (cap. III*, vestig.* IX*, num.* XI*)* plainly admits that names are to be used according to the usage of Aristotle and other distinguished men. Since, therefore, Aristotle and commonly other philosophers employed the names just adduced, those who use the same words in the Peripatetic school are not to be blamed. Furthermore, although action taken strictly is not production (6. Eth. IV*)* — for action is πράξις in Greek and production isποίησις — nevertheless the Philosopher sometimes conflates both terms and speaks of them very ambiguously, as Suárez (disp. XLIV Met. sect. XIII*, num.* XXVIII*)* observes. Hence the custom has prevailed among all that "practical" comprehends both active and productive, and is distributed among them — just as "operation" is common to action and production and is distributed among them, as Tartaretus notes (6. Eth. quest. II*). Moreover, Diogenes (in vita Aristotelis) reports that there is a twofold branch of philosophy: one concerned with acts, called practical (πρακτικόν); the other consisting in understanding and speculation, called theoretical (θεωρητικήν). Again, "dialectic" is used for the Topics and "logic" for the Analytics, yet the common usage of recent philosophers aptly employs both names for the whole doctrine of reasoning — as I clearly showed in (lib. I, q.* I*). Moreover, Aristotle — in the chapter on quality — makes "disposition" common to habit and to disposition differing from habit itself; and in (3. Phys. cap. II, T.* VI*)* he defines motion, which is the genus of continuous mutation and motion, and "motion" absolutely is taken for continuous motion itself, especially local motion — as I noted there. There is therefore no such scruple about the acceptance of a word that "practical" cannot be adapted to both active and productive. All the more so since, as Scotus warns (3. distinct. VI*, quæst.* I*, §. Concedo sub D.), from Augustine (5. Trin. cap. VII; 1. Retract. cap.* XV*): "when the matter is clear, no violence need be done to the name." The same in (2. contra Cresconium cap. II): "when the matter is clear, there is no need to labor over the name." Cicero, cited by Augustine (lib. I*

contra dictum Crescon. cap. XI; 5. Civit. cap. V*), supports this: "A verbal controversy has long been tormenting those Greeks who are more desirous of contention than of truth." Finally Bartolus warns (in lib. de nomine, §. Plurimum): "In questions of name, common usage makes truth." For this reason the Doctor (1. dist. VIII, quæst.* I*)* rightly calls an objection about a name "childish."*

First objection: just as affirmation and negation are related to each other, so are speculative and practical; but negation and affirmation are not essential differences of science. The parity of the major is conceded: for "practical" affirms the twofold respect already explained in the being of science, while "speculative" denies that twofold respect.

I respond: this argument holds of "practical" and "speculative" taken in the first way, but not of them taken in the second way. This can be clarified by the division of the proposition into affirmative and negative, as well as by the differences "rational" and "irrational" — the former of which carries affirmation, the latter negation. For under the name of negation, a positive and real entity is understood, for which the negation is substituted.

Second objection: "extending to praxis" and "not extending to praxis" are contradictories, as I argued above — one negating the other — and therefore they cannot be opposed real positive differences. But practical science extends to praxis, and speculative science does not extend to praxis. Therefore practical and speculative are not essential differences of science.

I distinguish the major: if "not extending to praxis" is taken for the pure negation of extension to operation — I concede; but if it is taken, as it is taken in our matter, for a positive entity signified by the negation — as I was explaining in the solution of the preceding objection — I deny.

Third objection: practical and speculative are accidental differences of the intellect. For the same intellect is simultaneously practical and speculative through the practical and speculative habits received in it. Therefore likewise practical and speculative are accidental differences of science.

I concede the antecedent and deny the consequence. The reason for the disparity is that the intellect is the subject of inherence of all sciences, and therefore the speculative and practicable rationes are accidental to it. But since science is a subaltern genus of quality, it obtains the speculative and practicable rationes as its essential differences into which it is divided.

Article V. Whether Science Is Called Practical or Speculative from Its End or from Its Object.

In the present discussion, no doubt exists about the intrinsic and formal being of practical or speculative science; for it is held as established among all that science is practical or speculative through its own proper, intrinsic, and

quidditative speculative or practicable ratio — as Scotus teaches (*quæstione quarta, prol. articulo quarto, §. Contra istud G.G.*). The question concerns the extrinsic and effective being — namely, from what science is primarily made practical or speculative: from its end or from its object? On this point Godfrey (*quol. X*, quæst.* XI**)* asserts that act and habit are practical from the object, but the intellect from the end. Henry (*quol. VIII*, quæst.* I**), Gregory (*in Prol. quest. V, art.* III**)*, and others hold that act, habit, and intellect are practical from the end toward which they extend — which is praxis itself. But Scotus (*quæst. IV prol.*), Faber (*ibidem*), Vigerius, and other Scotists in the same place derive these differences of practical or speculative habit from the object, and of the intellect from the act and habit — practical or speculative — received in it.

First note: science is generated from the intellect and the object, as I wrote in the book *de anima* and in *Tract. de cognoscibilitate Dei disp. II*. For these are two partial causes constituting and making up one total cause — though one is more principal than the other, namely the intellect, which, being a universal cause, does not specify the science but rather the object of which the science is. This is clear from God and the sun, which, being universal causes, do not specify the things they produce; rather, specification comes from an inferior and particular cause cooperating with universal causes toward a common effect — as I showed at length in the book *de causis quæst. III*. Accordingly, the object concurs particularly in producing science, and science is denominated and specified from it — so that science of a natural body is called natural science, and science of God is called divine science. I further observe that the discussion here concerns the formal object, not the material object — around which several sciences labor — as Algazel (*lib. I*, cap.* I**)* says, and as I noted in (*lib. I*, quæst.* III*, artic.* I**)*.

Second note: from (2. T. XXXV *de anima*), the end is twofold: the end *for which* or *on account of which* something is done, and the end *to which* or *through which by means of which* something is done. The first is the object attained through the operation — as God, whom the blessed attain through vision and fruition. The second is the operation by which the object is attained — as vision and fruition, by which the blessed see and enjoy God. The end is also customarily divided into the end of the science — toward which the science by its own nature tends, as the end of metaphysics is the speculation of being universally taken — and the end of the learner, which is the goal he sets for himself who learns a given science, such as honor, profit, or something else. Some authors, whom Suárez (*ubi supra num. XXXII**)* cites, hold that both ends are necessary for the notion of a practical habit, but incorrectly — since, as Ockham (*quæst. IV*, prol. art.* II**), Gabriel (*ibidem, quest. XI*), and Gregory (*quæst. V**)* argue, in this way the practical and speculative would in science be a merely extrinsic denomination coming from the will of the knower, and so by a mere change of intention on the part of the knower, the same habit would shift from practical to speculative and vice

versa. Note also that the end of science is a cause only insofar as it is loved and desired, for the sake of which the efficient cause is moved to act.

First Assertion: acts and habits are not practical by virtue of extension to praxis as to their end. First proof: if acts and habits were practical because of extension toward praxis as to their end, this would be either because of actual or aptitudinal extension. Not the first — otherwise an artisan who is not actually working would not have practical knowledge. Not the second either — because aptitude does not belong to one nature and is incompatible with another except because of something intrinsic in that nature; therefore it is not on account of aptitudinal extension that acts and habits are to be regarded as practical.

Second: if a habit is practical from its end, it would be so either from an end had in reality or from an end known and loved. Not the first, because the end in reality is the last and posterior to the habit, and what comes first does not derive its being from what is posterior. Not the second either — for whether or not the end is desired and loved, most people have practical knowledge of these propositions: "one must live chastely," "the neighbor is to be loved" — yet they neither wish to live chastely nor to love the neighbor. Moreover, someone can learn architecture and know it excellently, even if he has no wish to practice it — which is the end of architecture. Third: if a habit were practical from its end, moral philosophy would not be practical, since according to Aristotle the end of moral philosophy is not praxis but the speculation of abstract substances, in which the same Philosopher imagines man's happiness to consist. But it is held as certain by all that ethics is practical; and therefore science is not practical from its end.

Second Assertion: a habit is not practical from its own proper act as from its primary and originating cause. The Doctor implies this (*citato*, §. *Concedo G.*). Proof: an act is not practical from itself but from something else — namely, from the practical object, as is clear from what was said. What is not practical of itself cannot be the reason for another's being practical. Therefore the habit is not primarily practical through the act.

Third Assertion: habit and act are held to be practical from the object with which they are concerned. This follows from the two preceding assertions, and is explicitly held by the Doctor (*ubi supra*) and by Antonius Andreas (6. *Met. quæst.* I*). First proof: from (6. *Eth. cap. I*)* where Aristotle distinguishes the ratiocinative from the scientific with respect to a necessary and a contingent object; and from (3. *de anima T. LI*)* he assigns the practical object not as just any object but as what is doable and contingent; and from (1. *Magnorum Mor. cap. XXXIII*)*. Therefore according to Aristotle, science is practical per se from the object. Second: from what a science has the twofold respect of priority and conformity, it is practical from that; but practical science has that twofold respect from the object. Therefore it is practical from the object. The major is clear from what was said. The minor is at hand: practical science has the respect of priority not

only by reason of the naturally ordered powers — insofar as the intellect is naturally prior to the will, and praxis is the act elicited or commanded — but also from the object, which precedes practical knowledge just as a cause precedes its effect, and practical cognition precedes praxis just as a rule precedes its regulated. It likewise obtains the respect of conformity from the object, because the object is either the rectitude of praxis or something virtually including that rectitude. For this reason practical science is such that praxis can conform to it so as to be right — because practical science is of such an object.

Fourth Assertion: the intellect is called practical by extrinsic denomination from the practical acts and habits inherent in it. So Scotus (*citatus*, §. *Ad rationes sub E.E.*). This is easily shown: practical acts and habits reside in the intellect just as whiteness and other colors inhere in paper. Therefore just as paper is denominated white and colored through the colors received in it, so the intellect is called practical or speculative through the practical or speculative acts and habits inhering in it.

First objection: Aristotle (*1. Met. cap. I**; *2. Met. cap.* III**; *6. eiusdem operis*)* writes that the end of the speculative is truth and of the practical is operation. Confirmation from (*3. de anima T. XLIX**): *the speculative and practical intellect differ in end. And from (6. Eth. cap. IX)**: the good of the practical intellect is acknowledged to be its conformity to right appetite.

I respond with Scotus (*citato*, §. *Ad argum. II quæst. sub D.D.*), expounding Aristotle thus: if "end" is taken not in the sense of end but in the sense of object, I concede that the habit is practical or speculative from its end; but if it is taken in the sense of end, I deny that the habit is practical or speculative from the end — except manifestatively and *a posteriori*. Although speculative and practical sciences obtain different ends, yet these ends do not primarily distinguish the sciences themselves; the prior distinction of sciences must be sought with respect to objects. To the confirmation I say, with the same Doctor (§. *Ad rationes E.E.*), that the speculative and practical intellect do not employ themselves about the same formal object, nor is the speculative intellect made practical by any extension. For Aristotle posits three grades of intellect: the first is to consider only speculables; the second is to consider doables in the universal without a dictate about their pursuit or avoidance; the third is to grasp means in the particular for attaining or avoiding an end. The intellect existing in the second grade — in which it is imperfectly practical — extends itself to the third and becomes perfectly practical by dictating the pursuit or avoidance of the end; and so that extension is of an imperfectly practical intellect toward perfectly practical consideration. Even if the speculative intellect can become practical in the way I now explained, the same is not to be asserted of the habit, since practical and speculative, with respect to the intellect, are accidental differences; but with respect to the habit they are essential differences. As for the text from (*6. Eth.*): I say Aristotle there is speaking not of the end posited in reality but of

the end known — which is interchangeable with the operable object — or he is showing *a posteriori* the difference between the speculative and practical habit.

Second objection: science is not called practical from the object. Therefore it is so from the end. The consequence holds. The antecedent is proved: a practical and a speculative habit can be concerned with the same object. For medicine is divided into speculative and practical, both of which deal with the same object — namely, the healable body. Confirmation: practical principles are derived from the end posited in reality; therefore the habit is practical from the end.

I deny the antecedent. In response to its proof I say that medicine is absolutely and simply practical, even though comparatively and in a certain respect it can be called speculative — as I explained at length in (*lib.* I*, quæstione secunda, articulo quinto, dub.* II*, not.* III*)*. To the confirmation I say it holds of the end insofar as it has the character of an object — not of the end insofar as it has a character distinct from the object, as I noted above.

Third objection: the quidditative ratio is derived from the per se causes of a thing through which it has its being per se and essentially. But the per se end of practical knowledge is the per se cause of it. Therefore the quidditative ratio of practical knowledge is drawn from its per se end — which is operation or praxis. First confirmation: practical knowledge is that which conforms itself to right appetite, from (6. *Eth. cap.* II*)*; but right appetite is appetite of the end as intended and loved. Therefore the ratio of practical knowledge is taken from right appetite as from a rule. Second confirmation: a practical act is called morally good or evil; but goodness or malice belong primarily to the act from the circumstance of the end. Therefore the habit is practical from the end.

I respond by conceding the major and distinguishing the minor: concerning the end *quo* — I deny; concerning the end *qui* — I concede; for this causes practical knowledge and has the character of an object. To the first confirmation: I explain that locus — practical knowledge conforms to the appetite for things passively — I deny; actively — I concede; for it has the character of directing and ruling, not of being directed and ruled, as is clearly evident from what was said. To the second confirmation: I concede the major and deny the minor. For as Scotus (*allegatus sub E.E.*) says, an act is primarily good from its object and secondarily from its end — as to love God is simply good without other circumstances. Therefore the goodness of a moral act is not derived primarily from the end as end, except insofar as it coincides with the object — as remains sufficiently explained in the above.

Article VI. Whether the Tripartite Division of Science Is Legitimate.

Since, from Aristotle (1. *Post. T.* XLIII*; 3. *de anima T.* XXXVIII*; 1. *Magn. Mor. cap.* XXXIII*), *the division of sciences is derived with respect to things and objects, and their origin from the same Author is from sense — consequently, as many primary sciences*

acquired through the way of sense are to be enumerated as there are primary things and objects, as the Scotists carefully observe with Scotus (6. Met. q. I).*

The assertion is: the partition of speculative science into natural philosophy, mathematics, and metaphysics is fitting and sufficient. Aristotle (6. Met. cap. I*), Scotus (*ibidem*, and III dist. XXXIV, quæst. vn. §. Notandum D.)* hand this down. Proof: there are as many primary speculative sciences as there are primary speculable objects; but there are only three primary speculable objects; therefore there are only three primary speculative sciences as enumerated above. The major is clear from the assertion of Aristotle cited at the beginning of this article. The minor is shown: the first speculable thing that presents itself to us is being — according to Avicenna (1. cap. V*)*: "being and thing are the first things imprinted on us" — and of being, together with the other transcendental predicates and the common quiddities of things, there is metaphysics. Being is most immediately followed by substance, which is divided into incorporeal and corporeal. Because incorporeal substance is known by us only with respect to common predicates, a particular and distinct science of it distinct from others is not generated in us; rather, its consideration also belongs to metaphysics as the general and universal science. Corporeal substance, however, can be considered in two ways: either insofar as it is affected by quantity — and of this mathematics is constituted, as Scotus (6. Met. citato, §. *Sed hac ratio*) writes — or insofar as it is the principle of motion — and of this there is natural philosophy. Therefore, since no other primary speculable object remains distinct from those three just mentioned of which another science might be had, it is clearly shown that the aforesaid distribution of science is legitimate and sufficient.

First objection: beyond the three theoretical objects just enumerated there is another speculable object — namely, the mode of knowing, which from what was said in (*lib. I**, quæst.* III*)* is the object of logic, which I counted among the speculative sciences (*ibidem*, quæst. II*, dub.* I*, art.* V*). *The aforesaid division of speculative science is therefore defective and illegitimate. Alexander (1. Priorum), Philoponus (ibid.), Themistius (1. Post. c. II), and the Parisian masters (1. Phys. quæst. II)** respond that this division was handed down concerning real speculative science, not rational science such as logic; or concerning principal speculative science, not instrumental science such as logic.

Second objection: of corporeal substance there is one contemplative science — namely natural philosophy. Therefore of incorporeal substance another speculative science is to be constituted, and accordingly there are at least four speculative sciences.

I respond: the reason has already been given by us why there is no special speculative science of incorporeal substance distinct from the three enumerated — namely, because of that threefold division discovered and assigned through the way and ministry of sense. By this way we cannot hunt down knowledge of

incorporeal substance, since its passions are hidden from us. Therefore a fourth speculative science of it is in no way conceded.

Third objection: being is adequately distributed into substance and accident. Therefore just as of corporeal substance there is one speculative science, so of corporeal and material accident another speculative science is to be posited.

Granting the antecedent, the second part of the consequence is to be denied. The reason is that science is of a conclusion — when, namely, a proper passion is demonstrated to inhere in a subject. But an accident — whether proper or common — cannot be such a subject. Therefore no speculative science of it is acquired that is distinct from the three related.

Article VII. Whether One Science Is Subalternated to Another.

That among sciences some are unrelated, having no relation, connection, or dependence on each other — as natural philosophy and metaphysics — and that some are subaltern or subordinated, with one depending on another, is distinctly and openly taught by Aristotle (*1. Post. cap. I**), Scotus (*in prol. utriusque operis, Oxoniens. quæst. IV principali, 5. later. Report. quæst. III; 3. dist.* XXIV*, quæst.* I**), and the interpreters of both in the same places.

First note: subalternation, by the etymology of the name, means nothing other than the placing of one science under another — which expresses the subordination, containment, and dependence of one science on another with respect to certitude and evidentiality, as the Doctor hints (*4. distinct. XLIV*, quæst.* III*, §. Hic dicitur D.*). Bonet (*2. Met. cap. VI**) and Tartaretus (*1. Post. quæst. V*, scibili* IV**) assert many modes in which sciences can be subalternated to each other. The Coimbrans (*eo in loco, quæst. VII*, art.* I**), Fonseca (*4. Met. cap. I, quæst.* I**), and Suárez (*disf. II Met. Sect. V, n.* XLVII**) mention three. The first is effected by reason of end: in this way the science whose end is under the end of another is said to be subalternated to it, the latter commanding the former to minister to it in operation whatever is opportune and necessary for the attainment of the end — as in (*1. Eth. cap. I**) the art of bridle-making is subalternated to horsemanship, horsemanship to military science, and military science to politics. The second is by reason of principles: when the principles of the inferior are proved through those of the superior — as is clear from surgery and geometry. The third is by reason of object: in this way that science is subalternated to another whose subject is comprehended under the subject of the other and essentially depends on it — as music and arithmetic. This last is the true and proper subalternation of sciences, of which Scotus (*cit., and III distinct. XXIV*, quæst. vn. §. Quæstio ante A., and §. Ad* I ante J.*) treats.

Second note: for the genuine subalternation of sciences, three conditions are required — gathered from Aristotle (*cit.*) as noted by Oviedo (*contr. I*, puncto* IV**). *The first is that the object of the subalternating and the subalternated science be in some way the same. For since sciences are specified by their objects, and these sciences are*

subordinated to each other, it is necessary that the object of the subalternated be contained under the object of the subalternating, so that both enjoy the same essential object, differing only accidentally. For they are distinct sciences with distinct conclusions, since the principles of the subalternated are conclusions of the subalternating. Hence Scotus (*in prol. alleg. §. Sed quid*) produces that common saying, defining: "where the subalternating ends, the subalternated begins." The second condition is that the object of the subalternated be contracted through some accidental difference — as a line is the subject of geometry, while a visual line is the subject of perspective. Likewise, number is the subject of arithmetic, while sonorous number is the subject of music — as Scotus expresses (*1. Prior. q. II, q. Quantum ad* III**)* and as is gathered from Aristotle (*ubi supra*), who affirms that the subject of the subalternated is other than the subject of the subalternating. For I noted in (*lib. II*, quæst. de differentia*)* that the term "other" (*alterum*) designates accidental difference, while "another" (*aliud*) designates essential difference. All the more so, since if the subject of one subaltern science differed essentially from the subject of another, there would be no difference between subaltern and unrelated sciences. For since the essential distinction of sciences is derived from objects, if their objects differed essentially — just as the objects of unrelated sciences — these would not differ from those. The third condition is that the subalternated derive its principles from the subalternating — as some explain of medicine, which they hold to be subalternated to natural philosophy, because it takes its principles from natural philosophy — for instance, that hot things are cured by cold. This is a true proposition of medical discipline, relying on that assertion drawn from natural philosophy: "contraries drive each other out from the same subject." For since there is between these sciences the dependence that I asserted above to be required for subalternation, it follows that the principles of the subalternated are conclusions of the subalternating — and where the subalternating ends, the subalternated begins. This is the teaching of Aristotle (*lib. de sensu et sensili; Met. c. I**)*. Nor does anyone properly understand the subalternated unless he knows how to resolve the conclusions of the subalternated into the immediate or mediate principles of the subalternating — for all the certitude and evidentiality of conclusions is derived from their principles. Hence Aristotle adds that principles are truer than conclusions, because the latter obtain their truth on account of the former. Whoever does not possess the subalternating cannot resolve the conclusions into their principles — from which those conclusions derive their certitude and evidentiality.

The assertion is: some sciences are subalternated to each other. So Aristotle (*1. Post. c. XI**)* and Scotus — both in (*1. Prior. q. II*, §. Quantum ad* III**)* and in (*q. IV prol. and S. lat.*). Proof: those sciences are subaltern which possess all the conditions required for true and genuine subalternation of sciences; and some sciences are of this kind. Therefore subaltern sciences exist. The major is known. The minor is at hand concerning arithmetic and music, and concerning geometry and perspective — to which the conditions described in the second

note are adapted, as was explained there. Furthermore, science taken generally is divided into unrelated and subaltern — from Aristotle (*passu alleg.*) — because some sciences do not depend essentially on others, as natural philosophy, mathematics, and metaphysics; while some essentially depend on each other, as I just declared. Add what Bonet, Suárez, and others (*præcit.*) argue — that metaphysics does not subalternate the other sciences to itself — as I shall make plain in (*l. I Met. q. II*, a.* II**)*: both because the other sciences are acquired without metaphysics, as is clear from the practice of teaching and learning; and because the subject of the other disciplines is not contracted through an accidental difference, and therefore does not form one thing per accidens with being — the subject of metaphysics. And the other doctrines obtain their own proper principles independently of the principles of metaphysics, and therefore are not subordinated to or subalternated by it.

First objection: from (*6. Met. T. IV**)*: of being per accidens there is no science; but the object of the subalternated is being per accidens — namely, contracted through an accidental difference — as is clear from the second note. Therefore no subalternation of sciences exists.

I distinguish the major: concerning being per accidens that is casual and fortuitous — I concede; concerning being per accidens that designates a subject with an accident inhering in it, whether expressed by one or more names — I deny. So from Scotus (*6. Met.*) respond Orbellus (*ibid. c. I**)* and Tartaretus (*in loco*). The Coimbraans (*in proæm. Phys. q. II*, l.* IV*, ad* III**)* and the Doctor (*in Report. q. VII prologi*) sense the same. The reason is that subaltern sciences participate the same essential and formal object, merely in the subject; to the subalternated is added an accidental difference through which the latter accidentally differs from the former — as to the line, which is the subject of geometry, is added visibility, which is the accidental difference considered by perspective. For perspective proves many things that do not belong to the line precisely, and shows many things not through visibility alone but through both rationes — that is, the visual line. Hence the subalternated science is of being per accidens because its nature so demands, possessing an object that differs only accidentally from the object of the subalternating. This therefore seems to be its proper character — just as it belongs to quantity to be predicated denominatively of its species, as I noted in the question on quantity. And the motion of the heavens is regular, except in the epicycle circles, as I noted in (*lib. de cælo quæst. I*, art.* X**). Similarly, of second intentions — which are predicated of first intentions, and of which logic is the proper science — as the Doctor teaches (*4. d. I, q.* II**). Moreover, the subalternated is not reckoned a science unless it is caused by the object of the subalternating. Hence the perspective student is not scientifically knowing unless he is a geometer — as Scotus infers (*3. Report. d. XXIV, §. Ad* II**)*. Finally, although the object of the subalternated is one per accidens in entity, it is nevertheless one per se in order — which can be defined, demonstrated, and known.

Second objection: Aristotle (*1. Post. c. VII**, *T.* XX**)* writes that the musician and the perspectival scientist are concerned with the same demonstrations that the arithmetician and geometer pursue. Therefore there is no subalternation of distinct sciences; and afterward the same Philosopher adds this difference — that the subalternating demonstrates *a priori* and the subalternated *a posteriori* — and calls them univocal, others calling them related and cognate.

I respond: the cited text is wrongly adduced by some. For Aristotle there only asserts that every science proceeds from its own proper principles, and that there is no passage from genus to genus in them — except in subalterns, on account of their kinship and mutual dependence. To the other point subjoined: I say the Philosopher there only means that the subalternating proceeds from immediate principles and the subalternated from mediate principles only — because the conclusions of the former are the principles of the latter. To the final point: I say that the Stagirite calls them "univocal" on account of the subordination and connection found between them.

Article VIII. Whether the Subalternated Is Properly a Science.

St. Thomas (*in lib. Boëtij de Trin. q. II**, *a.* III**, *ad* V**; *1. p. q.* I**, *art.* II**), Cajetan, and others of the same school (*ibid.*) affirm that the principles of the subalternated are held on human faith alone — insofar as he who has subalternated science believes them to be certain and true from what has been demonstrated by the subalternating science. Scotus, however — (*q. IV prol. §. Ad II q.*, in *Report. q. III*, and in *both works 3. d. XXIV*, *q. unica*)* — and his disciples (*ibid.*), together with Bañez (*1. p. q. I**, *art.* II**, *dub.* II**)* who subscribes to them, teach that such principles are known by subalternated science with certain and evident cognition, such that he who has the subalternated science is not truly scientific unless he fully knows their evidentiality.

First Assertion: the subalternated is truly and properly science, distinct from the subalternating. Scotus (*locis prænominatis*) defends this. First proof: from Aristotle (*1. Post. c. X**)*, who, presupposing that true demonstrations are effected in the subalternated — through which true science is generated — only investigates the mode in which they are formed. Since, therefore, proper and distinct demonstrations generate proper and distinct science, it is clearly shown through Aristotle that the subalternated is properly science. Second: the subalternated is of conclusions properly known, distinct from the conclusions of the subalternating — as is clear from the saying I adduced in the preceding article: "where the subalternated begins, there the subalternating ends." Again, the object of each is scientific and in some way distinct — and one presupposes the other and depends on it — as was explained above. Therefore the subalternated is to be numbered among the sciences.

Second Assertion: the subalternated is not science unless it knows the principles of the subalternating and can acquire for itself the subalternating. So Scotus (*in*

Report. q. III prol., in the III just mentioned). First proof: from Aristotle (*1. Post. cap. II**), who writes that in order for someone to have science of any demonstrated conclusion, the principles must be self-evident to him from the terms and indemonstrable — or, if they are demonstrable, he must know how to reduce them to the indemonstrable. But he who does not know or cannot do this has neither demonstration nor science. The principles of the subalternated, however, are demonstrable through the subalternating science — being its conclusions. Therefore if he does not know or cannot reduce them, he will not be truly scientific, nor will the subalternated be truly science. Second: certitude and evidentiality are of the intrinsic nature of science, as was established above from Scotus (*3. Report. d. XXIV, q. vn. §. Dico**). Therefore, since the conclusion of which there is science derives its certitude and evidentiality from the principles, it follows that it is not properly science unless he has those principles as known and evident and can resolve them.

First objection: our theology is subalternated to the theology of the blessed, as St. Thomas (*1. p. q. I*, art.* II**)* asserts; yet we have no evidentiality of its principles, since we now see in an enigma (*1. Cor. XIII**)*. Therefore it is not necessary that for one possessing the subalternated, the principles of the subalternating be known and evident.

I deny the antecedent with Scotus (*q. III prol.*). The reason is that both theologies are about the same principles — with this difference, namely, that to the blessed the principles are evident, while to us they are obscure and enigmatic.

Second objection: the identity and diversity of sciences is derived from the identity and diversity of objects, as I have urged more than once above; but the object of the subalternated and the subalternating is essentially the same formal object, as is clear from the second note. Therefore subaltern sciences are not distinguished.

I concede the major. To the minor I say that although the essential object of both is the same, nevertheless the object of the subalternated differs accidentally from the object of the subalternating — which is sufficient to distinguish subaltern and subordinated sciences.

Article IX. Whether Science Can Be Newly Acquired.

Plato (*10. de Rep.*) and others — among whom Origen (*1. Periarchon. c. VII**)* does not seem far distant, and to whom Avicenna and Averroes (*3. de anima*) appear not dissimilar — suppose that rational souls were created from the beginning of the world, adorned with all sciences; and therefore that in our age no new science is generated in them, but that all science is the recollection of things they already possessed before the souls were united to bodies — through union with the bodies, however, they forgot all of these things and were as it were clouded over and buried. The opposite is defended by Aristotle (*1. Post. T. IV**; *2. eiusdem operis, c. ult.*; *1. Met. T.* IV**), Scotus (*1. Post. q. I, 2., 3.*; *Quol.* XIII*, §.* Nunc ante S.; *3. d.* XXIV*, q. vn. §. Contra infra B.*; *4. d.* XXXIV*, q.* III*, §. Hic*

paulò ante G.), *Gadius* (*Quol. alleg. fol. CXXXVI*), *Lychetus*, *Tartaretus* (*ibid.*), and all other philosophers — both pagan and orthodox — especially Augustine (12. *Trin. cap. XI*)*.

The assertion is: science is newly acquired by us, and no knowledge of things is innate in us. So Scotus (*locis prænominatis*). This can be shown from sacred Scripture: (*Gen. III*)*: "I have learned by experience." (*Rom. XVI*): "The doctrine which you have learned." (1 *Cor. XIV*): "that all may speak." And (*Joan. VII*): the Jews, hearing Christ the Lord teaching in the Temple — knowing that he had not attended the schools — marveled, saying: "How does this man know letters, since he has not learned?" But if knowledge of things were innate with us, there would be no need to teach or to learn — since we would already possess it. Again, in the book of Genesis the first inventors of the arts and sciences are narrated; they would be wrongly called authors and inventors if all those things had existed from the beginning of the world. Second: if sciences were created together with our souls, they would not be hidden from us — as the Stagirite argues at the end of the second book of the *Posterior Analytics*. For it is impossible that one who knows should be unaware that he knows, since science is clear and evident knowledge — just as it is impossible for someone who has light present and an object properly approximated, with every obstacle removed, not to see. But we experience in ourselves no science naturally instilled in us. On the contrary, whatever we have, we acquire by labor, sweat, and study. Third: no form is harmed through union with matter, since it naturally tends toward it. But the rational soul is the form of the body, as the Lateran Council (*ad Leonem decimum*) ordains. Therefore the rational soul is not impeded by the body from exercising the acts of science; and accordingly, if it had science from nature, it would elicit its acts, and man would need neither teacher nor study — which is contrary to experience. Therefore, since it is verified by experience that all science in us is generated either through invention or through teaching — whose first guides are the senses, perceptive of singulars, from whose knowledge experience arises, and from experience science is generated — as Aristotle (2. *Post. in calce*; 1. *Met. c. I*)* plainly teaches — it is shown that science in us is not from recollection. All the more so because the Platonic foundation is false and erroneous. For orthodox faith teaches us that the rational soul is created by God at the very moment at which the human body is duly organized in the mother's womb — into which it is infused by God himself — so that from both man is constituted and composed; and at that moment it is like a clean tablet on which nothing is depicted, as the Peripatetics admit with their chief (3. *de anima XIV*)*. Therefore no scientific knowledge is naturally implanted in us, but whatever knowledge a man possesses, he acquires and obtains for himself through art and study.

First objection: either someone already knows the proposed thing or he is ignorant of it. If he knows it, there is no need to seek it further. If he is ignorant, he seeks it in vain — since he does not know what he is looking for; and even if it presents itself to him, he will not know that he has found it. Therefore no new science can be acquired by us. This dilemma of Meno is mentioned and refuted

by Aristotle (*1. Post. c. I**)* and by the Doctor (*ibid. q. II**), *and is touched upon by the same* (*4. d. XLV, q.* III*, §. De* II sub F.*).

I respond: granting the case, that person knows the thing confusedly and virtually — because he knows the principles, in which the conclusions are virtually included — but he does not know it distinctly and actually. Between ignorance and science there mediates confused cognition; and Plato, not acknowledging this, denies that science can be newly acquired. Aristotle, however, admitting it, grants that science is acquired by us anew — for whose attainment the judgment of the intellect is needed, so that from evidently known principles, from knowledge of the terms, scientific conclusions are deduced through appropriate application of the premises to those conclusions, as Scotus (*1. Post. in fine q. III**)* rightly observes against Plato.

Second objection: if any scientific knowledge of a thing could be newly obtained or acquired by us, it would be acquired either through the intervention of the senses or through the work of a teacher — but neither can be effected. Therefore all science is had through recollection. The major is clear. The minor is shown for both parts. Not through the ministry of the senses, because the senses frequently err, and many things escape the senses of which we have science; nor through the industry of a teacher, since for understanding things — beyond the natural light of the intellect — intelligible species are required, which the teacher cannot transfer into and infuse into the intellect of the pupil — as the Platonists argue, as Scotus (*1. Post. q. II*, §. Ad q.*)* reports.

I respond: science is generated in us in both ways — and indeed in the first way, for whose acquisition it is sufficient if things are present in sense per se motivally or occasionally; and also in the second way. For the teacher proposes to the pupil axioms and self-evident principles, for the knowledge of which knowledge of the terms alone is required; then through external signs and sensible examples presented by the same teacher, the mind of the pupil is easily roused to know things, aided and taught — as the Doctor (*passu nuper citato*) hands down no less learnedly than eruditely.

Article X. Whether Science and Faith Can Simultaneously Exist in the Same Intellect Concerning the Same Object.

The common opinion of scholastics (*3. d. XXIV*, q. vn.*)* holds that subalternating and unrelated science can coexist in the same intellect about different objects. But concerning whether subalternating science can simultaneously coexist with faith about the same thing in one and the same intellect: St. Thomas (*1. p. q. I*, a.* II**), Cajetan, and others (*ibid.*) maintain it can — holding that our theology is a science subalternated to the theology of God and the blessed. Scotus, however — (*q. II mox alleg.*) — together with Ballester, Lychetus, and others (*ibid.*) deny that science — whether subalternating or subalternated — and faith about the same object can be compatible in the same intellect. As for whether our theology is

science or not, and whether it is subalternated to the theology of God and the blessed, see what I wrote at length in Tr. I summæ Theolog. disp. II, q. II*.**

First note: this question can be agitated both concerning divine and human faith. Faith taken universally is a firm and determined assent sustained by the testimony of one worthy of belief. "Assent" is placed as genus. "Firm and determined" is added to differentiate it from ambiguity, suspicion, and opinion. The remaining words are added on account of science, which is obtained through a proper and evident cause. Since, moreover, the testimony on which faith rests is twofold — namely divine and created — faith is accordingly posited as twofold: divine and created. Divine faith is described from (*Hebr. XI**): *"the substance of things hoped for, the evidence of things not seen."* This is subdivided into *infused — which is a habit infused in us by God concerning matters to be believed — and acquired — which is a habit acquired in us from hearing things to be believed, sustained by divine authority.* Created faith — whether angelic or human — is a certain assent to a thing had on the testimony of one worthy of belief. On this see Scotus (*Quol. XIV**) and Gadius (*eo in loco*).

Second note: every kind of faith rests on two principles: one is that the thing to be believed is stated by someone; the other is that the one who states it is truthful — as is clear from the description of faith given in the first note. Each of these, moreover, is either obscure — as when I know both from conjectures — or both are manifest — as when I hear a speaker and what he says is plain — or one is obscure and the other manifest — as when the thing to be believed is clear, but not the one testifying. The Doctor (*præcit.*) notes that acquired faith exceeds opinion, because faith firmly adheres to one part while opinion, even if it adheres to one part, does so with fear of the other. But faith is surpassed by science, because science is evident while faith is non-evident and enigmatic.

The assertion is: science and faith — both divine and human — concerning the same thing cannot simultaneously be in the same intellect. So the Doctor (*ubi sup.*). First proof: from the definition of faith handed down by the Apostle and recalled by me in the first note — which is "the evidence of things not seen"; but science is of things seen and evident, as is clear from (*1. Post. c. II**). *Either, therefore, things do not appear — and of these there is faith — or they appear, and of these there is science — as St. Gregory divinely concludes (hom. c. XX Joan.). And accordingly, science and faith cannot simultaneously hold in the same intellect about the same object. Add the saying of the same holy Doctor received by all: "Faith has no merit where human reason furnishes experience." If, therefore, there were in us science of the divine articles, we would be worthy of no merit. But having faith of those same things, we merit — indeed without faith it is impossible to please God. We are not those who know the mysteries of God but only those who believe; and accordingly science and faith do not tolerate each other simultaneously in the same intellect about the same object. Hurtado (disp. X de anima, sect. V, §.* LVII*) and Arriaga (ibid. disp. VI*, sect.* VI*, subf.* I*, n.* XCVII*) respond after Valentine (t. III*, disp.* I*, q.* I*, p.* IV*),*

distinguishing: through the same formal objective ratio — they concede — because the motive of faith is divine revelation, or human or angelic authority, which are obscure and non-evident; through a diverse formal objective ratio — they deny — because through the scientific motive the same thing can be clear and evident. Against this: first, these authors seem to overstep the limits of the proposed theme by asserting their position about the same material object with respect to diverse formal rationes — since in the present discussion, as Tartaretus and others (præcit.) note, the dispute concerns the proximate, not the remote object — the material object being of this kind — and also concerning the specific and numerical object, as Hurtado (cit. §. LXV) and Arriaga (subf. II*, n.* CVII*)* indicate. Above all because it is held as conceded by all that around the same material object several habits are concerned — as I explained in (l. I*, q.* III*, a.* I*). Then Hurtado (q. LIX)* asserts that actual science and actual faith cannot simultaneously exist. From his assertion I argue thus: actual faith and science come about through diverse media — as Hurtado himself (sup.) openly admits; for that reason science and faith can be composed. Either, therefore, that response and distinction are void, or Hurtado's assertion is false and self-contradictory. Nor does it help to say that actual faith and science involve a contradiction while habitual faith and science do not. For someone could easily respond in the doctrine of those recent authors that there is no incompatibility — since each would be had through diverse media. If, therefore, the diversity of media makes the simultaneous existence of habitual faith with science possible, so equally that of actual faith with science. And if Hurtado objects, saying that no one can persuade himself of two contradictories simultaneously — while through science he has an evident object and through faith a non-evident one, and evident and non-evident are contradictories — the same applies equally in both actual and habitual faith with science. Absolutely, therefore, it must be denied that faith and science can be composed together. Moreover, contradiction is negation and affirmation simultaneously of the same with respect to the same — as Hurtado admits (§. LXIII*)* from (4. Met. T. IX*)*. But someone in his view and that of others could present himself and say: there is no contradiction in the simultaneity of actual faith and science, because contradiction is not found with respect to diverse media — as I was just arguing.*

Second proof: the same thing cannot simultaneously be clear and obscure — as is clear from air, which is either luminous or shadowy. But through faith the object is rendered obscure, and through science clear — as the Doctor (alleg. ante §. Quæstio) confirms from the authority of the Apostle Paul (2. Cor. V): "for we walk by faith and not by sight." Therefore faith and science cannot simultaneously remain. The authors just named respond, distinguishing the major: through the same act — they concede; through a diverse act — they deny. For they say clarity and obscurity regard the act, not the intellect, which is capable of a clear and obscure act. Hence they add there is no parity with luminous and shadowy air, since obscurity designates the privation of clarity in the same act — not in the same intellect — and in this the disparity with darkness, which denotes the privation of light in the air, not in the light itself, is located.*

Against this: the same Hurtado (§. LIX) explicitly says that the intellect cannot simultaneously affirm or deny through one act, or through two, because it cannot persuade itself of two contradictories. Therefore even if there are two acts — which Hurtado himself concedes — contradiction is still present. For through faith he affirms that the object is obscure and non-evident; and through science he denies that the object is obscure and non-evident. For the same object to be simultaneously obscure and not obscure, clear and not clear, evident and not evident, involves open incompatibility — which the diversity of media or acts cannot remove. Furthermore: if the duality of acts removes contradiction concerning the same object in the same subject, then plainly assent and dissent about the same thing in the same intellect would simultaneously be possible — because through one act the intellect gives assent and through another act dissent about the same object. This Hurtado (*disp. VII de anima, sect. II*)* and Arriaga (*disp. VI*, sect.* VI*, n.* LXXXVII**)* deny. Again, the same will could will the same through an act of willing and simultaneously not will it through an act of not-willing — because these are distinct acts. Which the same Arriaga (*ubi sup.*) does not concede. Therefore, by the diversity of the acts of science and faith about the same object, the argument is not dissolved — especially because a clear and an obscure act are opposed, just as light and darkness. Therefore, just as light and darkness cannot simultaneously be received in the same air, so a clear and an obscure act cannot be in the same intellect — which is the subject of both — and in this lies the parity. Hence in heaven there is no act of faith on account of its obscurity, but there is indeed an act of science on account of its clarity: (1. Cor. XIII*): "then face to face." And (Apoc. I): "his face shines like the sun." For this reason Hurtado (*cit. §. LXXIII*)* concedes that the light of glory and habitual faith are incompatible ex natura rei.*

First objection: the same object can simultaneously be known by the same intellect through abstractive cognition — which is had through a species of an absent object — and through intuitive cognition — which is of a present object — as Scotus (2. d. III*, q.* IX*, §. Ad q. B.)* writes; and in the same place (q. VIII*)* he concedes morning and evening cognition in the blessed, and in (3. d. XIV*, q.* III*)* he posits infused and acquired and beatific science. But abstractive cognition is obscure and intuitive cognition is clear. Therefore there is no incompatibility in simultaneously having faith and science in the same subject and about the same subject. Confirmation: Thomas the Apostle simultaneously had faith and science concerning Christ the Lord — as is read at (Joan. XX*)*: "because you have seen me, Thomas, you have believed." Likewise, John the Evangelist saw Christ crucified — of which there is an article of faith. Therefore science and faith are not incompatible with each other in the same subject and about the same object.

I respond: although both types of knowledge can be in the same intellect, not simultaneously. The reason is that the same thing cannot simultaneously be present and absent, existing and non-existing, seen and not seen to the same

intellect. To the confirmation: I say with Scotus (3. d. XXIV*, q. vn. §. ad* I *ante M.*), from St. Gregory (*hom. in octava Paschatis*), that Thomas saw one thing and believed another. He saw the humanity and believed the divinity of Christ. Hence the same Apostle adds: "my Lord and my God." Similarly John the beloved and the others saw Christ as man suffering and believed him as God. Likewise, the Blessed Virgin, although she knew for certain that she had conceived a man without male seed, believed by faith that she had conceived the God-man. Thus those who saw Christ born, crucified, and risen did not have faith about these things but about other mysteries — and even if they had not seen those mysteries, they could by the habit of faith believe in them, as Scotus (*ubi supra*) learnedly infers. One may press further: St. Paul (2. Cor. XII*)* saw the divine essence, and about it had faith. For he did not lose the habit of faith through such a vision. Therefore faith and science can simultaneously coexist in the same intellect. It must be answered that the Apostle had faith concerning what he did not see — since such vision was passing and of an hour; for this reason it is probable that he did not see all that we believe, but saw some things and believed others. Therefore he retained the habit of faith concerning what he did not see.

Second objection: every person — whether learned or unlearned — is bound to believe that God exists. According to (*Hebr. XI**): "*he that comes to God must believe that he is.*" This is numbered among the articles of faith, as is clear from the Apostles', Nicene, and Athanasian Creeds. The unlearned person knows God only through faith; but the learned philosopher has not only faith but also science of the existence of God — as I showed in (*Met. I, 4., q. vn.; Tract. de Deo uno, disp.* I*, q.* I**)*. Therefore faith can simultaneously coexist with science in the same subject.

I respond: with the arrival of science, faith retreats — just as with the arrival of light, darkness departs. Therefore the philosopher who has science that God exists does not have faith about his existence, but about other articles — such as that God is one and triune, the restorer of the human race, and the like — which are supported only by divine revelation.

Third objection: Aristotle and other philosophers sometimes, after a demonstration that produces science, adduce authorities of ancient philosophers, which produce faith. Therefore it is possible for faith and science to simultaneously dwell in the same intellect. The illumined Doctor (3. d. XXIV*, q. vn. art.* VI*)* considers this argument seriously, saying: it was the custom of philosophers to instruct disciples through authorities and sayings of others, then through probable arguments, and lastly through demonstrations. Authorities produce faith, probable arguments produce opinion, and demonstrations produce science.

I respond: authorities following upon the demonstration of a knowable object produce nothing in one who has demonstration and science of the same object — as the Doctor (*in II cit. §. Ad I princip. M.*) affirms concerning the dialectical

middle term with respect to the analytical. But if testimonies precede the demonstration, they produce faith — and with the arrival of demonstration, faith is removed and science alone remains. But when something is demonstrated, the assertions of others are usually adduced not because they cause faith in the one demonstrating, but so that it may be plain that such doctrine is in agreement with others, and so that it may be shown that other authors preceded who championed such doctrine — and that Aristotle or another philosopher was not its primary inventor and author. Scotus adds (*1. d. II**, q.* *III**, §. *Ad illa ante C.*)* that things which can be demonstrated it is useful for the community to have handed down through authorities — both on account of the negligence of the commonwealth in seeking truth, and on account of the weakness of the intellect, and also on account of the errors of those who hunt by demonstration, who mingle many falsehoods with their truths, as Augustine (*18. ciuit. c. XLI**)* asserts. And since simple folk, leaning on such demonstrations, might doubt whom to assent to and stand with, therefore the safe way is the common, easy, and certain authority — which can neither deceive nor be deceived.

Fourth objection: the light of the sun and the light of the stars are found in the same part of a medium, even though the former is greater and the latter lesser — and together they constitute one light. Therefore likewise in the same intellect, authority and demonstration cause the same assent about the same object.

The parity is to be denied: because since those lights are qualities of the same species, they intensify each other; but the latter — authority and demonstration — are of a different species, being opposed habits, and therefore cannot coexist.

Article XI. Whether Science and Opinion About the Same Object Can Simultaneously Exist in the Same Intellect.

Although this difficulty is almost resolved from the preceding article, and the same number of opinions exists in the present as were related there, it is nonetheless pleasing to inquire specifically whether science and opinion can simultaneously persist in the same intellect. The Irrefragable Doctor (*3. P. q. LXXV**, n.* *III**)* and the Seraphic Doctor (*3. d. XXIV**, q.* *III**, art.* *I**)* — to whom Ruuionius, Richard, Mair, Basle, and most other ancient and recent scholastics adhere — affirm that, through diverse media — namely demonstrative and topical — both as regards habits and as regards acts, about the same object in the same intellect, science and opinion can simultaneously cohere. The opposite is defended by the Subtle Doctor (*3. d. XIV**, q. *vn.*), the *Angelic Doctor* (*1. Post. lect. XLIV*; *de veritate q.* XIV**, a.* *IX**, ad* *VI**)*, and the disciples of both — ancient and modern — who deny that, as regards acts and habits, science and opinion can simultaneously remain about the same thing in the same mind.

Note: two genera of intellectual habits are found. Some are certain and evident; others are uncertain and non-evident. The former are the three enumerated by Aristotle (6. *Eth.* c. III*): *understanding, wisdom, and science. The latter are divided into those concerned with the false — such as error and ignorance — and those to which it is not incompatible to have the false or the true beneath them — such as opinion, suspicion, and doubt. Opinion taken generally is described as a determined assent to one part with fear of the opposite part — and can be divided into immediate and mediate. The reason for this is that just as among necessary things some are immediate and others mediate — about which there are distinct habits — so among opinables and contingents there are some immediate and others mediate, as the Doctor (in prol. q. V laterali, and 3. d. XXIV ad finem) and John of Mairs (1. Post. q. ultima) observe. Of the former there is immediate opinion; of the latter mediate opinion. Immediate opinion is defined by Aristotle (1. Post. T. XLIV)* as the assent of an immediate and non-necessary proposition — or: a certain assent of a thing that is probably known from its terms, with fear of the opposite part — as "a mother loves her child," which is commonly received by all as true, placed in the column of contingents. Mediate opinion is a certain assent given to something probable through a dialectical middle term — as "a man, because he is joyful, will do you a pleasing thing." Whether fear belongs to the essence of opinion is disputed by some Scotists — notably Tartaretus and John of Mairs (*præcit.*) — who affirm that fear, not actual but aptitudinal and radical, enters the essence of opinion, against Mair and Basle (*ubi sup.*) who absolutely deny that fear belongs to the essence and quiddity of opinion. The foundation of the affirmative side is that fear is placed in the definition of opinion, and also that through it opinion is distinguished from science — since opinion is of contingents which can be otherwise, while science is of necessities which cannot be otherwise. For necessary things are certain and infallible, while contingent things are uncertain and fallible. Hence Aristotle (1. Post. T. XVI*)* subjoins that what we know must be immutable, while what we opine can be otherwise. Doubt, moreover, is the hesitation of the intellect adhering to neither of the two opposed parts. Suspicion is that by which the intellect probably conjectures that this or that will or will not happen.*

The assertion is: science and opinion about the same object cannot simultaneously be in the same intellect. So Scotus (3. cit. §. *Ad I principale M.*). First proof: from Aristotle, who in the cited passage expressly defends the assertion set forth, adducing the differences that exist between science and opinion — which are faithfully and elegantly adduced and expounded by Zabarella and other interpreters of his. Second: diverse habits and acts cannot be about the same formal object, because — as I have repeatedly stated — habits and acts receive their denomination and specification from their proximate and formal objects. But the object of science is universal, necessary, immutable, and infallible; while the object of opinion is singular, contingent, mutable, and fallible — as Zabarella (*ubi supra*) notes from Aristotle. Therefore opinion and science cannot simultaneously be about the same object.

One may say: the simultaneity of the aforesaid habits and acts about the same object is possible through diverse media — one topical and another analytical. But besides the fact that this was already attacked concerning faith and science in the preceding article — which applies equally to what is commonly asserted about science and opinion — I argue specifically with Aristotle (*cit.*): it is incompatible for the same object to be capable of being otherwise and simultaneously incapable of being otherwise. But the object of opinion can be otherwise — because it is contingent; while the object of science cannot be otherwise — because it is necessary. Therefore, whether through the same or through a diverse medium, one and the same object is not simultaneously scientific and opinative.

Third: it cannot be that the same object is simultaneously estimated by the same intellect as certain and uncertain, as necessary and contingent — because two contradictory judgments simultaneously about the same thing in the same intellect would be admitted. But the assent of science is a judgment about a conclusion by which the object is judged certain and incapable of being otherwise; while the assent of opinion is a judgment about the same conclusion by which the object is judged uncertain and capable of being otherwise. If someone thinks differently about an opinable object, that comes from temerity and presumptuousness of spirit, as Tartaretus (*cit.*) notes — or from stubbornness and ignorance, as Aristotle (*7. Eth. cap. III**)* observes.

One may say: the intellect can deliver both judgments through distinct media, by reason of which there is no implication of contradiction. Against this: the intellect cannot judge a thing otherwise than it is from the side of reality — otherwise it would err and its judgment would be false. But the predicate of a scientific conclusion is necessarily conjoined with its subject. Therefore the intellect cannot judge that the same predicate is not necessarily conjoined with the subject of the same conclusion, lest it break into a contradictory judgment — and so the diversity of media does not remove the incompatibility just assigned. I add: the intellect is convinced by scientific truth and not convinced by apparent and probable truth, which is obtained through a topical medium. But it is incompatible for the same intellect to be convinced and not convinced with respect to the same object. Therefore, etc.

Fourth: the same thing cannot be simultaneously evident and non-evident — as I showed in the preceding article. But through science the object is evident; through opinion the object is non-evident — as is clear from its definition given in the note. Therefore science and opinion about the same thing in the same intellect cannot simultaneously be.

One may say: the argument concludes about the act of science and the act of opinion — not about the habit of one and the act of the other, or about the habit of both. Against this: acts and habits are concerned with the same object and are had through the same medium. For a habit is a readiness for producing acts

about the object with which it is concerned — through the same medium — as is clear from what was said in (*l. I**, 3. q. de qualitate)*. Therefore habits among themselves have exactly the same incompatibility as acts have with each other. But acts of science and opinion cannot simultaneously be about the same thing, as the arguments just given prove. Therefore also the habits of both do not simultaneously cohere in the same intellect about the same object. Moreover, the scientific medium removes the opinative medium: but with the object removed, the habit cannot persist. He who elicits a scientific act, therefore, cannot simultaneously retain the habit of opinion about the same thing. The major is known from what was said: for the object of opinion is uncertain and fallible — because contingent; while the object of science is certain and infallible — because necessary. Certitude and infallibility, moreover, expel uncertainty and fallibility — since they are mutually opposed. The minor is shown: habits and potencies do not seem to depend less on the object than on the subject, since they necessarily depend on both. Finally: the intellect through science is confirmed and stabilized in the object, while through opinion it is weakened and vacillates about the object. Therefore they cannot simultaneously coexist.

Some authors — at the Coimbrans (*1. Post. c. XXVI**, art.* III*, q.* II*), followed by two of our younger authors (*q. II*, disp.* XXIV*)* and Poncius (*disp. XXII**, concl.* VI*)* — argue that by divine power science and opinion can simultaneously remain in the same intellect. But this is not possible in the common opinion, nor is it to be tolerated in the Scotist school. For what is incompatible can be effected by no power — not even divine absolute power — as all scholastics hold by common consent. But the Scotists said so far have asserted that science and opinion cannot simultaneously persist because of the incompatibility they mutually exhibit — especially according to Scotus, who in (*loco cit. §. contra hat ante B., and ibid. sub G., and in Report. eadem dist. tertii*) openly teaches that science and opinion have incompatibility with respect to simultaneously inhering in the same intellect about the same object; and what is incompatible cannot be brought about even by supernatural power. Then, these two undivided Scotists at the end of the cited question approve the position of Tartaretus — whom a little before they attacked. Again, in (*q. II eiusdem disp.*) they accept the general description of opinion, which includes fear — which they seem afterward to disavow. Moreover, opinion is distinguished from science through uncertainty, which includes uncertainty and evidence. If, therefore, uncertainty and fear are placed in the definition of opinion, they are always connected together — and accordingly cannot be separated and segregated from each other. Furthermore: just as certitude and evidentiality are of the essence of science, and hesitation about both parts is of the essence of doubt, so fear is of the intrinsic nature of opinion. But a probable assent belongs to faith, doubt, suspicion, and opinion — therefore, to distinguish opinion from those, it must be asserted that fear enters the essence of opinion. And accordingly such an assent — as it abstracts from fear — is not opinion, just as animal as it abstracts from rational is not rational.

Moreover, given their position, all the contradictions and absurdities that we adduced above from Aristotle, Scotus, and others follow. Nor does it help them to say that opinion formally opposes science by reason of actual fear, because actual fear is not of the essence of opinion nor its passion — just as actual risibility is not the passion of man but is per accidens that man actually laughs. Moreover, the species of one genus are not opposed with respect to their actual being but with respect to their intrinsic and essential differences — as is clear from man and brute. Therefore science and opinion — which are placed under the same genus of quality — are said most principally to be incompatible in the same subject and about the same object not according to their actual certitude and fear, but according to their essential and quidditative being — as what I adduced above plainly demonstrates.

First objection: the same thing can be proved through a dialectical medium — which generates opinion — and demonstrated through an analytical medium — which produces science. Therefore it is not incompatible for science and opinion about the same object to be simultaneously had in the same intellect through diverse media. The antecedent is shown: about man an opinion can be acquired through a topical medium — namely "joyful" — and science through a demonstrative medium — namely "risible." First confirmation: one who has habitual science can not use it in act — for it is free to a man to exercise or not exercise the habits with which he is adorned. Therefore, while he is not actually thinking about the scientific conclusion, he can assent to the same conclusion through a topical medium — and thus he will simultaneously have science and opinion. Second confirmation: if the aforesaid assertion were true, no probable arguments should be provided before or after demonstrative ones — since they would do us no good; and yet that Aristotle and other philosophers not rarely adduce them, their writings plainly testify.

I distinguish the antecedent: simultaneously — I deny; successively — I concede. For it is impossible that the same thing is simultaneously known as evident and non-evident, certain and not certain, necessary and not necessary. To the first confirmation: Scotus (2. d. XLII*, qu.* IV*, D.)* responds that the two media are simultaneously incompatible in causing assent — and if one causes it, the other will cause nothing, being impeded by the stronger. For if the analytical medium is present, which is stronger and more efficacious, the dialectical medium will cause no assent, impeded by it. Why authorities and topical arguments are employed was said in the response to the second objection of the preceding article. To the second confirmation: a response and satisfaction were given there.

Second objection: one and the same potency inclines toward opposed acts — as the intellect toward assent and dissent, and the will toward willing and not-willing. Therefore it also inclines toward opposed and diverse habits, such as science and opinion. The consequence holds: because habits are generated in a

potency from repeated acts. Therefore just as a potency can elicit and receive diverse and opposed acts, so also habits.

I distinguish the antecedent: simultaneously and about the same object — I deny; successively and about a diverse object — I concede. I add that perhaps this does not hold in the will, as will be clear shortly. One may press: a man of loose morals, or one caught in some form of intemperance, if he repents of his corrupt life and produces an act of continence opposed to the habit of lust — which he still retains, for a habit is not suddenly destroyed by a single opposed act — will simultaneously have the habit and an act simultaneously opposed to that habit. And therefore opposed habits and acts can simultaneously exist about the same object in the same subject. This objection — touched upon by the Doctor (*3. d. XXXIII**, quæst. unic. sub B.)* — is accepted by Poncius (*disp. XXII**, concl.* VII*)* and made much of by him (*ibid.*), not noticing that it is evidently against Scotus — both there and in (*6. Met. quæst. I**, not far from the beginning)*. The parity can be denied from the same Doctor in that place — especially in I — since science and opinion are intellectual habits, while temperance and intemperance are moral habits. The intellect, namely, is necessitated and convinced by a necessary and evident object; whereas the will, which is rational appetite, is by its nature indifferent, and according to its inclination can desire this or that and desist from it — even though one who has a habit is more inclined toward the object of that habit than toward its opposite, whose habit he lacks.

Third objection: contrary qualities in remitted degrees can be compatible in the same subject — as is clear with lukewarm water, in which heat and cold are simultaneously received in remitted degrees. Therefore even more so can science and opinion coexist — since they do not have as great a mutual incompatibility as those qualities have.

The parity is to be denied: because contrary qualities are not caused by the object — about which Scotus is correct — whereas science and opinion are. Therefore they cannot simultaneously be about the same thing.

Natural Philosophy, or Physics

*of Fr. Bonaventure Colombo of Nice, Minor Conventual,
Professor of Sacred Theology. According to the Mind of the
Subtle Doctor.*

Preface

Having set forth what pertains to the method of knowing, or to a thorough acquaintance with Dialectic, we now follow the order of doctrine and, with God as our guide, take up Physics. For, as the Philosopher testifies (*2. Met. T. 15.*), it is absurd to seek science and the method of knowing simultaneously. It is certainly fitting and profitable, once the method of knowing has been obtained, to pursue and acquire science, or Physics. And so, having passed through the arid and sandy fields and the thorny plains of Dialectic, we enter the fruitful, flowery, and pleasant storehouses of natural philosophy, which we shall attain with greater ease of understanding, shall find no small delight, and shall make our way toward those things that are above nature — as Augustine forewarns (*1. de ordine cap. 11. Et 1. Retract. cap. 6.*).

The treatment of Physics, moreover, is extensive. For it encompasses the natural body, concerning which and its properties taken universally the discussion proceeds in the eight books on physical hearing; the celestial and elemental body, treated in the four books on the heavens and the world; the generable and corruptible body, treated in the two books on generation and corruption; the imperfectly mixed body, treated in the four books of the Meteorologica; the perfectly mixed body, treated in the book on metals and stones; the animated body, treated in the book on the soul, on the generation of animals, and in those works called the Parva Naturalia. Following the order we have proposed, taking our beginning from the work on physical hearing, we shall establish eight books. The first, On the Preambles to Physics. The second, On the Principles of the Natural Body. The third, On Nature and Art. The fourth, On Causes. The fifth, On Quantity. The sixth, On Place. The seventh, On Time. And the eighth, On Motion.

Book I. On the Prolegomena to Physics.

Relying on the order already set out and prefixed by us, we bring forward and discuss the preliminary questions in the present book, as we do in our Logic and other works, with as much diligence as we can. For once the origin, name, utility, excellence, and nature and object of Physics have been understood, we shall arrive at knowledge of all the rest more easily and exactly.

Question I. On the Discovery and Utility of Physics.

Article I. Who is the Discoverer of Physics?

The origins, names, and classes of philosophers, their sects, successors, and leaders, their customs, their modes of philosophizing, and the times in which they flourished — all these are recounted abundantly and eloquently from Laërtius and Augustine by Vives in his commentary on Augustine's *City of God*, book VIII, and by Fonseca likewise in his preface to the *Metaphysics* (*Viues in comm. 8. Ciuit. eiusdem August. Conimbr. in proæm. Dia. & Fonf. pariter in proæm. Met. 3.*). Concerning the name of philosophy, its acceptation, and its division, I treated briefly in the *Logic* (*Log. lib. 1. quest. 2. art. 10.*), and more copiously Augustine in the place now mentioned. And concerning the discovery of the arts and sciences I touched on certain matters there (*quast. 1. art. 4.*). The discipline which we now intend to examine is called philosophy in the absolute sense, and commonly natural philosophy, as its very name indicates. For Physics, which is also called physiology, is the same as discourse or science about nature. For what the Greeks call φύσις, the Latins call *natura*. This discipline, indeed, contemplates the natural body, its principles, causes, and properties, as will be clearly established throughout its entire course.

Nor should it pass without remark that the ancient philosophers before Socrates devoted all their effort to the knowledge of natural things, as Laërtius testifies concerning Plato (*Laër. in Plat.*). The pursuit of philosophy once moved in the province of Physics alone; Socrates came along and added Ethics, and Plato added Dialectic — as Augustine writes (*August. vbi supra cap. 3.*) and Vives in the same place. And certainly, since natural and material things are known by us before supernatural and spiritual ones, and since they are more accessible to our senses — which are the first guides of our knowledge — in keeping with that scholastic dictum often repeated, drawn from the book *On Sense and the Sensible* (*lib. de sensu, & sensato cap. 1.*): "Nothing is in the intellect that was not first in the sense" — therefore the first philosophers rightly philosophized first about these things, so that, having come to know them, they might afterward be able to arrive at knowledge of spiritual and heavenly minds and of the supreme God, as though by certain steps. This is noted by Augustine (*Aug. 6. Musica, & 8. Ciuitat. propè finem cap. 3. Et 1. Retract. cap. 11.*), from whom the Doctor does not depart (*1. distinctione 17. quest. 1. 4.*).

Assertion: the primary discoverer of Physics is God; its secondary author is held to be Thales of Miletus. The first part is derived from Scotus (*libro de primo rerum omnium principio*) and other places where he teaches that God is the primary origin and source of all sciences. It is proved in roughly the same manner as it was proved in the passage just cited that Logic flowed from God as from its first source. For there is one Teacher of ours, God (*Matt. 23.*), who teaches man knowledge (*Psal. 92.*). Indeed, "we are not sufficient to think anything of ourselves as from ourselves, but our sufficiency is from God" (*2. Corinth. 3.*).

"What do you have that you did not receive? And if you received it, why do you boast as if you had not received it?" (*1. Corinth. 4.*).

This is confirmed from the historical record. For it is held as certain among all Latin authors that they learned the liberal arts and philosophy from the Greeks, as is evident from Cicero (*Tullio 1. off.*); and that the Greeks received them from the Egyptians is attested by Jerome in his epitome to Paulinus and by Laërtius (*Hieronym. in Epitome ad Paulinum, & Laër. lib. 7.*); for among the Greeks, Plato came to Egypt for the sake of learning, as Augustine affirms (*Aug. 8. Civitatis 3.*). Then that the Egyptians and Chaldaeans were instructed by the Hebrews, specifically by Abraham and Moses, is narrated by Josephus (*Iosephus 1. contra Apionem*), Eusebius (*Eusebius 10. de præparatione Euang.*), and Berosus (*Berosius 3. Hist.*). Furthermore, that the Hebrews received Physics and other learning from the children of the first parents, and these from Adam, and Adam himself from God, is written with one pen by the annalists of the world. Moreover (*Gen. 2.*), Adam assigned names to things, "and whatever Adam called a living creature, that was its name." This he could not have done without knowledge of those same natural things, which undoubtedly pertains to Physics. And he who brought the animals to Adam himself so that he might give names to them plainly bestowed on Adam a knowledge and science of them as well, without which he could not have called them by their proper names.

The second part is handed down by the Doctor (*Doct. in comm. 1. Met.*) and proved by the testimony of the Philosopher just cited (*cap. 3.*), who makes Thales of Miletus, one of the Seven Sages of Greece who lived in the time of the prophets Ezekiel and Daniel, the discoverer of Physics. The same is written by Augustine (*Aug. 8. Civitatis 2.*), Vives in the same place, and other later chroniclers. Again, that Pythagoras greatly enriched Physics, and that Aristotle reduced it to a better form, is the common view among philosophers. Moreover, what Themistius left in writing should not be passed over. Although Thales and other discoverers of the sciences are celebrated by all, it is not to be thought that they were the first authors of those sciences; rather, after the Thessalian flood which under Deucalion almost destroyed all of Greece, those men of keener intellect, taught by the Egyptians, restored those sciences.

Physics was, moreover, discovered through the direct act of the intellect, as is clear from Aristotle (*1. Met. cap. 2.*). For wonder — from which the Stagirite says philosophy drew its origin — is a direct act of the intellect. Furthermore, Physics speculates about sensible things, which, since they are directly attained by our senses, it evidently follows that Physics was acquired through the direct act of the intellect.

Article II. Whether Physics Is Useful.

That every science is a good is subscribed to with common pen by Aristotle (*1. de anima 1.*) and his commentators. For since every human being by nature desires

knowledge (*1. Met. 1.*), and natural appetite tends toward the good, it plainly follows that knowledge is to be numbered among goods. Since the good is divided into the useful, the delightful, and the honorable (*1. Eth. 8.*), science appears to share in this threefold good, as the Philosopher clearly expounds in the cited passage from the *De anima*. Indeed, science obtains the honorable good, inasmuch as the intellect rightly desires it and the will fittingly covets it. It enjoys the delightful good, in whose existence and presence our intellect takes great delight. It also enjoys the useful good, since it is ordered toward speculation, if it is speculative, or toward action, if it is practical. For the utility of science is not to be measured by monetary gain, but by the eminence, dignity, and perfection of the knowledge of things, by which our mind is adorned, illuminated, and perfected, so that it may afterward be raised to know objects that are more excellent and more worthy. Hence Saint Augustine writes (*1. de doctrina Christiana*): "Making our way toward blessedness by means of those things which we are to use, we are aided and in some sense supported, so that we may arrive at those things that make us blessed, and abide in them."

Assertion: Physics is beneficial to the other sciences. This is indicated by Aristotle (*1. animæ T. 1.*), Scotus, and the followers of both (*ibidem*), who affirm that the science of the soul — which is the principal part of Physics — belongs to the genus of the honorable sciences (*T. 2.*), and that it contributes to all truth, and most of all to natural science. If a species is beneficial to certain things, there is no doubt that its genus is equally beneficial to the same. Therefore, what has been made by God is plainly useful, in keeping with that common dictum (*1. Cæli T. 32.*): "God and nature do nothing in vain." That Physics has proceeded from God was demonstrated in the preceding article. Again, through knowledge of natural things our intellect is perfected and prepared, especially for receiving the knowledge of other things. Hence Augustine (*1. Trin. 1.*) writes: "Sacred Scripture uses words and bodily things so that, step by step, our intellect may ascend to divine and sublime realities." The Parisian masters add (*Parisienses ful. 1. primi Phys.*): its utility consists in having perfect knowledge of natural things, which is the ultimate disposition of man toward happiness and eternal life.

Furthermore, its utility and benefit can be urged by induction, running through the individual sciences. First of all, it helps Dialectic, which treats of second intentions, which are founded upon first intentions. Now it is well established that many first intentions pertain to Physics. Moreover, reflexive and comparative knowledge presupposes direct knowledge: the former pertains to Logic, the latter to Physics. Again, our knowledge takes its beginning from sensible things, which are the subject of Physics' consideration, and it is recorded (*1. Met. 1.*) that experience of individual material things begets science in us. And so, since all the intentions of Logic rest upon these first things which belong to Physics, it is clear that the latter is beneficial to the former. Furthermore, it contributes to the mathematical disciplines, inasmuch as these meditate on quantity — immense matter and its properties and accidents —

while those contemplate quantity separated from matter. This can be brought to bear on individual cases: in Astrology, since Physiology disputes about the heavens and the world, their properties and accidents; in Music, because it surveys sound, voice, and its instruments; in Geometry and Arithmetic, since the one investigates continuous and the other discrete quantity. It also serves Medicine, since it inquires into the natures and powers of herbs, plants, animals, the human body, and other things that assist it. This is not obscurely indicated by the philosophical maxim introduced and explained by me (*lib. 5. Log. quæst. 4. art. 7.*): "Where Physics ends, Medicine begins." It is equally an aid to Ethics, since it considers the natural and free powers, their acts and habits. Nor does it harm Metaphysics, since through the motion of the heavens we arrive at the existence of the Angels who move them and of God, the first mover. And it is not useless to Theology. For as Augustine pursues at length (*D. Aug. 8. Ciuit. 6.*): "From movable things to one immovable, from mutable things to the immutable God, from corporeal things to the supreme incorporeal, and from visible creatures to the invisible Creator, we arrive at knowledge." As the Apostle writes (*Rom. 1.*): "The invisible things of God, through those things that have been made, are clearly seen and understood — his eternal power and divinity." I add that many physical matters occur in sacred Scripture which cannot be grasped without knowledge of this science, just as concerning the arts, and specifically concerning Dialectic, Augustine aptly teaches that they are of great value for penetrating and resolving what is in the sacred text (*August. 2. de doctrina Christiana cap. 31.*). Hence, recognizing and appreciating its utility, Thales of Miletus and others of that class endured many labors and sweats in devotion to its study, as Vorrilong lucidly shows (*Vorrilong. in Prol. primi sentent.*).

As for the delight and pleasure it affords a person, Cicero (*Cic. 2. Acad. quæstionum*) and Aristotle (*Aristot. 10. Eth. 1. & indè*) commit to writing in their characteristic eloquence what was certainly experienced by those who, out of love and admiration for it, said farewell to the enticements of the world and the pleasures of the age — a long catalogue of whom is woven by Vorrilong in the place cited above. For it is a speculative science to be sought for its own sake, on whose pleasant and sweet nourishment our soul feeds, is nourished, and grows in the present, so that in the future it may be nourished on another invisible food and enjoy the blessed life — as Augustine (*August. 1. de dotr. Christ. cap. 1.*) and Hugh of Saint Victor (*Hugone vict. libro primo de Arca Noë*) intimate.

One objects, first, that Saint Paul, cited by Augustine (*Aug. 8. Cinit. cap. 9.*), warns and deters us from the study of philosophy (*Coloff. 2.*) with these words: "Lest anyone deceive you through philosophy and vain deceit." Added to this are Tertullian (*Tertul. contrà Hermog.*): "Philosophers are the patriarchs of heretics"; Gregory Nazianzen (*Nazian. orat. de modestia seruanda*): "Like the plagues of Egypt, philosophers have crept destructively into the Church"; Jerome (*Hieron. in Epist. ad Iulia.*): "The philosopher is the plaything of glory and the cheap slave of popular applause"; and Hugh of Saint Victor, addressing his soul: "The image

deceives you, O my soul. For these are not wisdom but human madness — those studies in which the imprudent and the foolish, with labor as useless as it is stubborn, inquire into the natures of things, while they remain ignorant of their Author and of the Artificer of all natures." From these and similar testimonies of the saints it is concluded that natural philosophy, and any other philosophy, is not profitable but harmful to the Christian commonwealth.

I respond: the passage from Paul cited carries its own solution. For there it is written, "through vain deceit" — that is, through sophistic deceit, which is rejected (*Ecclesiastici* 37.): "Whoever speaks sophisticatedly is hateful." Then it is added: "according to the tradition of men, according to the elements of the world, and not according to Christ." Therefore, philosophy that is not from God, that does not accord with Christ, but has been craftily introduced by a deceiving man using it to bring in errors — that philosophy is certainly to be rejected as evil and harmful. Hence Augustine writes (*August. 3. conf. 4.*): "There are those who seduce through philosophy, coloring and painting over their errors with a great, appealing, and honorable name." Against such persons the warning of Paul and of the others whose words I cited above is effective. All the more so from the same Augustine (*August. 1. de ordine cap. 11.*): "Sacred Scripture commands us not to shun and mock philosophers absolutely, but philosophers of this world." Finally, that Moses was instructed in all the wisdom of the Egyptians, from which Physics is not excluded, is related by Augustine himself (*Aug. 2. Doct. Christ. cap. 40.*).

One objects, second, that magic is a part of Physics, inasmuch as it regards the mutual sympathies, the hidden powers of things, the intimate and concealed natural causes which, when combined and linked together, produce marvelous effects by which people are led into wonder and stupor — as is apparent from Alexander of Hales (*Alenf. 3 part. quest. 16. num. 3.*) and Saint Bonaventure (*S. Bon. 2. distinct. 9. quæst. 3.*). But this is condemned as nefarious and harmful to mankind by civil law, as is clear (*Cod. de malef. leg. Nemo, leg. culpa*), and by canon law (*quæst. 6.*). Therefore Physics is not beneficial to man but harmful. I grant the major and to the minor I say: what is reprobated is malefic magic, which is mixed up with sorceries, witchcraft, and dealings with demons, as may be seen in Augustine (*Aug. 10. Ciuit. cap. 9. & 10.*), Alexander of Hales, and a great many others — not natural magic, which teaches how to apply active forces to passive ones, from whose application and approximation admirable effects are produced without any intervention or patronage of the evil spirit, as will be made clear in the book on nature and art. The use of this natural magic, however, is prohibited by the Catholic Church, as is read in a certain Bull of Sixtus V, on account of the great danger that men incur in learning, practicing, and professing it: "For he who loves danger shall perish in it" (*Ecclef. 3.*). For it is to be feared that, in those things which are difficult to grasp and to perform, a person affected with the desire of knowing and doing, and led astray, may become entangled with a demon who teaches and fulfills magical arts.

One objects, third, that Physics draws one away from civil affairs, human society, the study of sacred Scripture, and other things that greatly contribute to the common good. For he who is devoted to Physics is wholly absorbed in probing its object and properties; therefore Physics does not benefit man but harms him. Add that all heresies have flowed from philosophers, as Jerome (*Hierony. l. contra Pelag.*) and Tertullian just cited attest.

I respond: in every well-ordered and well-constituted commonwealth, some apply themselves to civic affairs, others to divine, some to practical, and others to speculative matters, and all their studies and labors redound to the common utility, as the Apostle intimates (*1. Cor. 12. Et Eph. 4.*) and as is found (*Luc. 10.*) in the names of Martha and Mary Magdalene, by whom the active and contemplative life are signified, as the sacred interpreters note there. To the other objection that is appended, I say that it is not philosophers absolutely but those who philosophize badly who are to be reproved and condemned, as I was saying in response to the first objection. And so Physics in itself is good, even though the wicked make bad use of it. Sacred Scripture too, being from God, is most excellent, even though heretics draw false and erroneous propositions from it, as Augustine declares (*August. l. de vera Religione cap. 20. 1. contra Cresconium cap. 23.*): "There are many things which, though good and instituted for some useful end, are not useful to all who have them, but only to those who use them well. For the same light bathes both healthy eyes and diseased ones — to the latter it is torment, to the former an aid. The same food nourishes some bodies and harms others. The same medicine cures some and weakens others. The same weapons protect some and impede others. The same garment covers some and entangles others. So too Baptism avails some unto the kingdom, others unto judgment."

Article III. What Rank Physics Claims Among the Other Sciences.

Many and diverse views of the philosophers are related, particularly among the recent ones — Toledo (*Tol. in prol. Phys. c. 3.*) and the Coimbrans (*Conimb. ibid. quest. 5. art. 1.*) — concerning the order and place that the parts of philosophy occupy among themselves, which I touched on (*l. 1. Log. q. 1. art. 6.*) and there briefly tasted and explained the twofold order of nature and of doctrine. I note here, however, that the order of doctrine has been introduced by human beings, whereas the order of nature was not instituted but rather discovered by them — as Augustine testifies (*Aug. 2. Doct. Christ. c. 32.*): "Just as one who narrates the order of times does not compose that order himself, and one who shows the sites of places or the natures of animals, serpents, or plants does not display things instituted by men, and one who demonstrates the stars and their motions does not demonstrate a thing instituted by himself or by any man." Thus, since the sciences preserve the same order of nature as their objects enjoy, such an order of nature must be established among them as exists among those same objects. Wherefore Metaphysics is first in the order of nature, for its object,

which is being, is first. After Metaphysics comes Physics, which meditates on corporeal substance; then Ethics follows, which, since it instructs the morals of human beings, must come after consideration of human nature, its faculties, and its physical acts — which pertain to Physics — to a discourse on their morality, or goodness and evil, about which Ethics discourses. After this comes Mathematics, which surveys quantity, which is preceded by substance (*7. Met. 1.*). Dialectic holds the last place in the order of nature, for it arose from those preceding disciplines (*vbi supra art. 5.*). To this, however, the order of doctrine seems to be opposed. For those things which are prior in the order of nature are said to be posterior in the sequence of doctrine. Hence in our time, by the common assent of philosophers, the order of doctrine in the schools is: first Logic is taught, then Mathematics, afterward Physics, then Ethics, and lastly Metaphysics.

Assertion I: Mathematics in the order of doctrine is to be placed before Physics. This is intimated by the Doctor, who (*3. d. 34. D.*), enumerating the three aforementioned speculative sciences, takes his beginning from Mathematics; and (*6. Met. 9. 1.*), in drawing out the sufficiency of the said sciences from the threefold theoretical object, addresses the object of Mathematics before that of Physics. Orbellis adds (*Orbel. in proæm.*), in the consideration of Mathematics, declaring that he follows Scotus in all things, and openly teaches that Mathematics precedes Physics. The same is the view of Augustine (*Aug. 2. de ordine 15. Et indè*), Plato (*Plato. 7. de Rep.*), and many others. This is proved first from Aristotle (*1. ex Arist. 6. Eth. c. 8.*), who affirms that boys can be mathematicians but not yet wise in the manner of philosophers or physicists. The reason is that Physics requires long experience of things, which is not necessary for grasping Mathematics. Second, Mathematics treats of more evident and better-known things; hence its demonstrations are said to share in greater evidence than those of Physics (*2. Met. 16. & 8. Top. 2.*), as I proved (*1. 1. de anima q. 2. art. 2.*). For Physics deals with things intimate and hidden in nature. Again, accidents are better known than substance. For, as is read (*1. animæ, Top. 31.*), "accidents contribute greatly to the knowledge of substance." Since, therefore, Mathematics concerns itself with quantity, which is an accident, and Physics with the natural body, which is a substance, it is clear that Mathematics must be learned before Physics.

Physics ought to be taught before Ethics. This is drawn out and gathered from the Doctor (*Quol. 5. art. 1. Et Gadio ibid. fol. 183. colum. 4.*), who, treating of the goodness of a natural and a moral act, explain the natural first and the moral afterward, and from the description of the former they draw the description of the latter — and rightly so, since the moral derives its origin from the natural, just as Medicine derives from Physics. Therefore, just as Physics is taught before Medicine, so too in the order of doctrine Physics is to be preferred to Ethics. Augustine adds (*Aug. 8. Cinit.*), who at (*c. 4.*), adducing the tripartite division of philosophy into rational, natural, and moral, treats first of Physics (*6. eiusdem lib.*)

and then of Ethics (*cap. 8. 10.*). Furthermore, the ancient philosophers devoted themselves first to physical and then to moral matters, as is evident concerning Socrates from the Doctor cited (*cap. 3.*), who, having left physical matters, devoted himself entirely to moral ones — an order and custom retained by Aristotle, as is clear from the arrangement of his books. Hence (*1. Eth. 3.*) he writes that a young person is not suited to be a hearer of moral philosophy. And in Augustine (*Aug. 4. Conf. 12.*), a certain bishop wisely declined to engage with Augustine himself (though his mother urged it strongly) and to discourse on his conversion, because the said Augustine was then still a young man, overly ardent, unteachable, and puffed up with the novelty of the Manichean heresy. For the correcting and ordering of morals, a firm judgment about matters of action, experience and prudence, a calm and peaceful mind — such as an adolescent does not possess — and many other circumstances are required, which Scotus enumerates and explains (*Scot præcit.*) and touches on (*q. 4. prol. antè DD.*). Moreover, the intellect is first illuminated by the light of knowledge of things before the will is set aflame by the flame of love and desire for those things. Hence the common saying: "the will does not tend toward the unknown." And of Saint Bonaventure it is written in his life that he ruminated with feeling on every truth that he grasped with his intellect. Furthermore, Philosophy is called by the philosophers the medicine of the body, because it was invented to cure the disease of the body, which is ignorance of natural things. Ethics, however, is called the medicine of the soul, since it was discovered to heal the sickness of the soul, which is moral wickedness. But since the body is known before the soul — for spirit, being further from the senses, is more remote — therefore Ethics is posterior in the order of doctrine to natural science.

Assertion III: Metaphysics is to be learned last. So Scotus (*Scotus 1. d. 3. quest. 2. §. Loquendo.*), and Avicenna after him (*Sub. M. post Auic. 1. Metaphysica, cap. 3.*). This is proved first: our knowledge is raised from the lowest to the highest, from small things to great, from the lowest to the supreme, from the corporeal to the incorporeal, and from natural to supernatural — as Augustine philosophizes well (*Aug. 8. Cinit. 6. Et 1. Retract. 3. Et 7. conf. 17. Et 6. de vera Religione 29.*). But Metaphysics treats of the sublime, the great, the supreme, the incorporeal, and the transnaturals — as its very name indicates. For, going by the force of the name, it is the same as what is transnatural (*Arist. 1. Met. 2.*). Therefore, in the order of doctrine, Metaphysics is to be placed after the other disciplines. Second: those things which are most remote from the senses, most abstract, and most universal are the most difficult to know and are known by us last. But Metaphysics concerns itself with those things which are most distant from sense, and which are transcendent and most universal (*Philos. vbi supra*). Furthermore, what is first in the order of distinct cognition is last in the order of confused cognition, as will clearly appear in the next question. But Metaphysics is first in the series of distinct cognition — for it is first philosophy, the supreme and universal science that confirms and fortifies the principles of all the sciences

discovered by natural light, as the Philosopher and all the others confess with common voice. Therefore, in the order of doctrine, Metaphysics holds the last place among the disciplines.

Against Assertion I, it is objected from the part of Tataret (*Tatar 1. Phyf. quest. 1. scibili 2.*) and the Parisians (*Parisiensium ibid. q. 2. conc. 2.*): from one extreme to the other there is no passage except through the middle (*Scot. in Report. 2. d. 1. q. 7. post Aug. 1. Musica, c. 12.*). This can be illustrated from continuous motion, from whose starting term there is no passing to its end term except through the intervening middle; and from the foundations of a house, to the roof of which one does not ascend except by traversing its intermediate parts. But between Physics and Metaphysics, Mathematics acts as the middle: for Physics abstracts neither really nor rationally from matter, while Metaphysics abstracts really and rationally from matter. Therefore Physics is to be taught before Mathematics. It is confirmed: the starting point should be from easier and better-known things (*5. Met. cit. à Parisienf. vbi supra*). But what Physics treats of is easier to know, because closer to the senses. Therefore one should begin from Physics rather than from Mathematics.

It can be responded, with the cited Scotus (*in fol. 1. §. Ad aliam probationem*): the major holds for a middle that is necessary for the attainment of one extreme, as the instances already given show — but not for a middle that is not necessary, as God acts through intermediate causes and yet can act without them. Or, if the major is granted, the minor is to be distinguished. Mathematics is the middle between Physics and Metaphysics in respect of abstraction — granted; in respect of attainment and the order of doctrine — denied. To the confirmation: I grant the major, I deny the minor. For Mathematics concerns more evident things and things easier to know, as was proved in Assertion I.

One objects, second, against Assertion II, from the part of Zeno, Diogenes, and other ancients: only those imbued with good morals are fitted for undertaking Physics. For a flood of vices impedes and constrains the mind from contemplating the truth of things. Therefore, as Plato in the *Phaedo* and Seneca warn, whoever is not free from the enticements of the world and the corruption of vices cannot, cannot philosophize. Therefore one must begin with Ethics and not with Physics. I respond: there is no doubt that it is greatly helpful to one who wishes to learn the precepts of philosophy to be separated from vices and estranged from corrupt habits. For, having cast aside the pleasures of the world and having restrained the passions of the soul, one contemplates truth more freely and conveniently — as I indicated from the example of Socrates and others (*art. 2.*) and as Augustine pursues elegantly (*Aug. 8. Cinit. 3.*). Nevertheless this is not necessary, since many who are entangled and ensnared in earthly desires excel in Physics and other sciences — among whom Augustine himself before his conversion is clearly numbered, as is evident from his *Retractations* and *Confessions*, especially (*l. 3. 6. 4. q. 1. 8. c. 7. 9.*). You will say (*Sap. 1.*): "Into a

malevolent soul wisdom shall not enter." Therefore a wicked person imbued with corrupt habits is not capable of moral philosophy, which may not inaptly be called wisdom. I say that this saying is to be taken of charity, or of the knowledge that is joined with grace and which is called sapid knowledge, as I observed (*1. f. Philosophia Moralis q. 3. art. 2. dub. 1.*) and indicated in the Logic (*1. s. quæst. 4. art. 1. in resp. 1. oppos.*). Nor is it necessary that the moral philosopher be filled with charity, as is clear from the pagan philosophers, who lacked grace and charity.

One objects, third, against Assertion III, from Bonetus (*Bonet. 1. Phys. cap. 1.*) and Mirandola (*Mirand. 3. de sing. cert. sect. 2.*): Metaphysics speculates on transcendentals and on predicates that are most universal, and on the highest and supreme causes of things, without which the objects of other sciences cannot be clearly and distinctly known — therefore, in the order of doctrine, Metaphysics is to be placed before the other sciences. I respond with the cited Scotus (*sub N.*): the argument concludes with regard to the order of nature and of distinct cognition, but not with regard to the order of doctrine and of confused cognition. Wherefore, Metaphysics is first in the former order and last in the latter order.

Article IV. On the Order of Dignity of Physics and the Other Sciences.

By the greater or lesser dignity and nobility of the sciences in the present article is understood that which pertains to them, both among the speculative sciences and among the practical ones; and it is inquired whether the speculative sciences surpass the practical in nobility, and which of these and those holds first place. Since the excellence and eminence of a science is derived from its object, that science is judged nobler which has a nobler object (*6. Metaphysica 2. 11. eiusdem operis, f 6. Et Scot. ibidem*). For a more accurate inquiry and easier understanding, it is necessary to know that the object of speculative science in general is the speculable, and that of practical science is the operable. The speculable object is set down as threefold, from what was said in the Logic (*Log. lib. 5. quest. 4. art. 6.*), which constitutes threefold speculative science. The first is being taken universally, under which are contained God and substances, which are considered by Metaphysics. The second is the natural corporeal substance, which Physics speculates. The third is quantified substance, which pertains to Mathematics. The operable, or practical, object is determined to be twofold, through which there is a twofold practical science: the active and the productive. The former pertains to the active science, which directs morals; the latter pertains to productive science, which occupies itself with external and manual works.

Assertion II: speculative science surpasses practical science in dignity. This is the position of Aristotle (*1. Metaphysica, cap. 2. Et 6. eiusdem operis, cap. 1. & 2.*) and Scotus (*ibidem & quest. 4. prol.*). It is proved first by the same authors: it is nobler

to be for oneself and for one's own sake than to be ordered toward another and to serve it, because the former designates a kind of independence and the latter a dependence on another — and it is simply nobler not to depend than to depend on another, as is clear from God, who is absolutely independent, and from the creature, which is dependent. But speculative science is for its own sake and is sought for itself, while practical science is for the sake of work and use. Therefore speculative science precedes practical in nobility. Second, speculative science was discovered to flee ignorance; practical science was discovered on account of the need for work and the necessity of carrying on life. Hence the Stagirite testifies in the place cited that men, stirred and provoked by wonder at effects and by ignorance of causes, were brought to philosophize; and that, once all necessities for sustaining life had been obtained, they applied themselves in leisure to acquiring speculative doctrines — particularly the mathematical ones, whose inventors were men of leisure, namely the Egyptian priests, as the same Aristotle relates in the same place. Third: the greater or lesser nobility of a science is derived from the greater or lesser excellence of its object (*initio huius articuli*). But the object of speculative science is worthier than the object of practical science — as can be brought to bear on any speculative or practical science, adduced and explained before this assertion. Furthermore, the end of practical science is the work, but the end of speculative science is truth, in the enjoyment of which Augustine confesses that blessedness is situated (*10. conf. cap. 13.*).

Assertion II: among the speculative sciences, Metaphysics is preeminent in dignity; then Physics follows; Mathematics comes after. Among the practical sciences, the active is more worthy than the productive. The assertion is fourfold. The first part is expressed by Aristotle (*1. Met. cap. 2.*), fortified there by the same and by Scotus in the same place and (*1. dist. 3. quest. 2. §. Loquendo sub N.*): that science is most noble which has the most noble object; but Metaphysics speculates on the most noble object — namely God and abstract substances (*Arist. ubi supra*). Therefore it is called divine, first science, first philosophy, the contemplator of first principles and causes, and wisdom — which to possess, and to possess most perfectly, belongs to God alone, as the same Aristotle adds in the cited passage. Second: it is better and nobler to command than to be subjected, to direct than to obey. Hence the same author in the passage noted says: "It is for the wise man not to receive instructions but to give them, and not for the wise man to follow the judgment of another but for the less wise to follow his judgment." But Metaphysics is the queen and mistress of the sciences, to whom the other sciences, as her handmaids, are obedient (*3. Met. cap. 2. T. 3.*). Then (*1. Post. cap. 8. T. 23.*), Metaphysics regards the common and first principles of the other sciences. For it considers the quiddities of all things in common and in the universal, as the Doctor writes, cited by Orbellis (*Orbel. 1. Met. cap. 4.*). Again, Metaphysics explains, confirms, and corroborates the principles of the other sciences, as after Avicenna the same Doctor asserts in the first cited passage.

Furthermore, Metaphysics is first in the order of nature and in the method of distinct cognition; therefore it rightly holds primacy among the sciences.

The second part is that of Aristotle and Scotus (6. *Met. in cap. 1. T. 3.*), who say that if there were no spiritual substance, natural philosophy would be found first among the sciences, just as Metaphysics now holds the citadel among all of them. This is proved first: substance is worthier than accident (7. *Met. T. 4.*), where the Doctor (*quest. 2.*) says; and among corporeal substances, the natural is nobler than the quantified, because the former is the principle of motion and rest, while the latter is set down as the principle of no action, since quantity does not belong to the genus of the active. Therefore, since Physics contemplates the natural body and Mathematics the quantified body, second place among the parts of philosophy is fittingly assigned to Physics. Second: Physics discourses about the animated body, as is clear from the book on the soul; Mathematics, however, about the body consisting in three dimensions, which is precisely devoid of soul. But whatever is living and animated is to be preferred to whatever is inanimate and not living, as Augustine teaches (*lib. de vera Relig. cap. 29.*) and the Doctor accepts (*Quol. 1.*). Therefore, after Metaphysics, Physics is more excellent — "whom Medicine, as a sister, does not forsake, sitting at her side."

The third part follows from what precedes, defended by Aristotle and Scotus in the same places. For since quantified substance is the object of Mathematics, as stated in the passage just recalled, it consequently holds the third seat of dignity among the speculative sciences, which is given to it in accordance with the third place that its object occupies among the speculables. Especially since no other real speculative science acquired by the powers of nature is found besides those three enumerated — and therefore that order of nobility already assigned is to be maintained. Since, however, Mathematics is primarily twofold — Arithmetic and Geometry — it can be doubted which of them is principal. To this difficulty Orbellis and the Coimbrans (*Orbel. citatus, & Conimbr. articulo quarto*) respond, affirming that Arithmetic is to be placed before Geometry in dignity — to which I willingly subscribe. For (1. *Met. cap. 2.*), that science is more certain and accurate which concerns simpler and more abstract things. But Arithmetic treats of unity, which is the principle of number, and which is prior to the point, which is the principle of the line — since the point adds position in the continuum over and above unity. Furthermore, Geometry derives its demonstrations from Arithmetic. For proportion in magnitudes is drawn from proportion in numbers. Hence Euclid rightly placed Arithmetic before Geometry. Close to Arithmetic stands Music, subalternated to it, which considers the number of sounds — and which Augustine treats piously and fruitfully in his six books. Geometry is closely followed by Perspectiva, subalternated to it, which regards the visual line, of which there is an extensive treatment in the Perspectiva of Alhazen, cited by the Doctor (2. *distinct. 13. quest. vn. §. Quantum D.*). Not far from these stands Astrology, which meditates on the

motions of the stars and uses mathematical principles to investigate their effects and natural properties. Hence it is judged by the aforesaid Orbellis to be midway between Physics and Mathematics.

Now, which of these excels in certainty and evidence as regards the knower is something that can be called into question. This may be resolved by saying that, as regards us, the mathematical sciences are more certain and evident, because mathematical things are more patent to us and require less experience than natural and divine things. Aristotle (*1. Eth. 3. Et 2. Met. 3.*), Scotus, and other philosophers in the same places support this view. But absolutely speaking, Metaphysics is more certain and evident. The reason is given by Aristotle (*1. Met. cap. 1.*): that science is most certain which occupies itself with the most universal things and constructs its demonstrations from the simplest principles — and it is clearly established that this is Metaphysics, which contemplates the transcendentals and divine things, which are most certain, most firm, and most evident by their own nature, even though they are attained but little by us, since our intellect stands in relation to them as the eye of the owl to the light of the sun (*2. Met. 1.*). This doctrine Scotus teaches perspicuously (*1. d. 3. quest. 2. §. Nunc f. De ordine perfectionis*): I distinguish that what is more perfectly intelligible can be understood by us in two ways — either simply or proportionally. For example, the eagle's vision of the sun is simply more perfect with respect to the sun than our vision with respect to a candle; and yet our vision is more perfect proportionally — that is, it has more of the nature of vision according to its proportion to the visibility of the candle than the eagle's vision has of the nature of vision with respect to the visibility of the sun. This distinction is taken from the Philosopher (*primo de partibus animalium cap. 5.*), who holds that although we have only minimal knowledge of immaterial things — which is to be understood proportionally — still that knowledge is more desirable than the great knowledge that can be had of material things, which is great in comparison with those knowables.

Furthermore, concerning Logic it must be said that just as it is last in invention, from what was said in the Logic (*Log. lib. 1. quest. 1. art. 5.*), so it appears to be simply posterior in dignity to the other disciplines. The reason is at hand: it disputes about second intentions, which are beings of reason, while the other disciplines labor about real beings. That a real being is simply more excellent than a being of reason escapes no one. Furthermore, the cause surpasses its effect in nobility, and the mistress surpasses her servant in dignity — this is the common assertion of the philosophers. Since, therefore, from what was said in the cited place, Logic is the offspring and effect of the other sciences, and their handmaid, it is not unreasonably assigned the last seat. It can, however, be said to be more excellent than the practical sciences in a qualified sense, because it is speculative — and that the speculative surpasses the practical is clear from the first assertion. Again, Logic concerns itself with the craft of the mind and judges truth from falsehood, which certainly indicates some preeminence over

mechanical works, which are produced by productive habits. Wherefore Logic excels the practical sciences in a qualified sense, just as a spiritual accident is said in a qualified sense to be nobler than material substance, and the heavens nobler than a sublunary living being.

The fourth part is handed down by Aristotle (6. *Met. cap. 1.*) and Scotus (*ibidem*) and elsewhere, who almost always subordinate the productive to the active. The reason is that action is prior in dignity to production. For action properly is a moral operation proceeding from the will; production, however, is a manual operation passing into external matter. Again, action strictly taken is spiritual, while production is material. Since, therefore, the active science expends its effort on action and the productive on production, the active is without doubt preferred to the productive. Furthermore, the active is called the medicine of the soul, and the productive the medicine of the body; the former directs the works of man, while the latter exercises itself on mechanical and other works apart from the cares of man. Hence Scotus says (*questione quarta Prol. antè DD.*) that the active, or moral science, was discovered for the sake of intrinsic necessities — that is, for moderating our passions and operations. Finally, the active science treats of the last end of man, his happiness, and his supreme good (*Diuus August. 8. Ciuit. 3.*) — which clearly demonstrates its eminence above the other sciences, especially the productive, as may be seen in the first book of our moral philosophy.

One objects, first, against the first assertion: Theology, by the common assent of all, excels the other sciences in nobility, which according to the cited Scotus is practical. Therefore the speculative does not surpass the practical. I respond: the first assertion proposed is to be understood of sciences acquired by human effort, not of sciences divinely inspired, such as Theology, which is set down by Scotus as practical. This response is derived from the same Doctor (*quest. tertia sub T. & quest. allegatâ sub BB.*), and is accepted by Orbellis, Faber, and others in that place.

You will press: it is nobler to be for one's own sake than for the sake of another, as Aristotle grants (1. *Met. 1.*) and as is admitted in the first assertion. But speculative science is for its own sake and practical science for the sake of another, from the same author. Therefore, whether science is had from nature or from God, the speculative always surpasses the practical in dignity. The major is to be distinguished, according to the cited Scotus (*CC.*): if it is for the sake of something inferior and less noble — granted; if it is for the sake of something more noble and more excellent — denied. This response is clarified and confirmed from (7. *Pol. 14.*): "It pertains to the noble to attain its own superior in an inferior being." Hence the sensitive faculty of man is nobler than the sensitive faculty of a brute, even though the latter exists for itself and is not ordered to any higher faculty, while the former exists for the sake of another — that is, is ordered to a more excellent power, namely the intellective. Similarly, that

science is to be judged nobler which tends toward a nobler act of another power than that science which stops at the intellect and goes no further. Thus Theology, tending toward practice, that is, toward love and charity toward God, which is a nobler act of the will than an act of our intellect, therefore surpasses in dignity the speculative doctrines. Aristotle, however, thinks that speculative science excels practical science because he posits no science that conforms to the practice of the will regarding the end. For he does not suppose that the will has a practice regarding the last end, but only a certain natural movement. Hence he does not judge there to be any science nobler through conformity with the end.

You will urge: if the response given is valid, Ethics would be worthier than the other sciences, because Ethics directs practice, which is an operation of the will conformable to the right dictate of the intellect, while the others remain in speculation alone — or, if they go beyond the intellect, are directed toward the affection of an external work. But from what was asserted above, Ethics holds its place after the speculative sciences. Likewise it follows that Metaphysics would be practical, since it is about God, attainable by operation — that is, visible through the vision of the intellect and lovable and enjoyable through love — which contradicts the common doctrine of the philosophers and especially the Scotist school. If perhaps the consequent of the major is granted, no inconvenience seems to follow from what was conceded. For, with Aristotle (*10. Eth.* 7.) and the saint locating happiness in the contemplation of abstract substances — and therefore admitting no practice regarding the last end — it is no wonder if he prefers the speculative to the moral and to all the practical. We, however, illuminated by the light of faith and recognizing that the last end is attainable by us through operation, especially through love and enjoyment, and that our blessedness consists most of all in the enjoyment of God, which is an operation of the will or practice — we willingly and openly maintain that the practical surpasses the speculative in the manner stated above. All the more so because what is practical in this sense is called not precisely Ethics but Theological and divine science, since it regards God as attainable through operation. To the other thing that is appended concerning Metaphysics, I say that Metaphysics considers being, God, the Angel, and the other transcendents as speculable and not as operable; therefore simply speaking Metaphysics is speculative.

You will say: the dignity of a science is derived from the excellence of its object, as I have often insisted. But the speculative participates in a nobler object than the practical — as Metaphysics has God, who is the most excellent substance, as its object, while the practical — as Ethics — has the moral act, which is an accident, as its object. And if some substance is assigned to it as object, none other will be given than the human substance, which is inferior to the substance of God and of the Angel, as no one denies. Therefore no practical science precedes speculative science. Granting the major, to the minor I say that Ethics,

as Aristotle handed it down, has for its object the human being to be imbued with good morals (*libro primo Philosophiæ Moralis, questione tertia articulo vn. assert. 3.*). But the practical science which we maintain surpasses the speculative in dignity tends toward God, the supreme good, attainable by us through vision and enjoyment. Therefore it formally and objectively excels the speculative sciences. And this science is properly to be called not Ethics but Theological science, as I forewarned above.

Question II. On the Nature of Physics.

Article I. Whether Physics Is a Science.

Aristotle (*4. Met. cap. 5. T. 22. Scot ibi, & 1. Post. quest. 1. & 1. distinct. 3. quest. 4.*), Lychetus in that place, Bargius, the Parisians (*1. Phyf. quest. 3.*), Tataret (*ibid. quest. 1.*), John of the Masters, and others, preceded by Augustine (*1. Retract. 1.*) and in three books against the Academics — recount and refute the opinion of the ancient and recent Academics who suspected that all things are ambiguous and uncertain, probable and apparent, mutable and inconstant, concerning which there is neither natural science nor any other, and that the truth of natural things is sought but not attained, lies hidden in darkness, and never comes to light. Thus the Academics appeared to be masters of ignorance rather than of science — whom the authors just named argue against most keenly, refute, defeat, and overcome, asserting that there is a science of natural things, that certain knowledge of them is acquired by us, and that truth concerning them shines upon us.

Note first, from Scotus (*in prol. quest. 5. lat. §. Sed aliud sub C.*) and to be recalled from what was said in the Logic (*Log. libro primo, quest. 2. artic. 2.*): one of the conditions required for science is that it be about a necessary object — necessity obtaining not on the side of the science, since it itself can be contingent and erased by forgetfulness, but on the side of the object. This is not to be understood with respect to existence and entity, since we have science of Man, Lion, and others which are contingent and corruptible and at times do not exist, but with respect to the objective and quidditative being — not indeed in the incomplex mode but in the complex mode, that is, according to the necessary connection and relation that the extremes have toward each other. Thus this proposition is necessary: "Man is risible," because between its predicate and subject there obtains a necessary bond. For the knowable proposition is described by Tataret and the Parisians, cited (*quest. 1.*), as: a necessary proposition naturally fitted to be made evident through necessary propositions applied to it through syllogistic discourse. Of this there are three necessary conditions: the first is that it be necessary, to exclude contingent propositions like "Man is white"; the second that it be dubitable, to exclude self-evident propositions known from the mere explanation of their terms; the third that it be generated

and rendered evident through syllogistic discourse, in distinction from the habit of principles, about which there is no science.

Note second: science is not of singulars (perhaps with the exception of Theology) but of universals, because singulars do not have properties distinct from the universals through which we might acquire science of them. Furthermore, individual material things are corruptible and temporal, while science (*1. Post. cap. 7. T. 21.*) is of incorruptibles and eternal things. Therefore, although individual natural things are subject to generation and corruption, Physics is not to be removed from the company of the sciences, since it is not concerned with them insofar as they are singulars, but with their common natures, which have properties necessarily and perpetually cohering with them; and as such, those natures are not corruptible except mediately and per accidens, as Aristotle (*1. Met. in proœm.*) holds. Insofar, that is, as their individuals are corrupted. Wherefore Scotus (*3. distinct. 22. quest. vn. §. Ad 1. argumentum sub H.*) adds that science is had about mutable, generable, and corruptible things, not in the singular but in the universal — knowing that such things are mutable, generable, and corruptible. Or, as others say, of mutable things science is given not reduplicatively but specificatively. For (*1. Post. 2.*): "Corruptible things" — supply, "reduplicatively" — "are not scientifically knowable." For a corruptible thing cannot be incorruptible, just as a mutable thing cannot be immutable, and a contingent thing necessary — as the same Doctor writes (*quest. f. lat. §. Sed aliud H.*) and Pererius objects (*lib. 2. Phys. cap. 3. in resp. 6. dub.*). For to know a contingent thing as necessary is not to know a contingent thing, and to know a mutable thing as immutable is not to know a mutable thing — as Scotus argues against Henry (*mox citatus §. Primò*); and to know a corruptible thing as incorruptible is not to know a corruptible thing. Otherwise everything would fall under science, since there is nothing that cannot be considered under that reduplicative particle "as" or "insofar as it is such" — which was amply rejected in the Logic (*Log. lib. 5. quest. 4. art. 1.*). I add that the intellect would be deceived in knowing things otherwise than they are. If, therefore, things are mutable, it knows them as mutable, and so with the rest, as they are.

Note third: although the Philosopher wrongly supposed the world to be eternal, and likewise prime matter, motion, the Intelligences, the natural necessity of God in acting, and other things of this sort — it is not on that account to be judged that Physics is in large part not a science, as Pererius thinks (*vbi supra ad 8.*). For concerning those matters, science is not had with respect to their existence but with respect to their essence as prescinding from existence, as Orbellis rightly notes (*Orbel. 7. Met. cap. 3.*); and therefore the nature of science is not taken away, whether things have existed from eternity or in time. Moreover, even we who are illuminated by the light of faith cannot for the most part demonstrate what the Philosopher perhaps did not demonstrate. Therefore it does not seem any more ours than the Philosopher's science. Although the same author mixed in some falsehoods and inserted some probable matters, science

is not thereby taken from it — just as in Logic many probable matters are treated, although Logic itself is absolutely and simply a science. For that is absolutely called a science which regards an absolutely knowable subject, of which sort the natural body is.

Assertion: Physiology is truly and properly a science. So Scotus (*quest. 3. vniuerf. in solut. 2. Et 3. dist. 22. quest. vn. §. Rationes sub D. Et distinct. 34. quest. vn. Et quest. 3. prol.*), preceded by Aristotle (*3. Phys. cap. 4. 2. Met. T. 5. & 22. Et 6. eiusdem operis cap. 1.*), who divides speculative science into Physics, Mathematics, and Metaphysics, and supported by Augustine (*Aug. 8. Ciuit. cap. 4.*), who, adducing and accepting the Platonic tripartite distribution of philosophy into moral, natural, rational, and metaphysical, adds that the moral is most engaged in action, the natural is assigned to contemplation, and the rational distinguishes true from false.

This is proved first from that vulgate division of philosophy and science, related by Augustine (*Aug. 8. Ciuit. cap. 4.*) and delivered by Plato, drawn from the Hebrews: into natural or Physics, moral or Ethics, and rational or Logic and Metaphysics. Second: about a truly knowable object, there is true science (*1. Post. 2.*). But Physics has for its object the properly knowable thing, which, as will be said in the next question, is the natural body, about which many things are demonstrated and known — some of which the Doctor adduces (*3. distinct. 22. cit.*): "Every body composed of elements is corruptible, because it is put together from contraries; but the human body is of this sort, as is clear; therefore the human body is corruptible." Likewise: "What is composed of matter and form is generable and corruptible, since the first root of corruption, as the Doctor testifies in the same place, is matter together with the privation conjoined to it, which is in potency for transmutation to another form it lacks — as the matter of air to the form of water, and vice versa. But every mixed composite is made up of matter and form; therefore every mixed composite is generable and corruptible." Third: demonstration and science are of universals (*1. Post. T. 43. Et 7. Met. T. 53.*). But Physics is about the natural body, which is universal, for it abstracts from animate and inanimate, from simple and mixed, from this and that — as I introduced universally in the preface to this work. I add that the other conditions of science adduced and explained by us in the cited Logic agree with this admirably. For Physics is certain and evident knowledge of a necessary natural thing, acquired through syllogistic discourse. And in Physics it is demonstrated no less that man is risible than in Mathematics that a triangle has three angles. For in both cases an equal reason is given — namely that from the nature of man and from the nature of a triangle there necessarily flows a proper property, and an indissoluble bond intercedes between each and its property. Finally, what Scotus adduces at length and acutely (*1. distinct. 3. citatus*) openly demonstrates the proposed assertion; and what he accumulates against the Academics (*August. post Aristot. allegatum*), at the beginning of this article, clearly and neatly convince everyone, even the obstinate — so much so that

some strive to vindicate those great men aforesaid from such great falsehood and absurdity of philosophizing, among whom is Cicero (5. *Tusc. quest.*) whose words Augustine cites (3. *contrà Academ. cap. 20.*), and with whom the same Augustine seems to agree, both there and in (8. *Ciuit. cap. 4.*). For it is said that it was their custom to conceal their opinion and not to reveal it to anyone except those who had lived with them into old age.

One objects, first: the first guides of all our intellection and scientific cognition are the senses, as the Philosopher's dictum (*lib. de sensu, & sensato cap. 1.*) indicates: "Nothing is in the intellect that was not first in the sense." But the senses frequently err and are deceived concerning sensible things — as sight judges a stick placed in water to be crooked and broken, when it is truly straight and whole; taste in a sick person judges sweet food to be bitter; and touch with fingers crossed, when one hand moves only one globe, judges there to be two globes. Therefore no certain and scientific knowledge can be had of sensible things. I respond from the Doctor in the first cited passage (§. *De tertiis*): our intellect takes its beginning of knowledge from the senses not as from a cause but as from an occasion. Therefore, even if all the senses erred, the intellect itself would not err, given certain and proper conditions regarding the proper sensible, to be explained in the book on the soul — especially because it has its terms within itself, which are the cause of truth. Thus the Doctor says in the cited place (*Sub D.*): if someone born blind had the species of whiteness and blackness impressed on him miraculously in dreams, and afterward awakening, his intellect abstracting from these could compose this proposition: "White is not black." And in this enunciation the intellect would not be deceived, even though the terms were not received from a senses that erred — because the formal nature of the terms, to which one has arrived, is the necessary cause of truth of the aforesaid negative proposition. Wherefore the intellect cannot go astray, relying on that universal affirmative proposition which is true from a necessary and natural cause duly applied and not impeded: "A necessary and natural effect flows" (2. *Phyf. T. 48.*). Hence, to the instance about the stick which appears oblique and broken in water, I say that the intellect is confirmed and certified by this evident proposition: "Nothing harder is broken on contact with something soft that yields to it." But that the stick is harder than water, and that water yields to it, is plainly known both by sight and touch — and so it is plainly clear to the intellect that the stick is not broken, as sight judges. To the other instance I say that it arises from the indisposition of taste, which, affected by a bitter humor, judges sweet food to be bitter. More will be said in its proper place.

One objects, second: science is about an object that is known, determinate, and necessary (1. *Post. 2.*). But Physics concerns itself with something unknown, indeterminate, and contingent — namely prime matter, which is unknown (7. *Met. 35.*), indifferent to receiving all forms, and contingent, since, as is stated in the same place (*T. 22.*), matter is that by which a thing can be or not be.

Therefore Physics is not counted among the sciences. This reasoning is one of the principal ones by which the aforesaid philosophers, who did not distinguish potency from act, existence from essence, and singular from universal, openly confessed themselves overcome. I grant the major, I deny the minor. To its proof, which is supported by the testimony of Aristotle, the Doctor responds (*in expositione illius tex. & 3. distinct. 22. quest. vn. §. Ad 1. argumentum sub H.*): matter is said to be unknown because form is in some way the reason for knowing matter itself. Or you may say that the Philosopher is speaking of matter taken for the individual difference, which is not known by scientific knowledge, as the same Doctor notes in the same place.

One objects, third: about mutable and inconstant things, and about temporal and fleeting things, science is not generated (*1. Post. 2. 7.*). But Physics contemplates mutable and variable things — such as the elements and things compounded from them, which undergo constant mutation; it also considers durable and mobile things — the motions of the heavens, the risings and settings of the stars, the eclipses of the sun and moon, the perpetual generation and corruption of sublunary things, the life and death of living beings, and other matters treated in the course of Physiology. Therefore Physics is not to be numbered among the sciences. This is the other fundamental argument of the aforesaid authors, who, perceiving that nothing under the sun is firm, that no degree of created being is fixed, and that everything is stirred by restless motion — acquired and lost by sensible and mobile things — judged that all certainty and truth was to be eliminated. I distinguish the major: in the incomplex mode and in the being of existence — granted; in the complex mode and in the being of essence — denied. The authority of the cited Aristotle is thus expounded. For mutability and corruptibility are properties of mutable and corruptible things, just as visibility is a property of color, as Scotus holds (*in tertio citato sub G.*). For just as this is true and in the second mode of per se predication: "Color is visible" — so these are true and in the second mode of per se predication: "Man is corruptible," "The heaven is mobile," and "The moon is eclipsable," since between the extremes of these propositions there obtains a perpetual and necessary connection. For the intellect can apprehend simple terms, then compose them with each other, come to know the property emerging from the subject, and from premises that are true and necessary deduce conclusions that are true and necessary — as the Doctor shows in the same place. I add with the same author (*1. distinct. 3. quest. 4. 9. De tertiis circa H.*): "Although the object is corruptible and mutable, it is nevertheless immutable from a true entity into a false one."

Article II. Whether Physics Is Speculative.

What I treated at length in the Logic is to be recalled (*Log. lib. 1. quest. 2. art. 5. Et lib. 5. quest. 4. artic. 4. 5. 6.*).

Assertion: natural philosophy is speculative. Defended by Aristotle (*6. Met. cap. 1. T. 2. Et 11. eiusdem operis, cap. 2.*), Scotus in the same place and (*3. distinct. 34. quest.*

vn. D.), Orbellis (6. *Met. cap. 1.*), Anthony Andrew in that place, the Parisians (1. *Phys. quest. 2.*), Tataret (*quest. 1. scibili 2.*), and others, who with one voice approve and confirm the division of speculative science into Mathematics, Physics, and Metaphysics — supported by Augustine (*Aug. 8. Ciuit. cap. 4.*), who, adducing and accepting the Platonic tripartite distribution of philosophy into moral, natural, and rational, adds that the moral is most engaged in action, the natural is assigned to contemplation, and the rational distinguishes true from false. That science is speculative which regards a speculable object, and practical which has an operable object, from what was asserted in the Logic (*Log. lib. 5. quest. 4. art. 5. O 6.*). But Physics contemplates the natural body, which by Aristotle (6. *Met. cap. 1.*) is one of the three contemplative objects. For we have science of those things about which we have neither art nor choice. Third: every science is either speculative or practical, since between the two there is no middle ground, either through participation in the extremes or through negation of them — as I proved at length in the place just cited (*art. 4.*). But Physics is not practical, since it is not active or moral, nor productive or manual. Therefore it is to be numbered among the speculative sciences.

One objects, first: Aristotle (1. *de partibus animalium cap. 2.*) seems to expunge Physics from the theoretical sciences, saying that the mode of demonstrating and the ratio of certainty in Physics are different from those found in the speculative sciences. Therefore, in the Peripatetic doctrine, Physics has no place among the speculative sciences. I respond: the Philosopher there only intends that Physics does not enjoy a mode of demonstrating as easy and evident as the mathematical disciplines possess — which he is openly speaking about in that place. The reason given is that the latter contemplates things mixed with matter, for the acquisition of which we need long experience, while the mathematical disciplines abstract from sensible matter, for the acquisition of which, on account of their manifest certainty and evidence, experience does not seem to be necessary. Therefore they are said to take on a more speculative mode. Wherefore Aristotle nowhere denies that Physics is speculative; rather he expressly affirms it, as is clear from his testimonies already cited in support of our proposed assertion.

One objects, second: Physics tends and is ordered toward practice; therefore it is practical. The consequent holds. The antecedent is proved: from physical and sensible things we are raised to knowledge of the first cause, namely God, and to love of him — as, after the Doctor of the Gentiles (*Rom. 1.*), Augustine plainly teaches (1. *Retract. 6. Et difertè 2. de ordine. Et in soliloq.*). For the human being, desirous of the good and the beautiful, is supremely captivated and delighted by the greatness, goodness, and beauty of sensible and visible things, and from knowledge and love of them he is undoubtedly stirred and provoked to know and love God, their Maker and Author. Hence the same Paul rightly reproaches the pagan philosophers for having failed to glorify God as they knew him. I deny the antecedent. To its proof I distinguish: *per se* — denied; *per accidens* —

granted. For the end of Physics is not practice, nor is its object practical, but the speculation of natural things is its proximate end, and the natural body is its speculable object. Wherefore it is per accidens that someone might be raised from the appearance and form of sensible things to love for their Creator — just as it also happens to Metaphysics, if someone, from its predicates that are transcendent and divine attributes, is moved to love God and the Angels.

You will insist: that part of Physics which treats of how clouds, rain, snow, hail, and other meteors are formed in the middle region of the air does not seem to be excluded from the number of the practical sciences; and that which concerns human operations is no less practical than the part of Ethics which labors about those same operations. Therefore Physics is not entirely speculative. I say that Physics speculates on the proper natures, quiddities, and formalities of the aforesaid things; the making of them is accidental to it, and it does not rest in it of itself — just as Astrology does not rest in the making of an astrolabe, Geometry in the forming of a triangle, and Logic in the construction of a syllogism. Such works do not exclude the aforesaid sciences from the company of the speculative disciplines, since they are accidental to them.

One objects, third: Medicine is practical; therefore Physics is too. The consequent holds, for the former is a part of the latter, since it considers the human body, which is contained under the natural body as one of its species. The antecedent, besides being Scotus (*quest. 4. prol. §. Ad rationes oppositas. FF.*), is urged: Medicine expends its effort on curing sick bodies, on the laws of healing and antidotes; it strives to introduce and preserve health in those same bodies — which is suited to a practical habit. I grant the antecedent, I deny the consequent. For they are distinct sciences possessing distinct formal objects, since Physics speculates on the natural body under the formal notion of naturalness, which is speculable, while Medicine inspects the natural body under the formal notion of healability, which is the distinct formal practical notion from naturalness. Hence the former is aptly placed among the speculative sciences and the latter among the practical. Although the common run of physicians distinguishes Medicine into theoretical — which discourses about the universal causes and cures that are more remote from practice — and practical — which treats of particular cures that are proximately and immediately conformed to practice — and this latter is entirely practical while the former, though relatively called speculative, is nonetheless simply practical. The reason for this is given by the Doctor in the cited first place: because it virtually includes the said particular mode, formally and proximately conformed. Nor does it escape me that Aristotle (*l. de sensu, & sensibili cap. 1.*) calls Physics and Medicine sisters — perhaps for no other reason than on account of the affinity and similarity they have toward each other, which seems to lie in the fact that each heals, though in different ways, as is stated by the same author. For Medicine prepares remedies for the body, while Physics applies healing to the soul. For all Philosophy can be called the medicine of the soul, as Pererius notes above all

others (*Perer. 1. Phys. cap. 2. cit. à Ferch. vestig. 9. cap. 2. num. 7.*). There are moreover two diseases of the soul: disease of the intellect, and disease of the will. The former is ignorance of truth, which is removed by speculative philosophy; the latter is corruption of morals, which is taken away by practical philosophy, or Ethics. Finally, since Physics and Medicine occupy themselves about the same material object — the natural body — and since the latter borrows much from the former and frequently puts on its character, the Philosopher not unfittingly named them sisters.

Article III. Whether Physics Is One Science.

Henry (*Henr. Quol. 9. quest. 4.*), Cajetan with Thomas (*Caiet. Tract. de subiecto Philosophia naturalis, 12. quest. 54. art. 4.*), Ferrariensis (*Ferr. 1. contra Gentes*), and not a few recent thinkers — particularly Ruuius (*Ruuius in proæm. Physic.*) — affirm that Physics is one simple quality that extends to all the parts considered in it. Or, as some prefer, that it is one most simple quality which is wholly generated at the first physical demonstration, as regards intention, and afterward extends to other scientific conclusions through other demonstrations to be constructed — or is increased as regards extension, with no new entity and no new degree accruing to it — just as one and the same heat, extended through various parts of the body, receives no new entity or degree of intensity. Some thinkers, whom Soncinas mentions (*6. Met. quest. 9.*), judge it to be a simple quality but explain it differently from the authors just cited. For they say: just as from many heterogeneous parts — head, arms, and so on — one body is constituted insofar as they agree in one matter and form, so all the partial habits of Physics, generated through individual demonstrations — though they differ among themselves in species, since they are concerned with specifically distinct subjects such as heaven, earth, and the like — nonetheless, insofar as they agree in a kind of one form of science, which is the formal notion of the object, namely naturalness or mobility, are said to constitute one simple quality. The rest, however, think that Physics is a quality composed of partial entities truly united among themselves, since without any addition there can be no true augmentation, and without true union there can be no unity of a habit. The Nominalists — Ockham (*in prol. q. 9.*), Gabriel (*ibidem quest. 8.*), and Gregory (*quest. 3. artic. 1.*) — hold that any science acquired by the powers of nature is one by aggregation. Cited in support of this opinion are Scotus (*quest. 3. Prol.*), Anthony Andrew, and the entire Subtle school — though these do not teach that Physics and any other science is one by aggregation but one by the unity of a remote genus, as may be seen in Anthony Andrew (*6. Metaphysicæ, questione 3. articul. 1.*), Tataré (*hoc loco, questione proæmiali, dubio 2.*), and Scotus (*text. citat. & 6. Metaphysica, quest. 1.*).

Note, from the cited Scotus and to be recalled from what was said in the Logic (*Log. l. 1. quest. 2. artic. 4.*), that the unity of a science is twofold — intrinsic and extrinsic. Intrinsic unity is that which follows on the entity and essence of the

science, since every being is one, given that unity is a property of being, as will be said elsewhere. The extrinsic unity of a science is derived from the object it regards. And therefore, if the object is one in species, the science about it is one in species; if it is one in number, the science is likewise one in number; if it is one in genus, the science is equally one in genus. Hence arises the distinction of science into formal, virtual, and potential. Formal science is knowledge of a particular demonstrated conclusion — whether the demonstration be proper quid or quia — inclining the intellect precisely toward speculation of that conclusion. Virtual science is knowledge of the first or adequate subject that contains virtually within itself all the knowable conclusions demonstrable about such a subject, inclining formally toward its speculation and virtually toward knowledge of all those things that are virtually included in it — which happens when the subject is specific. Potential science is knowledge of the subject and of all those things that are potentially enclosed in it — and this occurs when the subject is generic, potentially containing its species. Wherefore a science can be called one in number, or in species, or in proximate or remote genus, as Anthony Andrew rightly notes in the prenominated place. What, moreover, is and how many kinds there are of containment, and the rest of what makes for a full understanding of this difficulty — all these are to be reviewed in the Logic (*Log. libro 5. quest. 2. artic. 8. notat. 1. indè*).

Assertion I: Physics is not one simple quality generated at the first demonstration as regards intention and afterward increased as regards extension through the other demonstrations. Deduced from Scotus in the cited places, near the beginning of the article. This is proved first: the same reason holds for one demonstration as for all the others. Therefore, if the intellect acquires a new science through the first demonstration, it will also receive a new science through the second and third. But according to the Adversaries, through the first demonstration it receives a new scientific cognition; therefore through the subsequent ones as well. The antecedent is clear because a demonstration — whether first, second, or third — is the natural instrument of knowing. If, therefore, the first demonstration generates science, equally, with no obstacle interposed, science is generated through the second and third. Second: granted that opinion of the Thomists, whoever lost the first demonstration would also lose all the science acquired through the other demonstrations, since he would have acquired it all through the prior demonstration according to the aforesaid authors. But this conflicts with experience. For he who forgets the modes of demonstrating of the first figure and what is taught in the Analytics does not thereby consign to oblivion the modes of arguing of the second and third figures and what is delivered in the Topics and the Sophistical Refutations, since the latter do not depend on the former in the least. Third: in the opinion of the said Thomists, acts naturally generate habits by this — that they naturally leave their likeness in what receives them. But of agents specifically different there are real likenesses specifically distinct — just as acts specifically diverse are, such as

the intellections of diverse principles and diverse conclusions, about which one does not have the same specific habit. Fourth: where the cause is the same, the effect is also the same. But moral objects and acts specifically different — such as those of temperance and justice — generate habits specifically diverse, because they impress specifically different natural likenesses on the faculty according to their proper specific natures. Therefore in no way is the whole of Physics acquired by a single demonstration.

Assertion II: Physics is not one thing constituted from various degrees of the same species. This follows from the principles of Scotus and is opposed to some recent thinkers. This is proved first: things of diverse species cannot constitute one thing in species, as is clear from the terms. But cognitions, or scientific acts, about specifically diverse objects are of diverse species, just as their objects differ in species. Therefore from the said acts diverse in species, one science in species is not coalesced. Second: granted that opinion, there would be no generic science, but all sciences would be specific — which contradicts (*1. Post. T. 43.*): "One science is of one genus of subject." Therefore Physics is not one science constituted from many degrees of the same species.

Assertion III: Physics is not one by aggregation, nor one by the unity of order, in the manner in which a house or a ship is said to be one. This is gathered from the Doctor in the cited passage. The first part is proved: first, things aggregated into one are beings per accidens, like a heap of grain and a pile of stones, which do not fall under science (*6. Metaphysica, T. 5.*), since science resides per se in the category of quality, as is clear in the Epitome (*libro 1. quest. 4. art. 7. in fine*). Therefore science is not to be reduced to things that are one by aggregation. Second, science is about a conclusion, and it is said to be the effect of demonstration proceeding per se from principles and causes — as I showed at length from Aristotle (*1. Post.*) in the Logic (*leg. 5. quest. 3.*). I add that the subject of science, which potentially or virtually contains all its scientifically knowable truths, is one per se — since it is a species or genus, which everyone denies to be a per accidens being. Therefore Physics, which is concerned with the natural body as its subject — which is a subalternate genus, as may be seen in the tree of Porphyry adduced in the Epitome (*libro 1. quest. 3. artic. 4. num. 6.*) — is not one by the unity of aggregation, whatever Ponce may say (*disp. 30. quest. 2. concl. 4.*).

The second part is proved: first, things that are one by order are of diverse genus and species, as is clear from the World — which, since it has unity of order as Aristotle (*12. Metaphysica, T. 51.*) and Scotus affirm (*lib. de primo principio cap. 3.*); following Pythagoras, who delivers the World to be the totality of all things, it contains all the genera and species of diverse things. But Physics is of one genus only, namely the category of quality. Therefore it is not one by order. Second, things that participate in unity of order agree only in a relation, because order is a relation, from Scotus (*2. diff. 1. quest. 4.*): for it is the relation of equals and unequals. But Physics, being a science, is of the genus of quality, which is an

absolute being. Therefore it is not to be judged one by order. Third: a relation, such as order, is not per se caused but results from the posited terms, as has been said elsewhere. But Physics is per se caused from principles — for it is the effect of demonstration (2. *Post. cap.* 2.) and the terminus of the action of the intellect (9. *Met. T.* 16.). Therefore Physics is not constituted one by unity of order.

Assertion IV: natural philosophy taken universally is one by the unity of a remote genus. This is thus deduced from the same Doctor in the same place. This is proved first from (1. *Post. T.* 43.): "One science is of one genus of subject." And (4. *Met.*), cited by the Doctor (*quest.* 2. *primi Priorum*): "Just as one sense is of one genus of the sensible, so one science is of one genus of the knowable, that is, of the subject." The same is gathered from (1. *Post.* 2.) and from (3. *de anima T.* 51.): "If the sciences are cut just as the things they are concerned with, and from the same things their unity is derived — therefore for the diversity of things there is a diversity of sciences, and in accordance with their unity the same unity is fittingly derived." But many things in Physics differ in species and agree in the same genus. For, as will be shown in the next question, the natural body is set down as the total object of Physics — and this is a genus with respect to simple and mixed body, animate and inanimate. Therefore natural philosophy, which treats of all these, is one in genus.

One objects, first: the habits of the will — such as virtues and vices — are referred among simple qualities, though they labor over diverse objects (as temperance about food and drink). Therefore the same is to be said of the habits of the intellect, in whose number Physics is found. The antecedent is to be denied. For, as the Doctor says (3. *distinct.* 34. *quest.* 1.), temperance is not one in species. For there can be as many distinct pleasures as the will can repress, and as many species of temperance that moderates them — whether regarding gustables or tangibles, or not only regarding sensibles in which the will conjoined to them takes delight, but also regarding insensibles and what is properly its own, in which the will taken precisely finds its pleasure.

One objects, second: there is no stronger reason why several lights should mix with one another and constitute one simple light, and why many degrees of heat should coalesce into one perfect and intense heat, than why several demonstrations — which are lights of the intellect — should constitute one simple and perfect specific science. Therefore nothing prevents all the demonstrations of Physics from coming together in one and making one specific science. I deny the parity. The reason is that lights and degrees of heat are of the same species and are not caused by specifically diverse objects. But the partial habits of Physics differ in species among themselves and are generated by partial specific objects — therefore the former coalesce into one in species, but not the latter.

Article IV. Whether Physics Is a Subalternate Science.

Some thinkers hold that all the other sciences are subalternated to Metaphysics, cited by Fonseca (*Font 4. Met. quest. 2. cap. 1.*) and Suárez (*Suarez disp. 1. Met. Sect. 5. numero 45.*) — to whom the Complutenses most recently adhere (*Complut. quest. 2. Proæmiali*). Others, whom Pererius mentions (*Perer. lib. 2. cap. 4.*), affirm that Medicine is subalternated to Physics and Physics to Metaphysics. Nor are there those lacking who think that Logic and Ethics are subalternated to Physics. The common opinion, however, is that of the other philosophers who deny the aforesaid subalternations of the sciences.

Note first, and recall from what was said in the Logic (*Log. lib. 5. quest. 4. artic. 7.*), what subalternation is and how many kinds it has, and what conditions are required for it properly taken. For, first, true subalternation of sciences requires that the object of the subalternated be contained under the object of the subalternating — for lack of which Medicine is not subalternated to Geometry, because the healable body, which is the object of Medicine, is not comprehended under the line, which is the object of Geometry. Second, that the subject of the subalternated add an accidental difference — for which reason the science of the species is not subalternated to the science of the genus, since though the species is under the genus, it adds above it not an accidental but an essential difference. For this reason Anthony Andrew (*1. Met. questione prima ad f. Post.*) and Scotus (*ibidem, quest. 9.*) note that those who set down mobile being taken for a property of the natural body as the object of Physics cannot avoid establishing Physics as subalternated to Metaphysics, since mobility is as it were its accidental difference. Third, that the principles of the subalternated are conclusions proved and demonstrated in the subalternating — as is clear from *Perspectiva*, which proves that things are seen smaller from a distance than if they were nearby, through this principle: that a triangle with two larger sides makes two smaller angles at the base, and the one at the point is smaller — that is, those two lines touching the seen object make a smaller angle in the seen object the more remote it is, and a larger one the closer it is, as may be seen in this figure. This principle is a conclusion in Geometry, where it is demonstrated; in *Perspectiva*, however, it is not proved but presupposed as a proved truth.

Note second, from Trombet (*Tromb. quest. 6. Met.*), that one science may be subalternated to another in two ways. First, through extrinsic denomination — that is, with respect to the subject that denominates the subalternated science extrinsically. Second, through intrinsic denomination — which happens when one science is by its own nature subjected to another, just as the less common is to the more common. Nor should it be passed over, from Scotus (*in Prol. quest. 4. principali, & f. laterali §. Ad 2. quest. dico sub E.*), that although the same proposition can be considered by two sciences in different modes — that is, by one more clearly and by the other more obscurely — nevertheless between them there falls no proper subalternation. Thus, although Metaphysics knows the quiddity of a line more distinctly and perfectly than Geometry, Geometry is not subalternated to it on that account. For both of them are deficient in the

proper conditions of subalternation set out above. Hence, for the same reason, although Metaphysics proves and confirms the principles of the other sciences and sees more clearly the quiddities and essences of things in common, the other sciences are not thereby subalternated to Metaphysics itself.

Assertion I: Medicine is not subalternated to natural philosophy. This is proved first from Scotus, who (*quest. 4. Prol. §. Ad rationes pro opinione opposita AA.*) writes that all Medicine is practical-productive. And (*6. Met. quest. 1.*) he had previously stated that Physics is speculative. But the practical is not subalternated to the speculative, because according to the same Doctor now cited in the first place they differ essentially. Therefore in Physics and Medicine there falls no true subalternation. Second: the formal objects of both the aforesaid sciences are formally and essentially diverse. For Medicine does not speculate on the principles, causes, and properties of the natural body; rather it tends toward production — that is, it is ordered toward the natural body as healable. Physics, however, contemplates the essence, causes, properties, and species of the natural body without any respect and order to production or action. Therefore, since their objects do not possess merely an accidental distinction, as proper subalternation requires, it is plainly deduced that the aforesaid disciplines do not undergo true subalternation.

Assertion II: Logic and Ethics are not subalternated to Physics. This is gathered from the principles of Scotus in the cited passage. This is proved: proper subalternation requires the same essential subject in subalternate sciences, only accidentally distinct in the subalternated, from what was noted above. But the three enumerated sciences possess three subjects formally and essentially distinct from one another. For Physics contemplates the natural body as natural; Logic the syllogism as such; and Ethics regards the human being to be imbued with good morals, as Scotus agrees (*questione tertia, prol. f.*). Again: real being is not accidentally contracted by rational being, and vice versa — since being is equivocal to real being and being of reason, as the Formalists demonstrate (*Traetus Formalitatum*). But the syllogism is a being of reason, while the objects of the other sciences are real beings. Furthermore, natural being presupposes artificial and moral being, as is clear (*Quol. 18.*). Between these no one doubts there to be an essential distinction. Moreover, the conclusions of Physics do not seem to be principles of Dialectic or of Ethics — as they would be if they were subalternate. Therefore the aforesaid sciences are immune from subalternation.

Assertion III: Physics is not subalternated to Metaphysics. Deduced from the Doctor (*questione tertia prol. §. Ad 1. argum. 2. quest. T.*), which is expressly held by Trombet (*Tromb. vbi supra*) and Canonicus (*Canonic. 1. Phys. quest. 1. art. 2.*). This is proved first, by the absence of the conditions required for true subalternation of the sciences, which are contained in the three-part number given above and already explained — and indeed the first condition is lacking to the said sciences, since they enjoy distinct essential subjects, of which one is being,

proper to Metaphysics, and the other the natural body, adapted to Physics. The second is also lacking: because the subject of Physics is contracted not by an accidental but by an essential difference, which is naturalness. Nor is the third found: since Physics enjoys its own per se and self-evident principles, independent of Metaphysics — such as "there are many beings," "motion exists," "nature is given," and the like, which do not depend on Metaphysics. Second, noting Scotus in the cited passage (§. *Sed quid*): one who has a subalternated science is not truly knowing unless he knows how to resolve his conclusions into the principles of the subalternating, which are immediate and indemonstrable. But it is clear that Physics has its own proper and immediate principles independent of Metaphysics. Therefore the former is not subalternated to the latter.

One objects, first, against the first assertion: Aristotle, almost at the beginning of the book *On Sense and the Sensible*, affirms that Physics knows the first principles of health and sickness, and brings forward that vulgate saying: "Where Medicine ends, Physics begins" — which the Doctor cited asserts to be proper to subalternate sciences. All the more so since the human body, which is the subject of Medicine, is comprehended under the natural body, which is the subject of Physics, and is contracted by the accidental difference which is healability. Therefore it is not to be denied that Medicine and Physics are subalternate. Pererius, cited above, although he agrees with us that there is no subalternation of Medicine in comparison with Physics, nevertheless notes that the Medicine which concerns itself with universals altogether coincides with Physics. But that Medicine which labors about singulars — the exercise and experience which the same author calls practical — says it is a habit diverse from Physics, and therefore that it is not subalternated to it. But this author is to be heard — since Medicine and Physics are distinct sciences enjoying distinct essential objects. And if only the use, practice, and experience of medical matters pertained to Medicine — what he calls practical — Medicine itself would be an art and faculty; indeed it would not formally be an art, because use is formally an extrinsic accruing relation, as I affirmed in a similar case (*Log. libro primo, quest. 2. art. 3. dub. 2.*). Again, all Medicine is simply practical, inasmuch as it is wholly directed toward inducing health into a sick body — which is an external productive work, of which the Doctor speaks (*questione quarta prol. §. Ad rationes, pro opposita sub EE.*). Furthermore, Medicine enjoys its own laws and demonstrations and principles distinct from those of Physics. I add that although Physics opens the first causes of health and sickness, it nevertheless does not treat of them insofar as they are capable of health and sickness, but insofar as they are natural things — and thus the species remains distinct from it. And so I respond, by admitting everything that is adduced from Aristotle — since it does not harm us. For those general and universal principles of Physics, being like the principles of Metaphysics adapted to the other disciplines and presupposed in them rather than proved in them, do not cause the other

sciences to be subalternated to Metaphysics, as I maintained above. Again, "where Metaphysics ends, Theology begins" — yet neither is subalternate, as the Doctor intimates (*vbi supra*, §. *Si obiiciatur*). To the other thing appended: I deny that healability is an accidental difference of the natural body, as I made plain in the foregoing.

One objects, second, against the third assertion: that science to which others are subalternated is the one which can demonstrate and confirm the subjects of those doctrines. But Metaphysics can show and strengthen the subject of Physics. Therefore Metaphysics subalternates Physics to itself. The major seems evident. The minor is urged from (1. *Post.* 8.), (1. *Phyf.* 1.), and (4. *Met.* 3.), where the Philosopher and his commentators affirm that Metaphysics supplies principles to the other disciplines, proving and corroborating them. Hence from the same Philosopher Orbellis adds (1. *Met.* 3.): all sciences are ordered to Metaphysics; indeed, that they are openly subalternated to it is delivered by Themistius, Simplicius, and many others, among whom Aquinas is cited (*Opusc. de natura generis cap. 4.*). It is confirmed: the first cause is considered by Metaphysics, in which the effect of all things is virtually contained; and Metaphysics itself can prove that the first cause exists. Therefore it will be able to prove that every effect of any thing is virtually comprehended in the first cause. I respond: the major can be conceded of improper and qualified subalternation, but not of proper and simple subalternation, which above all requires an accidental difference added above the object of the subalternating. But the objects of the other sciences participate in a formal and essential rational distinction, of the kind that cannot fall upon being, which is the object of Metaphysics — especially in the doctrine of Scotus, who divides being not into differences but into modes (1. *distinct.* 8. *quest.* 3. *N.*). Furthermore, Metaphysics does not demonstrate the objects of the other sciences by ostensive demonstration, but only by demonstration leading to the impossible — which is indirect and oblique demonstration, as is clear in the Epitome (*libro tertio, quest.* 1. *artic.* II.). Moreover, every other science apart from Metaphysics enjoys its own per se known principles independent of Metaphysics. Therefore it is not properly subalternated to it, since the subalternated borrows its principles from the subalternating, and these are the conclusions of the latter — so that a conclusion in Physics would be a true principle in Metaphysics, which the Doctor introduced as an inconvenience (*in Rep. quest.* 4. *prol.*). To the confirmation: I deny that Metaphysics treats of God insofar as he is the cause of natural effects as such, but precisely insofar as they are beings — and therefore no proper subalternation is to be introduced between the said sciences.

Question III. On the Object of Physics.

Concerning the subject of Physics, the philosophers go off into various and divergent opinions, which are touched on concisely and refuted by Bonetus (*Bonet.* 1. *Phyf. cap.* 1.) and treated at length by our two recent Scotists in the

preliminary question about the whole of philosophy. I select the more celebrated ones to be briefly and diligently examined, as best I can, in the following articles.

Article I. Whether Mobile Being or the Mobile Body Is the Adequate Object of Physics.

That mobile being is the total subject of Physics is asserted by Thomas (*Th. 1. Phys. in proœmio*) and Metaphysics (*Met. & indè*). But (*1. Cæli lect. s.*) he decrees that the adequate object of the same Physics is the mobile body. Hence the Thomists are divided among themselves. Some of them — such as Pomponatius — say that Thomas, when he was young, held in the cited place of Physics I that the object of physiology is mobile being; and then, having grown older, changed his opinion in the cited passage on the heavens and decreed that the object of this science is the mobile body. The older Thomists, however, as Javellus testifies (*1. Phys. quest. 1.*), think that Thomas' mind absolutely was to set down mobile being, and not the mobile body, as the object of that discipline. So think Cajetan (*Caiet. Tract. de subiecto Philosophiæ naturalis*), Fonseca (*Fons. 2. Met. cap. 3. quest. f. felt. 2.*), and the Coimbrans (*Conimb. quest. 4. art. 1.*). Albert (*Albert. Trait. 1. cap. 3.*), Avicenna (*Auic. cap. 1. suæ sufficientiæ*), Aegidius, and the man from Lincoln, however, judge the adequate object of Physics to be the mobile body — from whom some say the Angelic Doctor does not diverge, citing him (*1. p. quest. 84. art. 1. & quest. 14. de veritate art. 8. ad 18.*). But whatever may be the mind of Thomas, and whatever is to be replied to the proposed difficulty, his disciples may see to it. We, however, hold it as certain that the Subtle Doctor and his followers to be cited below do not place mobile being or the mobile body as the object of this discipline.

Note first, and recall from what was said in the Logic (*lib. 1. Log. quest. 1. art. 1.*), the multiple acceptations, divisions, descriptions, and conditions pertaining to the formal and adequate object of a science — as well as what I maintained (*lib. 5. eiusdem operis, quest. 2. artic. 8.*) about the containment of the subject and its multiplicity, shown and declared there at length. Presupposing and taking all this as pre-known, the material and formal object of this doctrine is investigated in the present question — although Aversa (*quest. 2. de obiecto Philosophiæ sect. 4.*) neither adverts to nor admits any formal objective notion restricting the material object of Physics.

Note second: in the view of most philosophers, mobile being, natural being, the mobile body, corporeal substance, and the natural body are taken confusedly and interchangeably (*Hurt. in proœm. Phys. Fuentem diff. 1. art. 1. Et Conimbr. quest. 4. art. 1.*). Therefore the same cited authors suspect that this is a dispute more about name and mode of speaking than about the thing itself. This seems to have a foundation in the doctrine of Aristotle, who (*2. Met. T. 1. & 6. eiusdem cap. 1.*) designates mobile being as what is considered by Physics, but (*1. Cæli 1.*) indicates that Physics labors about the mobile body. In this way those

philosophers judge they can call all others into agreement. Nevertheless these thinkers certainly do not achieve their intention. For both Thomas and Javellus and others of the same school are unwilling to come into that agreement, establishing a distinction between mobile being and the mobile body, repelling the latter and accepting the former as the proper and adequate object of Physics, as I made clear before the first note. And Fuentes (*Fuent. citat. art. 1. & 2.*) observes this. Indeed, mobile being is something more common and abstract than the mobile or natural body — for an Angel is mobile and is incorporeal. Being, however, can be taken in two ways: in one way transcendently, and thus it is broader than body and anything else predicamental; in another way particularly, that is, for physical being, which seems to coincide with the natural body, as the Philosopher intimates (*3. Phyf. T. 15.*): "Motion is the act of a being in potency, as in potency." Where being is not taken transcendently — otherwise that definition of motion would be defective, because it would be assigned through a remote genus, which is rejected (*6. Top. cap. 1. loco 27.*). And the same place of Physics states: "Motion is the act of that being which is partly in act and partly in potency, and motion is the act of that being not from the side on which it is act but from the side on which it is potency." For this reason it pronounces that axiom: "Those are physical beings which, being moved, move." Because they are partly in act and partly in potency. From these things it is well inferred against Ruuius and the Coimbrans cited — Scotists reproaching Thomists for decreeing the object of Physics to be mobile being in its whole breadth, prescinding from body and accident. For in this way a being per accidens and a transcendent being would constitute the object of Physics, which is shown to be false by what has so far been maintained and pursued at length by Faber (*Faber Theor. 20. cap. 3.*). Furthermore it is rightly deduced against Pererius (*Perer. libro primo de communibus rerum naturalium principiis*) that it is not unreasonably that Scotists attack Thomists — not because those Thomists themselves accept mobile being for mobility, which is a property of the mobile body, but for the internal principle of motion, which is the mobile and natural body — since the aforesaid Thomists, namely the cited Cajetan and Javellus, are unwilling in any way that mobile being and the mobile and natural body coincide. These thinkers, therefore, should not be dragged unwilling into common ground and a verbal dispute, as the cited recent authors frequently do, mollifying both schools. Moreover, genuine and distinguished philosophers — such as the Thomists and Scotists opposing the Nominalists, to whom not infrequently these modern thinkers favor and adhere — disdain to contend, when the matter is established, about a word and mode of speaking (*Aug. 1. Mufica 2.*).

Note third, from Aristotle (*2. Phyf. c. 1. T. 4.*): a natural being is one that consists of matter and form — of which sort the natural body is, as Tataret notes (*1. phyf. q. vn. proæmiali, not. 1.*). Body is moreover set down as twofold — physical and mathematical — as is gathered from the Doctor (*4. d. 11. q. 1. & d. 49. q. 16.*) — against Ruuius, the Coimbrans (*cit.*), and Pererius (*1. 2. c. 3.*) who add a third,

which they call the metaphysical body. Primarily, Aristotle (*3. Met. T. 17.*) enumerates only those two — from whom Averroes does not depart (*3. phys. com. 4. c.*), saying that there are two genera of bodies: one intelligible or mathematical, which is triple dimension; and another sensible or physical, which coalesces from matter and form. Nor does it help to say that Aristotle is speaking of bodies that really exist and fall under our senses, not of those that are apprehended by thought and abstracted from accidents — of which sort the metaphysical body is. For, apart from the fact that Aristotle would be defective in nowhere mentioning a metaphysical body, his division would also be insufficient. If such a metaphysical body is not real but fictioned by thought alone, it does not constitute a third body distinct from those two — just as imaginary substance and a being of reason do not make another category distinct from the genus of substance — so much so that it would be true to say: there are two genera of substance, one of real substance and another of rational substance. Furthermore, body is either intelligible and is mathematical, or sensible and is physical. To say, however, that there is a body abstracted, not compounded from matter and form, separated from motion and from sensible qualities — that does not savor of truth, since a true body is real, composed from matter and form. What consists of matter and form is mobile and sensible. Therefore body cannot be segregated from those accidents and sensible properties, at least radically.

You will say that the metaphysical body is indeed real, composed from matter and form, but is considered by Metaphysics insofar as it precedes sensible accidents in the order of nature and is examined as prescinded from them — though having a relation and propension toward them as their subject. But this does not satisfy in the least — since from that alone it is only argued for a diverse respect and differing consideration of the same body, as I said (*in Log. l. 2. q. 1. art. 4. & 6.*) about the common nature in itself and as it is abstracted and compared to its inferiors — not for any true and real distinction and diversity of body, by which a third body would be made distinct from the two previously narrated. Body, moreover, is placed in the category of substance not because its consideration pertains to Metaphysics, but in order to show the distinction and ordering of things — which is the task of Metaphysics. Or it can be said that Metaphysics considers body not precisely as body but as being and in terms of its common and transcendent predicates. Furthermore, that tripartite division of speculative science into Mathematics, Metaphysics, and Physics is derived from the three speculable objects: for Metaphysics concerns itself with being as being; Mathematics with body affected by quantity; and Physics with the natural body. But if another body distinct from these two is conceded, either a fourth speculative science distinct from the said three will be given, or Metaphysics will treat of body — which goes beyond its limits and borders.

You will say that the metaphysical body is given, consisting of genus and difference, just as every metaphysical composite is. Against this: according to

Pererius and Ruuius cited, the same thing is the physical body composed of matter and form and the metaphysical body, and the difference is only that it is abstracted from motion and sensible qualities — which distinguishes it from the physical body. But many things are composed from genus and difference which are not bodies, such as Angels. Therefore recourse to what is constituted from genus and difference does not avail to save the metaphysical body.

Assertion I: mobile being is not the proximate and adequate object of Physics. So Scotus (6. *Met. q. 1.*). This is proved: first, the adequate and proximate subject of a science is constituted in being through its proximate genus and proximate difference — otherwise its definition would be defective, as after Aristotle (6. *Top. loco 27. c. 1.*) the Doctor writes (1. *Poft. q. 24.*). But being is distant from mobile, and being is more broadly founded than mobile, since it is transcendent. Therefore mobile being is not the proximate and adequate object of Physics. Second: mobile is either a difference of being or a mode of it, since there is no middle between these. But mobile is not a difference of being — since being, according to Scotus, is not divided into differences; otherwise it would be a genus, which is commonly denied. But if it is conceded to be a mode, since the consideration of being and its modes pertains to that science, and Metaphysics contemplates being while Physics contemplates the mobile — it plainly follows that Physics is a part of Metaphysics, and consequently there are not three specifically distinct speculative sciences. Third: mobile is either a property of being, or its essence and intrinsic difference, or an extrinsic accidental difference. Not the first — otherwise Physics would be subalternated to Metaphysics, as Aegidius rightly argues against Aquinas. Not the second — as is proved by the second argument just given. If it is preferable to say that mobile is used for the root and internal principle of motion — as those recent thinkers cited, with whom the Complutenses subscribe (*disp. 1. q. 1.*), object against the Thomists — I oppose this: the root and intrinsic principle of motion is not mobile being, unless they mean that every being is mobile, which they themselves admit to be false. Not the third — because since a property flows from the essential principles of a subject and is convertible with that subject of which it is a property, given mobility as a property of being, every being would be mobile — which conflicts both with truth and with Aristotle. With truth indeed, since God is being and an immobile being; an Angel too is being and, according to Aristotle, an immobile being.

Assertion II: neither is the mobile body determined as the formal subject of Physics. Deduced from the Doctor (6. *Met. q. 1.*). This is proved: first, no science proves its subject a priori but presupposes it (1. *Poft. 1.*). But Physics (1. *Cæli T. 5.*) proves and demonstrates the mobile body by this syllogism: "What has an internal principle of motion is mobile; but the natural body has an internal principle of motion, which is nature (2. *phyf. T. 3.*); therefore the natural body is mobile." Second: no per accidens being is the object of any science, because (7. *Met. 12.*) a per accidens being is not definable. But the mobile body is a per

accidens being, for it is put together from body, which is substance, and from mobility, which is a proper accident or property of body, demonstrable of body (1. *Cæli* T. 5.). Therefore the mobile body is not the object of Physics.

You will say, with Javellus (4. *Met.*), that although mobility is an accident, it nonetheless functions in the role of a difference — as Aristotle argues elsewhere, cited by us, about the divisibility of quantity and the primary qualities of the elements. But this response helps nothing against our assertion. For in this manner it is not mobility itself but that notion, whose place mobility holds, that is the formal and essential difference of the object of Physics. Hence I argue thus: that is the formal objective notion of Physics which formally and essentially constitutes the object of Physics and distinguishes it from any other knowable object (*Log. loco cit. not. 1.*). But mobility is not of this sort, since it is a property of body, as Javellus cited does not deny. Therefore another formal objective notion, and another formal object of Physics, must be found — to be named and established in Article IV of this question.

One objects, first, against Assertion I: Aristotle (6. *Met. 1. & 11. eiusdem operis 3.*) writes that natural philosophy occupies itself with mobile being. He had previously stated this (1. 2. & 6. *Phyf.*), as well as (1. *Cæli 1.*). Nor does this seem incongruous: for just as first philosophy concerns itself with being as being, so second philosophy spends its attention on mobile being. Which the same Stagirite signified (6. *Met. T. 3.*), saying: "If there were no abstract substance, Physics would be first philosophy." Therefore, if between both doctrines there is a distinction on account of separated substances, it is not inaptly inferred that both consider being — and indeed Metaphysics being as such, and Physics mobile being. It is confirmed from (3. *phyf. T. 6.*): motion is defined as "the act of a being in potency" — not as "the act of the mobile body." And there, in the explanation of the already cited definition, an example is given from generation and corruption, whose subject is prime matter — which is indeed a being but not a body. Therefore mobile being is established as the total object of Physics. I respond: apart from the fact that, as Fuentes notes (*vbi supra, in fine art. 1.*), none of those cited authorities is expressly found in the translation of Perionius — granting and admitting those testimonies, Aristotle explains himself shortly afterward, for he adds that Physics speculates on natural substance (*Conimb. vbi supra in calce 1. art.*). And the same Stagirite had previously indicated (1. *Cæli 1. & 2. phyf. 12.*) and in other places — which, if rightly weighed, favor us more than the adversaries. To the other thing appended, I say that with the treatment of abstract substances removed from Metaphysics, Physics would be first in the priority of dignity — for after abstract and spiritual substances, the first place is held by corporeal and material substance, as is clear from the lists of all things adduced in the Logic (l. 2. & 3.). And therefore, given the hypothesis, Physics would shine before all other disciplines. This I proved on purpose in the preceding question (q. 2. 4.). Again, in the order of nature too, Physics would precede the other parts of philosophy — because, if transcendents and

abstractions from matter were removed, the corporeal and material substance would undoubtedly occur to us first, in the knowledge of which Physics is occupied. And so what Aristotle asserted would be true: with substances separated from matter removed, Physics would be the first philosophy — which the Coimbrans testify was the case among the older philosophers, who did not distinguish Physics from Metaphysics (*Conimb. cit. a. 3. ad 2.*). To the confirmation: it is clear from the second note that in the definition of motion, mobile being is taken for the composite from matter and form, which is the natural body. To the other matter, about generation and corruption, about which Aristotle adduces examples, I say that in these motion occurs per accidens. For in generation one proceeds from the imperfect to the perfect, and in corruption from the perfect to the imperfect. Although matter is in some way mobile, since it is a part of the natural and mobile body, it is reduced — as the quo by which motion occurs — to the natural body itself, which is the whole and the quod by which motion occurs.

One objects, second: what is the first and adequate subject of the first property of Physics is the first and adequate subject of natural philosophy. But mobile being is of this sort. Therefore mobile being is constituted as the total and adequate object of Physics. The major is evident and can be brought to bear on all the formal, proximate, and immediate objects of the sciences. The minor is shown. The first physical property is mobility — which is either subjective, or total substantial terminative, which is suited to the substantial composite, or partial substantial, which is accommodated to matter and form since they are natures — for nature (*2. phyf. T. 3.*) is the internal principle of motion and rest — and this is conspicuously seen in the rational soul, which is set in motion when separated from the body. Or total accidental, since the whole accidental is transmutable. For it comes to be from the privation of an accidental form; hence the Philosopher (*1. Phyf. 17.*) treats universally of the principles of natural things, comprehending both substantial and accidental generation — especially because accidents are per se mobile, as is evident from the accidents of the most holy Eucharist, which, separated from their subjects, are moved. Hence Aristotle, signifying all this (*3. phyf. 6. 9.*), sets down being as the adequate subject of motion, and then adds (*1. Cæli 1.*) that natural science speculates on bodies, magnitudes, and their affections. Again (*4. Met. 1.*): each of the particular sciences cuts off a part of being and meditates on it. From these and similar things amassed by Cajetan and others of his followers, mobile being seems to be concluded as the total object of Physics. I grant the major, I deny the minor. To its proof I say that matter and form are mobile as quo — the means by which — and are reduced to the natural body, which is mobile as quod — the whole by which — just as parts are reduced to the whole. Although the soul, or other part, can be separated from the body, nevertheless whether always conjoined with the body or separated from it, if it is mobile, it always exhibits an ordering, dependence, or inclination toward the body itself, and therefore will be reduced

to the whole, as complete and perfect. Accidents too are referred to the natural body as their adequate subject, to which they are ordered (*Scot. 4. d. 12. q. 2. §. Ad questionem.*). Therefore Aristotle could not rightly say that the adequate subject of Physics is the material substance prescinding from matter, form, and composite — nor the composite abstracting from the whole substantial and accidental — as our two recent thinkers cited freely grant to Aversa and the Cajetan cited by them. Because science is of one genus of subject (*1. Post. 33.*), which is a whole, not something prescinding from the whole and its parts. Indeed, besides Metaphysics, which looks to the transcendentals, the other sciences enjoy some generic subject — as is clear from the distribution of the objects of the speculative sciences given (*6. Met. c. 1.*). The reason is that the subject of any science contains potentially or virtually all the knowable truths demonstrable about it from (*2. q. prol.*) — which is undoubtedly a whole and perfect thing, not something imperfect, partial, and incomplete. Hence the Scotists, treating of the books *On the Soul*, set down as the total and adequate subject not the soul but the animated body — which is the perfect whole. Similarly in Logic, not the enunciation or the enthymeme but the syllogism, which is the whole, is determined by the same as the proximate subject of said Logic. As for the testimonies of the Philosopher appended by them — they have already been nearly all explained in the second note. For the aforesaid Philosopher very often accepts mobile being for the natural body and confounds the two (*Conimb. cit. ex. 1. Cæls 1. & 3. eiusdem operis T. 1. ac 10. Met. 1. nec non 11. eiusdem voluminis capite etiam 1.*), whom Averroes follows (*4. Met. com. 1. & l. 12. com. 5.*).

One objects, third, against Assertion II: Scotus (*q. 3. §. 35. vniuers. §. quantum ad 1. Et 1. post. q. 47. §. ad 1. argumentum*) expressly writes that the mobile body is the subject of Physics. Therefore in the Subtle school no other subject of Physics distant from the mobile body is to be sought. I respond with the Englishman, in his exposition of that passage, that Scotus speaks not in his own opinion but in that of others — as Aristotle is noted to do in the chapter on quantity by his commentators. Especially since the Doctor adduces this by way of example. In giving examples, moreover, one need not be overly scrupulous (*ex. 1. Prio.*). Veglia adds (*veft. 6. c. 9. 1. 1. anten. 40.*): in examples truth is not sought but only the manifestation of truth. Or it can be said that the Doctor is to be interpreted by taking "mobile" as a circumlocution for "natural body" — that is, taking the property for its subject, which Aristotle did (*5. Met. c. de quanto.*), defining quantity through divisibility, which is its first property. With this agrees what Scotus adds (*1. Met. q. 9.*), where, adducing Aristotle's saying that "Physics considers mobile things insofar as mobile," he notes that the Philosopher said this both because motion is better known, and also because it designates the convertibility and reciprocability of the property with its subject, as I was saying just now.

Article II. Whether the Generable and Corruptible Body Is the Total Object of Physics.

Some thinkers — such as Faber (*Faber Theor.* 20.), suppressing the name and rejecting it (*c.* 1. & *ibidem* *c.* 3.), and among them the twin Scotists at the beginning of the preliminary question refer and include Galen (*Galen.* 1. *de elementis simpl.*), Pererius (1. *Phyf.*), and Raguseius (*disp.* 1. *Perip.*) — judge the generable and corruptible body to be the object of Physics. Not far from these diverge those cited by Fuentes (*diff.* 1. *art.* 2. *num.* 4.) who suppose the object of the same science to be sensible substance — since every sensible sublunar thing is subject to generation and destruction, and thus the generable and corruptible seems to coincide per se or per accidens with the sensible. But the opposite is defended by Faber, Fuentes cited above, and the other philosophers who deny that either the generable and corruptible body or the sensible body is the object of natural philosophy.

Note that although it is at anyone's discretion to begin a treatment from this or that partial or total object, and to explore and examine this or that object — it is nevertheless not at the discretion of anyone to assign objects to sciences and to provide and constitute their formal and essential notion, as the undivided Scotists seem to wish (*cit.* 4. 1. & *apertè disp.* 12. *Log. q.* 3. *a.* 1.). For sciences are cut just as things are (3. *anima* T. 48.). From them sciences derive their unity (1. *post.* 32.) and are specified by them (*ibid.*): "One science is of one genus of subject." And from three formally speculable objects three specifically distinct speculative sciences are had (6. *Met.* 1.). The reason is that since sciences derive their entity from their formal objects, it plainly follows from those same objects that they derive their unity and distinction. Furthermore, formal objects — if they are generic, contain knowable truths potentially; if they are specific, virtually — as I maintained above. Again, demonstrations — whose effects are sciences — are discriminated according to diverse objects about which knowable properties are demonstrated. Then the knowable being depends on the being of the thing, and any knowledge is partially caused by the object of which it is knowledge. Nor does it escape me that some among the ancients and recent thinkers — notably Anthony Mirandola (13. *de everfione fingularis cert.*) — compose one science of all things and divide it into partial ones. But in order to remove confusion among things and introduce their distinction, Aristotle and nearly all later philosophers have especially brought in the discretion of sciences according to the distinction of formal objects. And those who before Aristotle did not distinguish the sciences according to the distinction of objects did not arrive at full and perfect knowledge of things, and appeared rather to babble than to philosophize aptly (1. *Met.* 6.). Finally, the end of a science is one thing, and the end of the knower is another, as I touched on at the end of the Logic (*adfinem lib.* 1.). The place of Scotus cited by our recent thinkers does not patronize them — both because it is an addition and is left under doubt, as those same authors confess, and also because everything I have noted is found in Scotus (*quest.* 3. *prol.*) and other

writings of the same Doctor. Nor in this and other matters that do not conflict with the faith did Scotus want to depart from Aristotle.

Assertion I: sensible substance is not the object of Physiology. Gathered from Scotus (*6. Met. q. 1.*). This is proved: first, the object of a science is one per se, just as the science itself is undoubtedly one per se, depending on the object from which it is generated and on the demonstration of which it is the effect (*1. post. T. 5.*). But sensible substance is not one per se — since sensibility is an accident, and from an accident and a subject what is made is one per accidens (*6. Met. T. 4.*) — both because (*7. Met. T. 12.*) it does not have a definition; and also because, as Bonetus notes (*1. Met. cap. 3.*), it is not a necessary being, since their union is contingent. Therefore sensible substance is not aptly determined as the object of Physics. Second: accidents are per se sensible (*2. animæ T. 65.*); substance, however, is called sensible per accidens and remotely. Here also belongs what I said in the preceding article about material substance taken precisely, insofar as it abstracts from matter, form, and composite, which cannot be placed as the formal object of this science — since incomplete and partial substance is reduced to the complete and total. And so, since sensible substance is said to be of those substances, it follows without hesitation that it is not the object of this discipline.

Assertion II: the generable and corruptible body is not the adequate object of Physics. Deduced from the Doctor in the cited passage and proved: first from Aristotle, who (*2. phys. T. 71.*) writes that those things that are moved while moving — whether corruptible or incorruptible, as heaven is — pertain to Physics. Again (*1. Cæli 1. & 1. Meteor. 1.*) he adds that all things constituted by nature and mobile are subject to the consideration of Physics. Furthermore (*5. Met. 7. 8. eiusdem operis*), among sensible substances and natural bodies he reckons heaven, which is perpetual and incorruptible. Second: every mobile body pertains to Physics, because mobility properly taken is a property of the mobile body — for body has a nature, which is the principle of motion and rest. Since, therefore, heaven has a nature (*1. Cæli s.*), it is clearly inferred that heaven itself pertains to Physics. The Philosopher indicating this, immediately after the eight books of Physics, adds the books on the heavens. Third: that science which treats of a genus undoubtedly discourses about its species, because the genus potentially contains its species. But Physics treats of the natural body taken generically, whose species are the celestial and sublunary bodies — as I noted in the preface to this work. I add that unless heaven fell under the object of Physics, the tripartite division of speculative science (*6. Met. 1.*) would be insufficient — for a fourth speculative science would have to be given that discourses about the celestial spheres, which opposes the torrent of the philosophers. Furthermore, the formal notion of the object of Physics cannot be corruptibility and generability, but is rather a property of the sublunary body. Hence Aristotle, treating of the subject of science in general, denies that it is a corruptible being. The reason is given by Bonetus (*1. Met. 3. §. Quinta.*): because

with the subject corrupted, the science of that subject is also corrupted, since the science consequently depends on that same subject.

One objects, first, against Assertion I: Aristotle (*12. Metaphysica sum. 1. capite 2.*) divides sensible substance into temporary and eternal, and holds that Physics is to be occupied in the contemplation of both. The reason can be that sensible substance moves our intellect to consideration of it. Therefore sensible substance must be set down as the object of Physics. I respond: the aforesaid division of substance is not that of a genus into species but of an accident into subjects. For sensibility belongs per se to accident and per accidens to material substance (*2. anima, 65.*). And so since sensibility cannot be the formal notion of sensible substance, the sensible substance itself cannot validly be the object of Physics. This is also confirmed by what I said in the preceding article in responding to the second objection.

One objects, second, against Assertion II: the object of Physics is to be determined whose principles and properties are treated in the eight books of Physics, because as what is common, they are suited to the rest of what is considered in Physics. But the principles and affections of the generable and corruptible body are handed down in the said work (*1. Phys. T. 56. & indè*), where matter, form, and privation are treated — which clearly do not belong to heaven, since it is incorruptible. All the more so since Aristotle thinks heaven is a simple body immune from matter, as Scotus notes (*2. d. 14. q. 1.*). I grant the major. To the minor I say that although principles and properties of this sort are assigned in the aforesaid work, it nevertheless does not follow that all of Physics is occupied with the generable and corruptible body, but with the natural body abstracting from the corruptible and the incorruptible — as the Philosopher clearly expounds (*2. Phys. T. 71.*), and as the same (*1. Cæli T. 5.*) indicates and the Coimbrans expound (*1. phys. capite f. quest. 1. a. 4.*).

You will insist: in the view of Aristotle, heaven is not composed from matter and form, as I touched on with Scotus above. Nor does it enjoy an internal principle of motion, since it is moved by an external thing — namely the intelligence. I say indeed that according to Aristotle heaven is a simple body; nevertheless, according to the theologians, heaven is compounded from matter and form, and is immediately incorruptible — not, however, remotely — because there is no other natural agent that can overcome its power and introduce another form distinct from that which it enjoys (*Scot. 2. dist. 14. quest. 1. 4. d. 49. quest. 6. §. Hic duo sunt Sub B.*). But heaven has an internal principle of motion, about which in its proper place.

One objects, third: the subject of a science must be univocal, since it is either generic or specific (*dictis supra*). But body, insofar as it comprehends both celestial and sublunary bodies, is not univocal. For (*10. Met. ad finem*), the corruptible and the incorruptible differ more than in genus. Since, therefore, heaven is incorruptible and sublunary things corruptible, it plainly follows that

Physics expends its effort solely on the sublunary body, which is generable and corruptible. I grant the major. I deny the minor. To the testimony of Aristotle I say it is to be interpreted of the physical genus, which is matter — not of the logical or metaphysical genus. Or you may say that the Philosopher himself is speaking of the proximate genus, not of the remote genus (*Scot. 4. d. 6. quest. 11. §. Ad quest. propè medium.*). This can be illustrated from stone and man, which, though they differ in the proximate genus, nevertheless agree in the remote genus — namely in the common notion of body and categorical substance.

Article III. Whether Finite Being Is the Object of Physics.

I see the Scotists divided three ways in this article. Some — such as Bonetus (*1. Phys. cap. 1. §. perscrutandum.*) and Tatarct (*ibid. quest. vn. scibili. 4.*), with whom Toledo seems at least verbally to agree (*eo loci quest. 2.*) — judge that the adequate subject of the whole of natural philosophy, considered in itself and in its full breadth, is finite natural being taken generally. Others — among whom are numbered Canonicus (*1. Phys. quest. 1.*) and Trombet (*6. Met. quest. 1.*), to whom the twin Scotists adhere (*quest. proæm. a. 2.*) — establish as the total subject of Physics considered in itself the finite natural substance. The rest — notably Faber (*Faber Theor. 20. cap. 1.*), Fuentes (*quest. 1. proæm. a. 2.*) — deny that either finite natural being or finite natural substance is the adequate and proximate subject of Physics — whether considered in itself or in any other manner.

The tripartite distribution of speculative sciences acquired through the service of the senses, handed down (*6. Met. 1.*) and explained by me (*Log. lib. 5. quest. 4. a. 6.*), is to be recalled. Furthermore: just as one speculative science of corporeal substance is admitted, so another speculative science of incorporeal substance is to be conceded. But because the proper predicates and properties of incorporeal substance are not knowable and demonstrable by us through sense, and because what we know about such substance consists of common and transcendent predicates, therefore we do not have of that same substance another science distinct from Metaphysics. For Metaphysics, as the universal and common doctrine, contemplates the common and universal predicates of each substance and of whatever else there is. Note also that both nature and what has a nature are substance (*2. Phys. T. 4.*) — not indeed incorporeal substance, which Physics does not care about, but corporeal and material substance, which Physics itself meditates (*1. Cæli 1. & 1. de partibus animalium 1.*) — as Veglia accumulates from many places (*vest. 6. cap. 1. & indè*). Furthermore, the same thing, under diverse formal aspects, is treated by diverse sciences — after Aristotle (*2. Phys. 18.*): as Orbellis notes (*cit. in fine*), Physics considers quantity as an affection of the natural body; Mathematics considers it precisely insofar as it is quantity; and Metaphysics considers it as being.

Assertion I: finite and limited being is not the object of Physics. Drawn from Scotus (*6. Met. quest. 1.*) and consonant with Aristotle in the places just cited. This is proved: first, Physics does not concern itself with the inspection of finite being

— since that is the office of Metaphysics, as is clear (*5. Met. T. 14.*), where Aristotle divides finite being into the ten categories, which also, according to Bonetus cited, are not considered by Physics as its object. If, therefore, Metaphysics examines the ten predicaments, into which as into ten modes finite being is distributed, then finite being too is surveyed by Metaphysics itself — since it belongs to the same science to investigate the dividing members and the divided. Hence the same Bonetus confesses (*9. Met. cap. 2.*) that he has brought the partition of being into infinite and finite. Second: from the distinction of objects the division of sciences is derived — a common axiom received and defended by the same Bonetus there. But the finite and the infinite are modes of being, as I will show in the Metaphysics. Therefore finite being is not determined as the object of Physics — otherwise there would be only two sciences posited, one of the infinite and another of the finite, whereas the same Bonetus admits Metaphysics as a science distinct from the rest, whose concern he wants to be to speculate on being, which he calls the first nature of origin, and on the first intelligence, which he names the first nature of perfection, which is the infinite God. For if from the second nature one science is constituted, without doubt from the first nature another science is to be established. Furthermore, finite being comprehends accident, which Orbellis particularly notes (*præcit.*) is the object of no science. Here also belong the things I adduced in Article I of this question to repel mobile being from the object of Physics.

Assertion II: finite natural substance is not the proximate and adequate object of Physics. This follows from the sayings of the Doctor cited and is urged: first, the subject of science is presupposed as to whether it exists and what it is, and about its knowable properties are demonstrated (*1. post. 1.*). But in Physics, finite natural substance is not presupposed as to whether it exists and what it is. For finite natural substance is nowhere in Physics defined, nor are its affections demonstrated, as is evident to anyone going through all the books of Physics. Therefore finite natural substance is not established as the object of Physics.

You will say: this argument proves only with regard to the object of Physics as delivered by Aristotle, not with regard to its object taken in its full amplitude, as the aforesaid Scotists speak. But this response does not seem to be of any weight. For, besides the fact that the said authors make Aristotle defective and diminished in establishing the object of Physics, the subject of any science — since it precedes the science and its author — is not constituted at the discretion and pleasure of the same author, as I considered and confirmed in the preceding article. Especially because the respect of the author of a science is entirely extrinsic, both to the science itself and to its object. Above all, almost all philosophers acknowledge that Aristotle delivered Physics complete and perfect in all its numbers, as is clear from the enumeration of its parts briefly assigned in the beginning of this work. To devise another broader Physics and a broader object for it is something for which neither any authority nor any argument of

any moment is adduced to support it, as will be evident from the resolution of the objections to be adduced below. Although in the Logic I use this distinction in establishing the object of Logic, yet there a sufficient foundation is laid and a sufficiently firm reason given for not disapproving that distinction. Second: the well-established distinction received by all between Physics and Metaphysics, drawn from the Philosopher passim in his writings — notably (*2. Phys.* 18. & 6. *Met.* 2. & 1. *de partib. animalium*, 1.), whose words are these: "No natural science can contemplate a thing abstracted from matter, since nature makes all things for some purpose; but what we understand by the phrase 'for one thing's sake' is divorced from abstract things." Then (*12. Met. cap. 2.*) the same Philosopher treats of finite and infinite substance, as the Doctor notes (*ad finem quol.* 7.). Therefore finite natural substance is not decreed the object of Physics — otherwise Physics would not differ from Metaphysics. Furthermore, Aristotle (*6. Met.*) in the cited passage derives the distinction of speculative sciences — among which Physics is mentioned — not from the finiteness or infiniteness of substance, as may be observed there and as I expressed in the cited Logic. Third: given that opinion, Angels would fall under the object of Physics, since they are finite substances — and those authors concede this. But they are not comprehended under the object of Physics, nor does Physics itself demonstrate their proper properties — since they are not subject to the senses, being devoid of matter and form. Rather, another science would have to be assigned for them than to include them under Physics. I add that their location is definitive, distinct from the circumscriptive (*Veglia velt.* 6. 1. 2. c. 5. num. 93.), and (*1. Cæli T.* 100.) they are said not to be in place. Likewise their motion is of another nature, as Tataret asks dubiously and other scholastics assert. Therefore they are not subject to the consideration of Physics.

You will say, with Trombet and the undivided Scotists (*cit. q. 2.*): the motion of Angels, though subjectively spiritual, is nevertheless, by reason of the space and things through which it is effected, extended and material — and therefore in this respect it pertains to Physics. But this response removes the substance of the Angel, which is finite, from the object of Physics while including its motion under the same object — and so finite substance is wrongly established as the object of this science, but rather mobile being, which the said authors reject together with us. And if the motion of an Angel is contained under this object on account of material and extended space, equally the intellection of the same Angel about a quantified and material object objectively and terminatively pertains to Physics — since in both cases the reason is equal. Again, if motion were to occur in an instant — which the Doctor (*2. d. 2. q. 11.*) does not deny to be possible — and likewise if God were to destroy that positive and material space, there would certainly be nothing by reason of which the motion would be called material and extended. Finally, even the motion by which God moves material and corporeal things would be regarded by Physics. And thus not only

finite but even infinite substance would be the subject of Physics — which none of the objectors dares say, and which all see to be plainly false.

One objects, first, against Assertion I: the distinction of sciences is derived from the distinction of objects (*1. post. T. 43.*). But the object of Metaphysics is being (*4. Met. 1.*). Therefore the object of Physics — which immediately follows it — is finite being. It is confirmed: not only finite substance is mobile, but accident too is mobile, as is clear in the Eucharist. Therefore the adequate object of Physics comprehends both finite substance and accident, which is finite being. I respond: it is not from the finiteness or infiniteness of being — which are modes of it pertaining to Metaphysics — that Physics and the other sciences derive their specificative and distinctive objects, but from substance in terms of its formal notions. But accident is the subject of no science (*Orbel. præcit. ex 6. Met. T. 5.*) — because it cannot be the first and ultimate subject of demonstrable properties, since it is ordered toward substance, from which it is produced and on which it depends for its being. Hence it is called its being (*1. Eth. cap. 6.*). Wherefore, to the confirmation I say that accident is mobile not of itself but dependently on substance; and since it is referred to the substance in which it is subjected, it is therefore contained under substance — and so what is more common and broader than corporeal substance and the natural body is not to be assigned as the object of Physics.

One objects, second: that in which mobility — which is the first property of natural substance — is adequately subjected is to be decreed the total object of Physics in its full breadth. But finite substance — which comprehends both incorporeal substance, such as the Angel who is mobile, and corporeal substance as the total physical being — is the first and adequate subject of mobility. Therefore the total and adequate object of Physics is finite substance. It is confirmed: Aristotle separates from Physics the abstract substances because he judges them to be immobile and immutable (*1. Cæli T. 100. Et 12. Met. T. 5.*). If, therefore, he knew them to be mobile — as the Doctor truly shows they are (*2. d. 2. quest. 9.*) — he would undoubtedly include them in the object of Physics. I respond by distinguishing the major: regarding sensible and material mobility, which proceeds from the physical composite and is most of all subjected in it — granted; regarding insensible and spiritual mobility, not indeed from the side of the space to be traversed but from the side of the mobile — denied. To the distinction of the major I distinguish the minor: for, as the Stagirite clearly delivers (*12. Met. cap. 2. ad T. 6.*), sensible substance and its motion pertain to natural philosophy; but insensible substance separable from matter pertains to Metaphysics. For the mobility of the latter is of another nature from the mobility of the former (*Tatar. cit. cum Doct. 2. d. 2. quest. 6. §. Ad propositum. O.*).

You will insist: the rational soul is altered in the body and is moved in it, and receives such motion — which also pertains to Physics. Therefore the same is to be asserted about the motion of the Angel. I add: Scotus (*cit. quest. 11. §. dico sub.*

O.) argues that the notion of place is a common univocal notion for both the circumscriptive place, which is suited to the natural body, and the definitive place, which is suited to the Angel. Equally, there is no inconvenience in having the universal notion of mobility convene univocally with the mobility of each — in roughly the same way as the human intellect and the angelic intellect participate in the common notion of an intellective principle, and as the vision of an ox and an eagle are of the same species (*Scot. cit. d. 1. quest. 6. §. potest etiam. D.*). Therefore the aforesaid distinction about mobility dissolves the argument, even though their natures differ in species. The parity is to be denied. For the soul is the informing, constitutive, and perfecting part of the body — and it belongs to the same science to speculate on the whole in which it is occupied and on its parts, principles, and properties. Wherefore, since Physics contemplates the animated body, it likewise contemplates its parts, among which the soul shines preeminently. Likewise it meditates on the faculties and affections of the soul itself, in the number of which mobility is found. But since the Angel is separated from matter and has nothing material, consequently neither its essence nor its principles and properties — among which mobility exists — are subject to the consideration of Physics, as the Doctor just cited intimates (§. *conclusis.*).

To the other thing appended, I say: even if the definition of place delivered (*4. phys. T. 41.*) is suited only to the circumscriptive place — which Gilbert of Poitiers (*1. Sex principip.*) and others also accept — and even if it is admitted that material and immaterial substance participate in the common notion of place prescinding from circumscriptive and definitive place, it is not inferred from this that each place is of the same nature — just as man and Angel have the common concept of transcendental and predicamental substance, yet all confess them to differ in species. Similarly substance and accident are univocal in the common concept of being, according to Scotus, yet no one doubts they are of another nature. And so, given that the abstract and matter-conjoined substance enjoys a common and general notion of mobility, it is not well deduced that the mobility of each is of the same nature — since they proceed from diverse principles and subjects, whose powers and properties are diverse. Nor does the opinion of the adversaries have support from the Doctor. For even if he should want the intellect of the Angel and of man to participate in the same notion, perhaps he asserts this because each intellect is spiritual and enjoys a spiritual principle of understanding and labors about the same object. Similarly the Doctor adds (*ibid.*) that the vision of an ox and an eagle does not differ in species because both are material, engaged about the same object. Yet since the mobility of the Angel is formally and subjectively spiritual, and the mobility of the natural body is material, it does not seem to be of the same species — except very remotely — nor to be examined by one and the same science. To the confirmation: let us grant that Aristotle judges those substances to be necessary, immobile, even uncaused — which the Doctor shows does not savor of truth (*1.*

d. 8. q. 5. Et quol. pracic.) — and I demonstrate at length (*Tract. de creatione disp. 1. q. 17.*): for God alone is immobile, immutable, and uncaused (*8. Phys. T. 34. 37. inde, necnon 12. Met. T. 38. 41. 49.*). Nevertheless, the precise reason why those substances are considered by Metaphysics is not their immobility but because they are devoid of matter and separated from it, as the Philosopher lucidly expounds (*2. Phys. T. 26. Et 1. Phys. T. 83. 6. Met. T. 3.*): if there were no abstract substances, Physics would be first philosophy — since, given the hypothesis, there would be only material substances, which are treated by Physics.

Article IV. Whether the Natural Body Is the Object of Physics.

A few thinkers, whom Aversa follows and cites (*2. 3.*), hold that the natural body as natural is the formal and proximate subject of Physics. But the common opinion at this time is strenuously defended by Faber (*Theor. 20.*), Fuentes (*in proæm. Phys. a. 3.*), Hurtado, Arriaga, and others — preceded by Scotus (*6. Met. q. 1.*), Anthony Andrew, and others in that place — who affirm that the natural body as natural is the adequate and formal object of attribution of natural philosophy.

Note that "natural" is derived from nature, which is taken in many ways (*q. 1. prot. L. Et 2. d. 18. q. vn. B.*) — and "natural" has many acceptations (*4. d. 43. q. 4. §. Intelligendum A.*), which are touched on (*Dyol. 17. prope initium*) and adduced by me (*l. 3. de natura, & arte q. 1. a. 1.*). Furthermore, I note that "natural," or the natural thing, is the total physical being — named the composite from matter and form (*2. Phys. 1. Cæli t.*). Then the Philosopher (*2. Phys.*) divides nature into matter and form, and makes privation in some way a nature; but the being that consists in nature is the substantial composite, which has matter and form — each of which is nature. Hence the same Aristotle (*1. Phys. in proæ.*) had previously noted that he must treat of the principles of natural science, which are matter, form, and privation; and there (*a 2.*) he calls questions about these natural questions. And at the end of that book he remits discourse on separate forms to first philosophy, because that is not natural. The same is delivered (*1. 2. Phys. c. 2.*). Furthermore, Aristotle inscribes the first work of the Metaphysics as being after physical things. Wherefore nature properly, and the natural, in the second philosophy, by no means spreads and extends to substances separated from matter and to insensible and immaterial beings. And those who discourse otherwise about these speak unnaturally, as Cajetan objects in the present question. Furthermore, recall from what was said in the Logic (*q. 3. a. 1. 1. 1.*) that the scientific subject which is too broad, regarded by several sciences, is restricted and limited through the formal and intrinsic notion by which it is determined and appropriated to only one science. Thus the natural body — which is the material object of Physics, about which Medicine also concerns itself — through healability, which is the formal notion of the healable natural body, is determined, made adequate, and regarded by Medicine alone. Similarly, through naturalness, the natural body is contracted, restricted, and

considered only by Physiology. Wherefore to derive the unity and specification of a science from its formal object is a common maxim among philosophers.

Assertion: the natural body as natural is established as the formal and adequate object of the whole of Physics. That this is according to the mind of the Doctor (6. *Met. q. 1.*) is maintained by the Parisians (*in fine q. alleg.*). This is proved: first from Aristotle (2. *Phyf. & 1. Cæli præcit.*), saying that Physics is concerned with what consists in nature. But what consists in nature is the natural body, as I was explaining just above. Then (6. *Met. 1.*): natural science speculates on corporeal substance in which there is a principle of motion and rest. The same is read (11. *Met. 1. 12. eiusdem operis T. 6.*). Second: the natural body has all the conditions required for the formal and proximate object of Physics. Therefore it is to be determined as its total and adequate object. The antecedent is urged from what was said in the Logic in the place just mentioned: there are three necessary conditions for the formal subject of a science. First, that the subject be presupposed as to whether it exists and what it is. Second, that it have knowable properties demonstrable from its principles. Third, that to it all things treated in the science are reduced. But these three conditions are suited to the natural body. The first indeed: for since Aristotle (2. *Phyf. 1.*) delivers the definition of the natural body, it is thus presupposed about the natural body itself whether it exists — for the question of what a thing is is never raised unless it is presupposed whether it exists. Second, because both its incomplex principles are delivered — which are matter, form, and privation (1. *phyf. T. 56.*) — and complex ones — which are its axioms, such as "nature does what is best" — and knowable properties are demonstrated of it, such as mobility (1. *Cæli, 1.*). Third and finally: because all things are comprehended under the natural body — either as parts, or as properties, or as species, or per se, or per accidens — as is evident to anyone reading the books of Physics. Third: what is the root and originating principle of all the affections and properties of Physics is by unanimous and unhesitating consent judged to be the formal and total object of Physics. But the natural body is of this sort: from it flow quantity, quality, place, time, motion, and other things of this kind. Fourth: from the refutation of the others. Since, from what was proved above (*art. 1. huius q.*), it is not mobile being, nor the mobile body, nor the generable and corruptible body (*ibid. a. 2.*), nor finite being and finite substance (*co loci, a. 3.*) — consequently and sufficiently it is concluded that it is the natural body as natural.

One objects, first: the object is not proved but presupposed by the science of which it is the object (1. *post. c. 1.*). But the natural body is proved (2. *Phyf. 31.*). Therefore the natural body is not the subject of Physics. I grant the major, I deny the minor. For there it is only shown that every mobile thing is quantified and divisible — but it is clear that the quantified and divisible does not coincide with the natural body. This the Philosopher plainly indicates (2. *Phyf. T. 6.*), saying that the existence of nature is not argued for but presupposed. And (1. *Phyf. T. 11.*): "That some things are moved is manifest."

One objects, second: the formal object is what is proper and distinctive of one science from another, for from it the science derives its unity and distinction (3. *anima*, 38.). But "natural" is common to other sciences — for Metaphysics (5. *diuinarum* T. 5. c. 4.) defines nature as the principle of motion and rest; it likewise contemplates the four genera of causes (*ibid.* T. 2.). Again, Astrology considers the natural body, its motion, figure, and position (10. *Met.* 4.). Furthermore, Medicine examines the natural body itself along with its powers and natural affections. Therefore the natural body is not the first and adequate object of Physics. I grant the major, I deny the minor. To its proof I say that Metaphysics inspects nature, causes, and things of this kind not in terms of their proper predicates, under the notion of naturalness, but in terms of common and transcendent attributes — since it is a common and general science investigating the common and transcendental notions of all things. Hence it is clear what is to be said of Astrology, which surveys celestial bodies under the mathematical notion, inquiring their measure, order, position, equality, and other things of this form — and not under the notion of naturalness, as Physics does. About Medicine it is clear that it has its own formal and objective notion, which is healability — distinct from the formal and objective notion of Physics, which is naturalness.

One objects, third: the formal object is the principle and proximate foundation, and the origin of all the properties and accidents treated in the science of which it is said to be the formal object. But "natural" comprehends only those things that come about through motion, not through mutation and simple emanation — such as those which are congenital and always conjoined with those of which they are properties, as quantity with corporeal substance, powers with the soul, and the like. Therefore naturalness is not the proximate and adequate notion of the formal object of Physics. I grant the major, I deny the minor. For under those words "of motion and rest" placed in the definition of nature are contained all the properties of Physics — whether they be congenital with their subjects or not; whether they proceed from the natural body through motion or through mutation and simple emanation. This will become clearer in its proper place, in the explanation of the said definition of nature, and will be confirmed through the definition of the efficient cause — which is such a principle whence motion and rest.

You ask: what is the object of the eight physical books? Scotus responds (*q. 3. vniuers. ad 2.*) that it is the natural body taken precisely, insofar as it abstracts from its species — concerning which Mastrius and Bellutus are to be seen (*quest. proæm.*).

Book II. On the Principles of Natural Things.

Aristotle is no sluggish executor of the precept he himself laid down at the very beginning — (*1. Phys. 1.*) — that in every discipline one must begin from its principles, causes, and elements; and a few passages later (*T. 4.*) — that one must advance from what is more common and universal to what is less common. For when these are first known and understood, anyone may easily attain knowledge and understanding of the other things of which they are the principles and causes. Once the causes are known, it is no difficult or troublesome matter to know their effects. I follow this method, which I likewise observed and set forth in the Logic — most particularly in its preface and at the beginning of Book I. Accordingly, I judge that one should treat first of the principles of natural things in general; thereafter of the same in particular; and finally of the remaining matters that follow from them.

Question I. On Principles Taken in General.

No philosopher, whether ancient or modern, calls into doubt whether natural principles exist. For this is held to be manifest in the transmutation of natural composites, which presuppose principles and parts from which they are generated and composed; and likewise in the natural agent, which presupposes a subject upon which it acts, into which it introduces — or rather educes — something from the subject, of which that same subject was previously deprived. But what, how many, and what kind natural principles are — the many discordant opinions and conflicting views of the Ancients are recounted at length and admirably refuted by Aristotle (*1. Phys. cc. 3 and following*). I shall set forth clearly what I judge opportune and necessary concerning these principles through the articles that follow, and I shall resolve the questions as best I can.

Article I. What Natural Principles Are.

Since the philosophers recalled in the preceding remarks have reasoned about principles in such varied ways that some of them spoke about these matters in an unnatural fashion — a fault for which Aristotle reproaches them (*ibid. c. 3*) — while others spoke in so stammering and discordant a fashion about the same matters that one may rightly say of them what is said of those who disagree: "as many heads, so many opinions" — it pleases me to investigate carefully and precisely what is said about the aforementioned principles both in general and in particular. And so that their nature may be more clearly evident to us, and their distinction from one another and from other things more easily understood:

First Note, from Scotus (*4. Met. in tex. p. 96.*), Averroes (*5. Met. in com. c. 1.*), Vorrlong (*1. d. 29.*), and Fonseca (*l. 5. Met. in expositione c. 1.*), these three — principle, cause, and element — stand to one another as superior and inferior, so that principle is the highest, cause is inferior to it, and element is the lowest

of all. For every cause is a principle, but not every principle is a cause — just as place is indeed a principle from which motion proceeds, but not its cause. Similarly, every element is a cause, but not every cause is an element — as is evident from the final and efficient cause, which is not an element, since an element belongs intrinsically to what is elementated, just as letters, which are the elements of speech, belong to its composition and integrity. This may in some measure be illustrated and clarified by these three terms: produced, created, and caused — among which produced has a wider extension than created, and caused wider than the latter, as Mayr observes (*1. d. 8. q. 7.*). For in the divine persons, the Son is produced but not created, nor caused — as the Athanasian Creed affirms: "not made, nor created." The same point may be noted with these three verbs: to emanate, to be produced, and to be generated. For the divine attributes emanate and spring forth from God's essence, but they are neither produced nor generated; and the Holy Spirit is produced by the Father and the Son, but is not generated by them. More on this in the Treatise on God as One (*disp. 3*) and the Treatise on God as Triune (*disp. 1*).

The reason why not every principle is a cause can be given as follows: something can be the principle of another thing even if it exerts no influence upon it — as is evident from privation, which is numbered among the principles, even though it exerts no influence upon the composite. A cause, however, in the usage of the Latin scholastics, always concurs in the production of its effect and exerts influence upon the very effect itself, which is distinct from the cause in species or in number — as will be shown when causes in general are treated.

I am not unaware that the Philosopher sometimes conflates principle with cause and uses both terms interchangeably. For at (*12. Met. T. 12. c. 2.*) he explicitly calls privation a cause. And at (*5. ibid.*), after listing various senses of principle, he finally concludes: "Causes are said in as many ways as principles." And at (*4. Met. c. 2. T. 3.*) he had premised that cause and principle are interchangeable, just as being and one — it therefore follows, on Aristotle's account, that cause has the same extension as principle. However, Suárez (*disp. 12. Met. Sect. 1. n. 26 and following*), Fonseca (*cit. q. 7. sect. 2.*), and Pereira (*1. 3. de principiis c. 1.*) adduce and reject many responses given by great scholars to the aforementioned passages of the Philosopher, and in the end they concede — Suárez explicitly at (*cit. n. 30.*) — that principle taken in whatever sense is more common and universal than cause. And so those testimonies of the Philosopher stand in their force, and they appear to amount to a modest concession of Aristotle's lapse — as the aforementioned Suárez charges others: for if principle taken in any sense whatever has a wider extension than cause, then Aristotle was wrong to say that principle is interchangeable with cause as one is interchangeable with being, and that causes are said in as many ways as principles, and that privation is a cause.

Furthermore, the Greek Fathers — Chrysostom, Theodoret in their commentaries on the Epistle to the Hebrews, Damascene (*1. fidei, 11.*), and others

cited by the Conimbricenses (*1. Phys. c. 5. q. 1. a. 1.*) — hold the same view. And in the acts of the Council of Nicaea, St. Athanasius used cause in place of principle. Why may Aristotle not do the same, given that he too was Greek and used the same acceptance? All the more so since certain Latin writers — among them Augustine (*7. Trin. 1.*) and (*l. 83. qq. q. 16.*), and Jerome in his commentary on (*c. 3 of the Epistle to the Ephesians*) — used cause in the sense of principle. I add that those same authors do not reject the common, popular acceptance of cause as any kind of principle, even one that exerts no influence upon an effect — as Fonseca senses (*4. Met. T. 3.*) and Suárez concedes (*n. 29.*) from (*12. Met. T. 12.*). Yet Suárez himself is reluctant to grant this, lest he be forced to assert that cause and principle are equally common in extension.

To remove every difficulty and settle the dispute in the matter itself and in Aristotle, it seems to me that one must say that principle can be taken in two ways — commonly and properly. Taken commonly, principle and cause in a broad sense coincide; and in this sense Aristotle is to be understood when he says (*5. Met. T. cit.*) that causes are said in as many ways as principles, and (*4. Met. at the passage cited*) that cause is interchangeable with principle as one is with being, and (*12. ibid.*) that privation is a cause. In the same sense Jerome is expounded: "The Father is the origin and in some manner the cause of the substance" of the Son. And Augustine (*4. Trin. c. 20.*): "The Father is the principle of the whole divinity." Properly, however, principle is that which exerts influence upon what is produced and is called the origin of one thing from another — thus in the divine persons the Father is the principle of the Son, and the Father and Son are the principle of the Holy Spirit. Principle so taken and cause, among the Greeks, are interchangeable — as is clear from the Fathers cited above, and as is received in the Council of Florence (*sess. ult. in the letters of holy union*). Among the Latins, however, they are by no means interchangeable, since the Latins take cause more strictly, as what provides being to the effect that depends upon it and exists in a species or number distinct from it. In this way cause and principle are not interchangeable, since principle is wider than cause.

For this reason Aristotle, treating of cause as distinct from principle, perhaps discusses it later (*6. 2. 1. 5. Met.*) in roughly the same manner as he had reasoned at (*2. Phys. sum. 3. c. 1.*), as Orbellus and Tartaretus note there. Moreover, in created things, principle and that which is principiated enjoy distinct natures, just as cause and effect do, and one always depends upon the other; nor should one suppose that Aristotle acknowledged one thing to be produced from another without dependence, or that the principiated is not the correlative of the principle in divine matters — as the Latins hold, on which see the Treatise on the Trinity (*disp. 2. q. 6.*) at length.

Furthermore, this twofold acceptance of principle and cause does not seem incongruous. It is akin to the use of being and thing, which the Doctor sets forth (*Quol. 2. § De 1.*) and which Orbellus explains (*4. Met. quaest. 1. 2.*), and which

Aristotle indicates at the passage just cited, subjoining the common definition of principle, to be adduced in the next note.

Second Note: from various writings and different passages of Aristotle, four descriptions of principle are to be derived — three in the singular and the fourth in the plural. The first is found near the beginning of the *Poetics*: "A beginning is that which does not itself necessarily follow upon something else, while something else naturally is or comes to be after it." This account of principle is restricted by Fonseca (*cit. q. 1. Sect. Prima*) to the principle of a quantitative and extended thing only — such as the unit of number, the point of a line, and the instant of time. But it is, as Suárez writes following Damascene in his *Dialogue against the Manichaeans* (*cit. n. 4.*), most broad and highly equivocal. For it can extend not only to quantities but also to qualities — so that the first degree of a quality is called its principle, a foundation is the principle of a house, a higher place is the principle of a lower one, letters are the principle of grammar, the exordium of a speech, and the terms of dialectic. This Fonseca seems also to sense, extending that definition of principle to things that are actually or potentially principles, as well as to those very things from which others are or come to be.

The second is given (*5. de generatione animalium c. 7.*): "That is a principle, that is itself the cause of many things, but has no superior cause above it." This account of principle appears broader than the preceding. For since principle is defined through cause — as if cause were the genus and something superior to it — cause appears to be superior and more extensive than principle. But although in a broad signification cause and principle possess the same extension, as has been said, nonetheless, since cause regards a caused thing and effect that depend upon it essentially, and principle taken properly, though it always exerts influence upon what is produced or communicates being to it, yet what is produced does not always depend upon the producer — as is evident from the divine Persons who are produced, among whom there is indeed co-requiredness but not dependence, and priority of origin but not priority of nature or time — it follows that cause properly is not more extensive than principle; on the contrary, it is narrower, since it concerns only those things that enjoy essential dependence upon one another, such as the many effects proceeding from one cause, of which it is called the first cause and the principle in that series and order — much as the ten predicaments are said to be the ten first genera.

The third is drawn at (*5. Met. 1.*): "A principle is the first from which something actually is, or comes to be, or is known." There Aristotle and his interpreters note that "first" applies to all principles — for every principle is first, yet not every first thing is a principle, since being is the first of all things of which it is predicated, yet one cannot call it a principle of God, since God is without a principle, indeed is himself the principle and end of all things (*Apoc. 1.*). Thus a principle is said to

be first absolutely, and something is called a principle in a given order when in that very order it is preceded by no other. In this way, in the order of the divine Persons, the Father is the principle of the entire divinity — as Augustine writes (*4. Trin. c. 20.*): "Among universals, genus; among predicaments, substance; among natural principles, matter; among men, Adam; and among the Friars Minor, St. Francis." Similarly, something is called a first principle in a qualified sense within a given order — thus an intermediate point is called the first and principle of the subsequent points of a line, and an intermediate instant of time is called a principle comparatively, that is, in relation to the other instants succeeding it in time.

Hence it is essential to a principle to be first and to be prior to that which is from it — whether absolutely or relatively, and in whatever order. In created things, a cause is at least prior by nature to its effect; and in the divine persons, the Father is prior in origin to the Son — on which see the Treatise on God as Triune at length.

In the aforementioned definition, the word "from which" is placed to designate the consequence or connection between a principle and something else that is from it. Since a principle is a relative thing — as Vorrlong concedes (*cit.*) — it must regard another, which in some manner is from it: either consecutively, as the first instant regards the second instant; or originatively, as a father regards his son; or causatively, as a cause regards its effect. This Aristotle expressed by adding: "from which something is, or comes to be, or is known" — wherein three kinds of principles are signified. Some, from which other things are, though they produce and exert no influence whatsoever upon those of which they are principles — as a point is called the principle of a line, and privation of natural generation. Others communicate being to what is produced, yet do not properly cause it — as has been said above of the divine Persons who produce, with respect to the Persons who are produced. And still others properly cause what is produced — as in created things a father causes his son. The remaining ones are principles of knowing, called dignities, suppositions, and axioms of the disciplines — of which Aristotle makes mention (*1. Post. cc. 9–10.*).

One might object: a true definition is given through genus and difference, as asserted in the Epitome (*1. 2. q. 7. art. 2.*); but that definition of principle is given through members into which it is divided, which appear to be rather its species than its genus and difference. It is also assigned by way of disjunction, and therefore is not a suitable definition. I grant the major and concede this much to the minor: I say that this is sometimes done when the proper genus and difference of the thing defined are not fully known to us, as Aristotle himself does (*1. Prior. 1.*) in defining the proposition through the affirmative and the negative, which are evidently its species — as I noted in the Epitome (*cit. q. 2. a. 2.*). In like manner it can be said in the present case that Aristotle assigned and set forth the aforementioned definition of principle through its dividing

members or quasi-species — especially because for things that are so broad, diffuse, equivocal, and transcendent, one can scarcely give a strict definition, but only a certain description and notification.

A most general definition of principle, suitable to all principles, can however be given in these words: "A principle is the first from which something follows." Here "first" serves as a kind of genus, and the remaining words serve as a kind of difference. Principle taken in this way is distributed into three members signified by the words of the Aristotelian definition: "from which something is, or comes to be, or is known."

The fourth definition is read (*1. Phys. c. 1. T. 42.*): "Principles are those things that are made neither from others, nor from one another mutually, but all things are made from them." This definition is proper and adapted exclusively to the principles of natural things, all interpreters agreeing there — except Arriaga (*disp. 1. sect. 2. n. 4.*) and Hurtado (*ibid.*), who make it common to every principle, even outside of Physics — including God, as the principle of created things, and Adam, as the principle of human beings. But apart from the fact that this definition is taken collectively, not distributively — as Fonseca rightly notes (*cit. q. 2. sect. 2.*) — for it is not principle in the singular but principles in the plural that are described, and those who, like Melissus and Parmenides, decreed one immovable principle such as God, are censured by Aristotle as speaking in an unnatural fashion (*cit. c. 2. qq. 7–8.*) — he himself treats of the first and immovable principle (*12. Met. sum. 2. c. 2. and following*), which is called the first principle and immovable, from which all things are moved, depend, and are essentially subordinated. Aristotle also investigates the principles of natural generation and composition, as is evident at the passage just cited, and his conclusion (*ibid. c. 7. T. 68.*) is stated in these words: "I have now sufficiently explained how many principles of natural things there are, those to which generation belongs, and in what manner they are so many." Furthermore, (*5. Met. 2.*) the efficient cause is described as the first principle from which motion and rest proceed — or from which motion and rest originate. From all this it is sufficiently indicated that God, who is the efficient cause of creatures, is their extrinsic principle. Since, then, Aristotle in the Physics discusses the intrinsic principles of natural things, it is clearly established that the aforementioned definition does not apply to God as the effective principle of things. Again, the preposition "from" placed in that definition does not designate the relation of an efficient cause to its effect. For although it is sometimes so taken — as Hurtado endeavors to urge from Sacred Scripture — yet it is not properly used by philosophers to denote the order to extrinsic causes; for a thing is not properly said to be made "from" an agent, but "by" an agent, as is explicitly stated (*1. Phys. c. 4. T. 40.*), and (*5. Met. T. 2.*), and as will be made clearer in the book on causes. Hence David of Dinant, who supposed God to be prime matter from which all things were created, is commonly censured.

Moreover, all philosophers together with Aristotle, from the foregoing remarks, concede that principles are contraries and that all natural composites come to be from them — either as from a terminus a quo or as from component parts. Furthermore, the three necessary conditions for those principles, set forth in the aforementioned definition and explained by the Parisian masters, plainly demonstrate that in no way can that definition be adapted to God, to angels, to accidents, or to the other things from which natural composites are neither generated nor composed. The first condition is that they are not made from others — the explanation being that since principles are contraries, as will be said below, and first contraries per se are not made from one another since they are simple (otherwise they would not be contraries per se), while secondary contraries are made from contraries, as Aristotle teaches at that passage. The second condition is that they are not made from one another — because they are contraries, and contraries are not made from one another, either as from a subject (since whiteness is not the subject of blackness) or as from a constitutive part (since blackness is not made from whiteness as from a constitutive part of it), although one can certainly be made from the other as a terminus a quo — thus from the non-white, white comes to be; and from the unmusical, the musician comes to be, as Aristotle testifies (*1. Phys. c. 5. T. 43. and following*). And if white comes from black, that is per accidens, as the same Philosopher adds there and the Parisian masters explain in that place. Through this distinction the apparent contradiction that seems to be involved in Aristotle's writings is removed — for at (*T. 43. c. 5.*) he says that contraries are not made from one another, yet below at (*T. 47.*) he concludes that all things are generated from immediate or mediate contraries. The solution, I say, is this: at (*T. 43.*) he writes that nothing is made from contraries as from a subject or as from a constitutive part — for form is not made from matter, since matter is not a constitutive part of form. But at (*T. 47.*) he asserts that all things are generated from contraries as from a terminus a quo, or from their privation — as he himself explains at (*T. 43–44. and following*). The third condition: "but all things are made from them." All natural composites come to be from the said principles — from privation indeed as from a terminus a quo, and from matter and form as from component parts. Therefore from the aforementioned definition of principles there are excluded God, angels, accidents, and all other things from which natural composites are neither generated nor composed.

Assertion. Physical principles are rightly defined as those that are made neither from others nor from one another mutually, but all things are made from them. So Aristotle (*cit.*), from whom Scotus (*9. Met. q. 14. § De aliis*) and the other Scholastics do not depart. Proved first: that definition is deemed suitable which explains the thing defined and possesses all the conditions required for it — as I set forth in the Epitome (*1. 2. q. 7. a. 2.*). Such is the aforementioned definition of principles, as is clear from the three conditions explained a little above. It is therefore a legitimate definition. Secondly, in it there are, as it were, a genus and

a difference — I say as it were, because things that are partial and incomplete cannot strictly participate in genus and difference, as I have noted elsewhere. The quasi-genus of physical principles is principle or principles, and the remaining words serve as a quasi-difference. Through these, physical principles are distinguished from all other principles. The aforementioned definition of them is therefore correct.

Objection I: Form comes to be from privation as from a terminus a quo, and from matter as from a subject — as I was explaining above. Therefore one principle comes to be from another, and so it is wrongly placed in the said definition that principles do not come to be from one another. This objection seems already to have been dissolved above, before the assertion. Nevertheless, for a richer treatment and on account of the multiplicity of responses that can be seen among our own authors, it is worth examining it more precisely. Suárez, Hurtado, and Arriaga (*cit.*) — following Toletus and others, whom the Parisian masters seem to have anticipated — respond that one principle comes to be from another in a different genus of principiation, as the instance proves, but not in the same genus of principiation — that is, form does not come from another form, nor privation from another privation, nor matter from another matter.

Against this: their response conflicts with Aristotle, who at the passage cited, giving the reason why principles are not mutually made from one another, says it is because they are contraries, and because first contraries per se are not made from one another per se since they are simple (otherwise they would not be first contraries per se). Secondary contraries are made from secondary contraries, Aristotle teaches at that same passage. Therefore, according to Aristotle, from the absolute primacy and primary contrariety it is clearly shown that principles are made neither from others nor from one another. Furthermore, when Aristotle's express meaning is plain, he is not to be dragged into another sense — and it is evident that the Stagirite says in explicit words that all things are made from those principles, as is clear from their definition. Therefore the principles themselves are not made. Moreover, (*c. 7. T. 64.*) we read: "It is therefore manifest from what has been said that whatever comes to be is always composite." And (*T. 82.*): "Matter is the primary subject of each thing, from which something — that is, a composite — comes to be." And (*7. Met. c. 8. T. 26.*): "Form does not come to be nor is it generated." And (*1. 8. of the same work, c. 3. T. 5.*): "It has been shown and established that no one makes the species or form; what is made is the composite." The same is read (*12. Met. T. 12.*) and confirmed by Scotus (*7. Met. concl. 22.*). If sometimes matter and form are said to come to be, the verb "to come to be" is used in a broad sense — as when it is said "from nothing, nothing comes to be" and "from night, day comes to be"; it is so taken (*1. Phys. T. 58. 64.*) where coming to be is attributed to privation. But in the proper and strict sense, only the composite comes to be — as is plainly evident (*1. Phys. T. 65.*) and in the other texts cited. The reason is that what properly

comes to be does so from a pre-existing subject; if, therefore, matter were to come to be, it would come to be from a presupposed subject, which would lead to an infinite regress — as Aristotle infers (7. *Met.* T. 26–27.) and (12. *ibid.* T. 12.) and as Veglia astutely notes (*vest.* 1. c. 17. n. 50.), and before him Bonetus (1. *Phys.* c. 3.). This twofold acceptance of the verb "to come to be" is gathered by Veglia at that place from the passages just cited, and from (1. *Caeli* T. 112.) and (121.), by which the present objection is well and fully answered — and it is lucidly conveyed by the Doctor (1. d. 3. q. 6. § *Tertia quaestio.* X.) and (2. d. 17. q. 1. § *Dimissa.* A.)

Again, the response of the moderns is shown to be invalid: for in the same genus of principiation one principle is in turn made from another — since form comes from privation as from a terminus a quo (as from a dark state luminous air comes to be), and from form as a terminus a quo privation comes to be (as from a luminous state dark air comes to be). Nor does it avail to say with Hurtado (*cit.*) that this occurs in a different order — namely, that in generation the terminus a quo is privative, while in corruption the terminus a quo is positive — for this does not remove the fact that in the same genus of principiation one principle is made from another, which is a terminus a quo from which change begins; and it is accidental whether the terminus a quo is positive or privative, provided the change begins from it. All the more so: if one principle is conceded to be made from another in a different order, since different change is thereby had, a different order is plainly involved — and it is plainly clear from the stated definition of principles that the particle "mutually" is placed there explicitly, which demonstrates just such a diversity of orders, and which is excluded from them by that very prefixed term.

Hence is also exploded the response of our younger Scotists (*at the end of q. 4.*), who, pressed by that argument, concede that in a different order and genus of acquisitive and depletive change, contrary principles are made from one another. But this contradicts Aristotle, who at the very beginning of (1. *Phys.*) proposes to treat of the principles of natural things; and at (c. 7. T. 68.) he concludes that he has handed down the principles of natural things to which generation belongs. And it is clear from (*ibid.* from c. 2. nearly to the end) that earlier philosophers were intent upon the same — for their opinions and arguments about the principles of natural generation and their number are recounted there, as the aforementioned moderns do not deny, both in the passage cited and in their exposition of the text. For corruption, and whatever principles it may have per se, are not intended by nature but per accidens — as Scotus testifies (2. *dist.* 1. q. 3. § *Ad 1. argum. principale.* L.). Tataretus adds (2. *Phys.* q. 1. *scib.* 1.) that corruption and depletive motion are not natural. I said "if it has principles" because such things do not deserve the name of principle, since nothing comes to be from them; on the contrary, something ceases — namely, the composite that is corrupted. Therefore the definition of principles, as commonly received, cannot be adapted to them, since in it the clause "all things

are made from them" is expressly placed. And so, without purpose and against the intention of the philosophers, those authors have devised principles common to both acquisitive and depletive changes — pressed by the opposing instance, abandoning true Aristotelian doctrine and embracing a new one, they tenaciously defend their given response.

Furthermore, the dissolution of Pontius (*disp. 31. q. 1. n. 6.*), who thinks our response is merely nominal, is made void. It is vain, I say, because our response is Aristotle's — the head of the Realists — and Scotus's — the master of the Franciscans — sufficiently fortified and defended by the reasons adduced above.

Objection II: Matter comes to be from integral and entitative parts, according to Scotus (*2. d. 12. q. 2. § Respondeo D.*). Therefore principles come to be from others. Confirmation I: Since matter is included in the predicament of substance, it consists of metaphysical degrees, which are genus and difference.

Confirmation II: Particular principles come to be from common ones.

Confirmation III: The body, which is the matter of the soul according to Scotus (*4. d. 11. q. 3.*), comes to be from other matter — for the body is composed of matter and form. Therefore principles are made both from others and from one another.

I deny the first part of the antecedent: since integral parts are quantitative parts, and quantity presupposes the substantial whole because it is its subject, consequently matter cannot be constituted from the parts of matter. To the second part I say that entitative parts are not principles from which a composite is generated — of the kind that the principles of which we are speaking are — but from which the material part is put together. Therefore, since only the composite is made from the said principles, and matter is created while form is educed or induced into matter itself, it is soundly deduced that those entitative parts are not the physical principles from which the physical whole comes to be. To Confirmation I: I say that although matter, as an incomplete substance, is reduced to the predicament of substance and is composed, as it were, from genus and difference — as will be clear in the next question — yet it is composed from them not physically but metaphysically, as the Doctor writes of the rational soul (*2. d. 1. q. 6.*). To Confirmation II: The answer is clear from the same distinction. For that is indeed true metaphysically but not physically. I add that just as from common physical principles come common physical composites, so from particular principles come particular ones — as from the principles of fire, fire; and from the principles of water, water — as the Parisians note in the present context. Although that definition does not apply to individual principles taken singly, it is not therefore to be considered unsuitable — since it presupposes them collectively, not individually — just as the definition of genus, which does not pertain to each species singly: for the species of which genus is predicated is not itself that which is predicated of many things differing in species in quiddity. To Confirmation III: I say that the organic body has the

form of corporeity subordinated to the soul, and therefore in that respect it stands as proximate and immediate matter, as the Doctor indicates there (*ibid.*) and treats at length (4. d. 11. q. 3.) — which is not what we are treating here; just as we are not treating of the matter of artificial things, but of prime and remote matter, which acknowledges no prior matter.

Objection III: The heavens, which are a natural body, do not come to be from the aforementioned principles. For since the heavens are ingenerable and incorruptible, they are not to be considered as made from privation and matter. Therefore the definition given above is not correct. Fonseca (*cit. sect. 2.*) — where the common translation has "are made" — renders it as "are." He meets the instance this way: the heavens have principles of constitution, which are matter and form, but not principles of generation, among which privation is included.

But the common translation is not to be abandoned in order to satisfy the argument. For at (5. Met. c. 1.), in the common and general description of principle — and Fonseca himself agrees — "are made" is read. And (1. Phys. T. 82.), similarly in the definition of matter, "are made" is written. And other not undistinguished writers observe that the Greek verb can extend to "are made," "are," and "consist of."

It can be responded, in the view of the Philosopher, that the heavens do not consist of matter and form, since they are a simple body — as the Doctor shows in both the Oxford and the Paris works. But in the common doctrine of the scholastics who hold that the heavens are composed of matter and form, the antecedent is denied. For although matter did not precede the form of the heavens in time, it did precede it by nature, and in that prior state privation was present as a principle from which the heavens can be said, as from a terminus a quo, to have been principiated. And that its form was educed from matter — or from that chaos which Theologians postulate as having extended to the empyrean heaven — the Doctor indicates (2. *ibid.* § *Secundum. D.*).

Article II. To Which Principles the Aforementioned Definition Applies.

In this article, three difficulties can be raised. The first is whether the aforementioned definition of principles applies both to intrinsic and to extrinsic principles, under which the four genera of causes are comprehended. The second is whether principles of generation and of composition are defined; and if of generation, whether precisely as generation or rather as mutation. The third is whether principles regard substantial and accidental generation.

First Note, from Scotus (1. d. 5. q. 2. § *Ideo tenendo. E.*) and (d. 2. q. 7. K.): generation in created things presents two things that are distinct from one another — namely, production and mutation. Production formally belongs to what is produced, which is the composite (7. Met. 26.); it is incidental to it that it

comes to be with the mutation of some part of the composite itself. Mutation, on the other hand, formally belongs to the act of the mutable thing, which passes from privation of form to form. But mutation always and necessarily accompanies production in the generation of natural things, on account of the imperfection of the productive power, which cannot confer the total being upon the terminus of the production without presupposing something of it that it transmutes to another part of the same — and in this way produces the natural composite. But if the agent were perfect and did not require matter from which or in which to act, and could produce the effect from and through itself, then there would be production without mutation — as is evident in creation, in which, on account of the perfection of God's creative power placing the whole in being at once, there is truly the character of production insofar as through it the terminus produced receives total being; yet in it there is not the character of mutation properly so called, insofar as mutation designates something now comporting itself otherwise than before — as the Stagirite writes (*6. Phys. 31.*).

Second Note: Aristotle sets forth several definitions of natural generation in different places of his doctrine, which I gathered in the book on generation (*q. 2.*); and in all of them mutation is placed, especially at (*5. Phys. T. 7.*), where it is expressly read: "Generation is a mutation from a non-subject to a subject." Therefore most, such as Rubiis (*1. de generatione c. 4. Tract. 1. q. 2.*), think that generation is essentially a mutation, so that it would be pointless to investigate whether Aristotle prescribes principles of generation or of mutation. But since the same Philosopher seems to abstract production from mutation — because he abstracts the simply productive power from the transmutative power, as Veglia shows with many arguments (*vest. 2. most of all c. 8. T. 31.*) from (*1. Caeli T. 100.*): "Something is immortal and divine, from which it has been communicated to others — to some more clearly, to others more obscurely — being and living" — for this reason some not unreasonably inquire whether in (*1. Phys.*) the Philosopher assigned principles of generation or of mutation.

Assertion I. Natural principles of generation are defined not precisely as production and action, but as mutation. This assertion is divided into three parts, signified by the Doctor (*ibid.*) and (*2. d. 12. q. 1.*). The first part is proved in the first article from Aristotle, who at the beginning of (*1. Phys.*) proposes to treat of the principles of natural science in general and reproves those who transcend them as speaking unnaturally (*ibid. c. 2. qq. 7–8.*); and at (*c. 7. T. 68.*) he concludes that he has handed down those same principles of physical generation and their number. And I, from the other definitions of principles that do not pertain to Physics, have sufficiently explained and established that first part. Nor is there anyone I have seen who appears to dissent from it.

The second part is indicated by Duns (*in 2. cit. contra Aversam q. 10. sect. 2.*) and Hurtado (*sect. 2. § 7.*), who comprehend under that definition every genus of cause. It is urged first: generation as production is transcendent, as it belongs to

the generation of the divine Word — as Scotus asserts (*ibid.*) — and to creation, which, being a making from nothing and presupposing no pre-existing matter, is not properly a mutation, but is nevertheless truly a production. The principles in (*1. Phys. T. 62.*), however, are defined as those from which natural composites come to be — either as from a terminus a quo or as parts composing the whole — as Aversa agrees (*alleg. sect. 1.*). Therefore they are not defined as principles of action and causation. Secondly: what abstracts from motion and mutation is not of physical consideration (*2. Phys. c. 2. and 12. Met. 6.*). Therefore principles of generation as action are not treated in this place. This Aristotle plainly intimates to us: at (*5. Met. c. 1.*) he presents another definition of principle general and congruent to all and singular principles — as is clear from the second note together with the prefatory passage of (*1. Phys.*) where he had premised a definition of the principles of generation, which always involves mutation. Again: the simply productive power does not pertain to Physics, as Veglia most recently notes (*vest. 2.*). Therefore production simply is not evaluated by Physics, as is evident in (*Met.*) at the passage just cited.

The third part follows from the two prior parts and is expressed by Aristotle (*8. Phys. T. 57.*) and elsewhere, who in defining generation always places mutation in its definition. Moreover, those three principles are found and proved to be present in natural generation through mutation. For since two principles are contraries and the third is their common subject, and impossibles are simultaneously in the same subject, it is necessary that mutation take place from the terminus a quo to the terminus ad quem — that is, from privation to form — for a new generation to be had. This the Stagirite shows at length and clearly (*1. Phys. T. 50. to T. 71.*); and before that, at (*T. 48.*), he intimates it in these words: "Those that are generated and corrupted come to be from contraries." Furthermore, at (*T. 78.*) he warns that those philosophers who posit other principles deviate from the truth. Then at (*T. 80.*) he reproves Plato who, among the number of said principles, does not place privation. Moreover, at (*T. 82.*) he defines matter as the common subject of every natural transmutation. Finally he concludes that those three, and no more and no fewer, are to be established as principles. The same is transmitted (*12. Met. T. 12.*). Therefore it is clear from Aristotle that the four genera of causes are excluded from the catalogue of natural principles, and that those are principles of generation not precisely as production is, but as it is mutation.

Assertion II. Principles both of generation and of composition are defined. This is deduced from Scotus (*ibid.*) and (*2. Rep. dict. 12. q. 1. § aliqui*), and it is opposed by our younger Scotists (*cit. q. 2. concl. 2.*), who think that in (*1. Phys.*) Aristotle treats only of principles of generation, and in (*2. Phys.*) of principles of composition. It is proved first from (*1. Phys. c. 6. T. 51.*): principles must always remain. For privation withdraws when form arrives — which, together with matter, constitutes the composite — and both persist in it until the composite itself is corrupted. And (*T. 60.*): "Some principles remain, others do not" —

which is to say: the principles of composition remain in the composite, but not the principles of generation, such as privation. Secondly: in the definition of them where the common reading has "all things are made from these," from the Greek text it is derived that "all things are" or "consist." This can certainly only be taken of principles of composition, since the whole that comes to be from the principles is not made from, nor consists of, privation, but only from matter and form. Thirdly: the Philosopher must discuss principles of composition in this place — both because at the beginning of (*1. Phys.*) he himself promises to treat of principles in general, and because he confirms this at (*T. 58.*), and at (*T. 66.*) he adds that privation is a principle per accidens, to which Scotus subscribes (*2. dist. 12. q. 1. sub 1.*) — which is plainly expounded of a principle of composition. Hence at (*T. 82.*): "For matter, that is, the remaining cause of those things that come to be, together with form, is a cause — just as a mother." But in (*2. Phys.*), where our moderns suppose him to be treating of principles of composition, he there reasons about matter and form as they are natures and causes, which they themselves candidly confess are not contained under the stated description of principles (*cit. concl. 1.*) — against Hurtado, cited by them. Therefore, in the aforementioned definition of principles, principles of generation and of composition are simultaneously captured.

Assertion III. Aristotle hands down primarily the principles of substantial generation, and secondarily the principles of accidental generation. This is gathered from the Doctor (*loc. pramem. § Ad argumenta sub I.*). It is proved first: those principles are described per se and primarily by Aristotle (*cit. T. 42.*) from which composites come to be per se and primarily — as is clear from those words: "all things are made from these." But substantial composites come to be per se only, as is read (*ibid. T. 62.*): "to become properly belongs to substance alone." Then to accident, as is shown beforehand at (*T. 58.*): "from one thing, another" — meaning, a substantial composite; "and from one, another" — meaning, an accidental composite comes to be. Again, (*8. Met. c. 1.*) and (*12. ibid. c. 3.*) substance is divided into matter, form, and composite; and it is there added that the composite is the third from these — that is, from matter and form — to which alone generation and corruption belong. Furthermore, the definition of matter (*1. Phys. T. 82.*) is accommodated only to prime matter, which is substance. Then the questions that are raised by philosophers in (*1. Phys.*) about the same principles of generation are raised most of all for substantial generation. Moreover, the composite is said to consist of nature — that is, of substantial form and matter, which is also nature (*2. Phys. T. 4.*). And very many other things are said about the same that can only be understood of principles of substantial generation. But whatever is adduced about accidental generation is said only for the sake of explanation and by way of consequence — since accidents are per se sensible, and through their knowledge we are led to the knowledge of substances, just as through artificial things we are led to natural things, the Philosopher furnishing this at (*1. Phys. T. 69.*). Furthermore, the

accidental composite is a being per accidens, which does not fall under science; and the object of Physics, as asserted, is the natural composite, which is substance. Finally, our moderns, against whom our assertion is directed, are compelled to confess this truth (*q. proaem. a. 1.*) in their responses to objections, saying that accidents pertain indirectly to Physics.

Objection: Against Assertion I — In natural generation two aspects are to be considered: the aspect of production or action, which regards the agent; and the aspect of mutation, which designates a subject passing from privation of form to the possession of that form. But the aspect of mutation is never mentioned throughout (*1. Phys.*); what is mentioned well is the aspect of action, under the word "to come to be" (*T. 43. and following*), or under the title of generation (*T. 68.*). Therefore principles of generation as action and production alone are given.

Confirmation I: Those are described as principles in that passage about which the Philosopher decrees he will treat at the beginning of the book cited; but it is his intention there to discuss principles, causes, and elements, from which principiation, production, and action proceed. Therefore those very things are the principles of generation precisely as production.

Confirmation II: Principles, as first things, exhibit primacy and origin, and involve no principiation by another — as Cicero testifies (*3. Tusc.*); otherwise they would not be first principles. Since, then, the stated definition is congruent to all principles, it is aptly inferred that they are considered as principles of generation and production, not of mutation.

I concede the major and deny the minor, as is clear from (*T. 68.*). For to carry out mutation, one contrary — whether present or absent — together with the other will suffice. And (*T. 78.*), and finally at the end of that book, he defines prime matter as the primary subject of every natural mutation; and privation, which is one of those principles, can only be a principle of generation as mutation. To Confirmation I: I concede the major; to the minor I say that the proposal there is to discuss principles not absolutely and universally — for he treats of these as such at (*5. Met. c. 1.*) — but of physical principles, as he himself explains in these words: "It is evident that natural science too must first define those matters that relate to principles." But physical principles involve mutation, as I have noted above. Nor does it matter that causes are also written there, since the term cause is not placed there so that the principles he will hand down comprehend the four genera of causes — since at (*12. Met. 12.*) he calls privation, which is truly not a cause, a cause; and three principles are assigned while four causes are counted; and causes precisely do not pertain to Physics but to Metaphysics, as can be seen (*5. Met. c. 2.*). To Confirmation II: I say that the universal definition of principle is found at (*5. Met. just cit. c. 1.*), which I examined above in Article I, Second Note. But here I adduced the definition particular to the principles of natural generation, which involves mutation.

Objection II: Against Assertion II — Aristotle at (*1. Phys. T. 68.*) concludes that he has provided the principles of generation, or those that are required for natural generation. Therefore only the principles of becoming are described there, which are principles of generation — and not the principles of being in fact, which are principles of composition.

Confirmation I: The same Philosopher there always considers matter insofar as it is the subject of transmutation, and form insofar as it is its terminus.

Confirmation II: The principles of composition are treated at (*2. Phys. T. 7.*) under the name of nature, and at (*T. 27.*) under the title of causes. Therefore in (*1. Phys. cit.*) they are posited only as principles of generation.

I concede the antecedent and deny the consequence — for he attributes both to them, as is clear from (*T. 51. 81.*) and at the end of that book. To Confirmation I: I say that there matter is considered not only as it is the subject of natural mutation but also as it is an intrinsic part of the natural composite. To

Confirmation II: I deny the antecedent, since in that place the discussion is about nature and art and their differences. And nature is there considered as it is the passive principle of motion and rest, which belongs both to matter and to form — in which way form is not the principle of the composite, nor a part of it. Likewise in that book the discussion is about causes insofar as they exert influence upon an effect, not insofar as they compose a whole as intrinsic and essential parts of it.

Objection III: Against Assertion III — One common univocal concept can be abstracted, equally congruent to substantial and accidental generation. Therefore in the stated definition of principles, both substantial and accidental principles are contained.

Confirmation: In no other place is another definition assigned congruent to the principles of accidental generation; therefore, lest Aristotle appear deficient, it must be asserted that all are included in it.

I concede the antecedent and distinguish the confirmation: equally primarily for substantial and accidental — I deny; primarily for substantial and secondarily for accidental — I concede. They are therefore called first principles because substance is the first being and the foundation of the others, while accident is said to be a being of being, inhering in a subject. To the Confirmation the same is to be said. For just as substance is treated directly and accident, which follows upon it, indirectly — so the principles of substance are treated first and the principles of accidents secondarily, as Aristotle (*ibid.*) has done.

Article III. How Many Natural Principles There Are.

Concerning natural principles and their number, the ancient philosophers are seen in Aristotle (*1. Phys. from c. 2. nearly to the end of that book*) to disagree, differ, and stammer to such a degree that one may rightly say of them: "as many heads,

so many opinions." It is tedious to recite and refute their opinions and dreams — since all of them have been recounted and rejected at length and admirably by Aristotle, and their wranglings so settled, convicted, extinguished, and buried that scarcely anyone has dared or been able to rescue them from oblivion. Therefore, the common doctrine of Aristotle on these matters, as solid and acute, is to be received and retained.

For the decision and confirmation of this difficulty, the distinction of principles into intrinsic and extrinsic, drawn by Aristotle (*5. Met. 1.*) and recalled by me in the two preceding articles, is relevant. Intrinsic principles are those that are intrinsically and formally required for the being or becoming of something — thus matter and form are intrinsically and formally required for the being of the whole composite, and privation together with matter and form for its becoming, and they are contained within it — the former as essential parts of the composite, the latter as the terminus a quo of its generation. Extrinsic principles are those that do not enter into the being of something, such as the efficient and final cause, which contribute neither to the generation of the composite nor to its composition. Intrinsic principles are further divided into principles of composition — which are required for composing the whole as its intrinsic parts, namely matter and form, and these are called principles in the state of being (*in facto esse*), so called because they remain in the whole after the whole is made and as long as it persists in being — and into principles of generation, such as privation, which, beyond the two aforementioned principles, are required for the generation of the whole. These are called principles in the state of becoming (*in fieri*), because they are necessary for the making of the whole, even though not all of them remain in the whole itself — such as privation. Therefore privation is called an intrinsic principle — not of composition, since it withdraws from the composition of the natural thing when form arrives, but of generation, because it is the terminus a quo and the intrinsic terminus of natural generation. Likewise, privation is called a principle per accidens of composition, or with respect to the being of the thing; and a principle per se of generation, or with respect to the becoming of the thing.

Assertion I. Only three principles of the generation of natural things are numbered — namely, matter, form, and privation. So Aristotle (*1. Phys. c. 6. T.*) and (*12. Met. T. 12.*), and Scotus in both works (*2. d. 12. q. 1.*). It is proved first: natural generation is necessarily a mutation, which is the passage from non-being to being (*5. Phys. T. 7.*). Mutation, however, requires three things — a terminus a quo, which is privation; a terminus ad quem, which is form; and a subject of both, which is matter, which passes from not-having a form to having a form. Therefore only three principles of natural generation are established. Secondly: there are two contrary principles — form and its privation — as will be proved in the next article. Beyond those two, there is decreed a common subject of both, which is matter. For contraries share the same subject, even though they are not simultaneously compatible with one another in it.

Therefore three are the natural principles previously enumerated. Thirdly: there are as many distinct natural principles as there are distinct natural modes of principiating; but there are three diverse natural modes of principiating — therefore also three natural principles. The major is evident. The minor is ready at hand: privation principiates as terminus a quo and by way of rejection; form principiates as terminus ad quem; and matter as the receptive subject of both. Therefore there are so many principles — neither more nor fewer — as have been enumerated above.

Assertion II. There are only two principles of natural composition — namely, matter and form. So also Aristotle (*cit. c. 7.*) and Scotus (*ibid.*), and he intimates as much (*1. Post. q. 57. § ad 1. arg.*) and (*7. Met. q. 10. § Ad 1.*). It is proved first: there are only two principles that intrinsically and essentially compose the whole and make one thing per se (*2. Anima T. 7. and 8. Met. T. 15.*). Therefore there are only two principles of composition. Secondly: there are as many essential principles and intrinsic parts of the whole as there are things into which the whole is resolved — for the same things are compositive and resolute principles, as is evident (*1. Prior.*), from which that saying is derived: "that from which something consists, into that it is resolved" — as a man is composed of body and soul, and is resolved into body and soul. But there are only two aforementioned constitutive principles of the physical composite — therefore there are only two principles of composition. Thirdly: there are only two contrary principles — as the ancient and modern philosophers agree (*1. Phys. T. 48.*) — simultaneously impossible in the same subject — namely, form and its privation. But in the persisting composite, privation does not exist — for while form exists in it, privation is absent from it. Moreover, whatever is a positive being and a complete substance consists of positive principles, which privation is not. Therefore only the two aforementioned principles of composition are established.

Objection I: That upon which something essentially depends in its becoming is its principle — as is noted from the broad and narrow definition of principle given above. But the physical composite essentially depends not only upon those three aforementioned principles in its becoming, but also upon an agent, without which it cannot be produced. Therefore, beyond those three, a fourth principle must be admitted — namely, the agent.

Confirmation I: The potency of matter, its quantity, and the prior dispositions toward the production of the composite are required; therefore they are its principles distinct from the other three.

Confirmation II: For the constitution of the composite, beyond matter and form, the union of both is necessary — which I shall show (*q. 4. of this book*) to be something distinct from both simultaneously united.

Confirmation III: The whole is also composed of substance; therefore there are more than three principles of natural generation.

I concede the major and distinguish the minor: the composite depends upon the agent as its extrinsic principle — I concede; as its intrinsic principle — I deny. For here, with Aristotle, we are speaking of the number of intrinsic principles. Moreover, as has been proved in the preceding article, it remains established that the definition of principles is to be accommodated not to generation as production and action, which regards the agent, but as it is mutation — which includes neither agent nor action in its definition.

One might press further: privation is an extrinsic principle since it does not enter into the composition of the whole. If therefore the efficient cause is removed from the number of principles because it is an extrinsic principle, then privation too is to be exempted from their catalogue. The parity is to be denied — because although privation is an extrinsic principle of composition, it is nevertheless an intrinsic principle of generation, which is a mutation from non-being to being (*5. Phys. T. 7.*).

One might urge further: the terminus a quo and the terminus ad quem are extrinsic to motion — since motion formally is a relation, as will be said (*1. 8. q. 1.*), which arises from posited extremes, and therefore accrues to it from without. But privation is the terminus a quo of natural generation; therefore privation is an extrinsic principle, both of composition and of generation. One must respond that privation is called an intrinsic principle of generation not constitutively, but terminatively — which is to say that generation necessarily requires a terminus a quo, which is privation of form, in order that a new composite may be generated.

To Confirmation I: I say that the potency of matter is really identified with matter itself; therefore it does not constitute a principle distinct from matter itself. The other things required on the part of matter cannot be called a principle per se, but rather appendages of a principle. Especially since quantity and the other accidents are not primarily subjects in matter but in the composite — as I shall show (*1. 5. q. 1.*).

To Confirmation II: I say that for the construction of the composite, union is indeed required, not as its principle, but as the bond of its constituting principles — in much the same way as in Logic the verb is the copula of subject and predicate and is not numbered among the terms, as I showed in the Epitome (*l. 1. art. 2. q. 1.*).

To Confirmation III: Arriaga (*disp. 1. Phys. at the end of sect. 2.*), pressed by this instance, concedes that subsistence is a principle of the composite in reality, but not in the opinion of pagan philosophers, to whom subsistence was unknown. He therefore thinks the dispute about the number of principles is merely verbal. But on account of so slight an argument, one should not depart from the

common position of philosophers; and without any compelling necessity, no other principle distinct from the aforementioned three is to be introduced. Otherwise Arriaga himself should multiply other principles — such as existence, which differs from subsistence — since the divine Word indeed assumed a humanity that existed but did not subsist in itself. Nor does subsistence deserve the name of principle; on the contrary, it is rather a terminus, since it terminates and completes a substantial nature, as Arriaga himself asserts (*disp. 4. Met.*). For subsistence follows upon matter and form united and upon the composite made from them, of which it is the terminus and complement — especially in the view of Arriaga, who does not admit partial subsistences of matter and form. Again, subsistence is not a thing but a mode that accompanies the thing whose mode it is, as I shall show in the Metaphysics against the aforementioned Arriaga. Therefore to the argument I deny the antecedent — both because the subsistences of matter and form are partial, following upon them as modes follow upon the things they modify; and also because the total subsistence, which belongs to the whole composite, likewise follows upon the whole, since it is its ultimate terminus.

Objection II: From (*1. Phys. c. 6. T. 50.*): principles must always remain. But privation does not always remain, since it withdraws at the arrival of form. Therefore privation is not to be numbered among the principles of natural things — and so the previously adduced triad of principles is not to be accepted.

Confirmation I: What exerts no influence upon a natural thing is not its principle, since a principle principiates by exerting influence upon what is principiated. But privation exerts no influence upon the natural thing because it is a non-being. Therefore in no way is privation to be placed among the principles of natural things.

Confirmation II: If privation is conceded to be a principle because it precedes the composite to be generated, then a fourth principle must likewise be admitted — namely, the departing form, which equally precedes the composite to be generated. But this is not numbered among physical principles; therefore neither is privation.

I respond that the Philosopher is to be expounded as speaking of principles of composition and of disparate things, which persist in the composite as long as the composite endures — not of principles of generation, such as the contraries, of which privation is one.

To Confirmation I: I say that the major holds of principles per se and intrinsic to the composite itself — as Aristotle testifies (*1. Phys. T. 66. 75. and 77.*) and Scotus (*2. d. 11. q. 1. infra I.*).

To Confirmation II: I deny the consequent of the major. For that is per accidens — because if the preceding form did not depart (which many think is possible by divine power), then the form to be expelled would assuredly not be a

principle. But privation is always prerequisite for the new generation of the composite as the terminus a quo. And upon the arrival of the new form, privation itself withdraws. Therefore privation, and not the departing form, is established as the principle of natural generation. This is deduced from Aristotle (5. *Phys. T. 7.*) and Scotus (*q. 4. prol. § contra hoc.*) and (2. *d. 1. q. 5. at the end.*).

Objection III: Those three principles are not coextensive with natural generation. For they apply to the creation of Adam, which cannot be called natural generation. Nor do those same principles intervene in every generation. For if a consecrated host putrefies and from it a worm is generated, then there will be true generation with no pre-existing matter from which as from a material principle such a worm is produced — because according to faith, in that host there is no substance of bread, but only its accidents remain, divinely sustained. Therefore the triad of principles is neither coextensive with natural generation nor necessary to it.

I respond: the procreation of Adam, even if considered extrinsically — that is, with respect to God who creates — is said to be supernatural; nevertheless intrinsically it is natural, since truly three natural principles intervened in it. Just as the sight restored by God to a blind person is supernatural — because it comes from God acting supernaturally to illuminate the blind — yet the illuminated blind person sees naturally, and his vision is natural, as Scotus writes (3. *d. 14. q. 2. § In quaest. infra C.*) and in the Paris Reportatio there.

To the other instance about the consecrated host I say, given the hypothesis that the accidents of that host are unable to attain to the production of a substance — nor can any natural agent do so — God, who can supply every causality of a secondary cause and immediately perform what that secondary cause cannot accomplish, would create a new matter, and a new composite substance congruent with those accidents disposing toward its production. And so from the consecrated host a worm would be generated — as Scotus agrees (*Quod. 10. § Ad argumentum principale.*) and (4. *d. 12. q. 6. § Dico D.*), and Vorrlong and Orbellus there.

One might say: the aforementioned production or generation is not properly a mutation, as the Doctor teaches (2. *1. 5. q. 2. 1.*) and (3. *d. 2. q. 3. E.*), (*d. 7. q. 2.*), and (4. *d. 43. q. 5.*); and from what has been said, those principles exist under the character of mutation. Therefore the given response is invalid. I say: although such a production is not rigorously a mutation in the sense the Philosopher takes it — who acknowledged things to be generated only in the ordinary course — nevertheless it does not seem to be exempt from the series of mutations, as the Doctor intimates (4. *d. 11. q. 1.*).

Objection IV: A principle is prior to that of which it is the principle, as its common etymology and definition indicate. But form is not prior to generation, since it is its terminus ad quem. Therefore neither is it its principle. Pontius

(*disp. 31. q. 2. concl. 2. n. 14.*), pressed by this argument, concedes that form is not a principle of natural generation. But this conflicts with the torrent of philosophers who teach three principles in fieri and two in facto esse; and with the truth, since, generation being truly a mutation, it requires three principles. For the passage cannot be effected through the subject, which is matter, unless it begins from the terminus a quo, which is privation, and is directed toward the terminus ad quem, which is form — as is sufficiently clear from what was said above. So the triad of principles is not to be denied.

Suárez (*disp. 12. Met. sect. 1. n. 9.*), to whom Hurtado adheres (*disp. 1. sect. 2. § 1.*), responds that form is prior to generation in the order of intention, but not in the order of execution. Against this: the order of intention pertains not to the formal but to the final cause. But to posit the final in place of the formal is to exclude the formal and include the final, and to introduce extrinsic principles — which are the efficient and final causes — and to reject the intrinsic principles, which are matter and form; which is false. Moreover, the composite is prior in intention even to form, since it is the total terminus and ultimate end of the latter, while it is posterior in execution. Now it is a common maxim of philosophers that what is posterior in execution is prior in intention. Yet no one until now has dared to assert that the composite is a principle in intention — since in truth it is the principiated thing and is composed from principles. Therefore form as prior in intention should not be considered a principle of generation.

My response, then, is this: just as matter is prior to generation because it is the subject in which generation itself is subjected, so too form is prior to generation — both because generation is formally a relation, according to Scotus, which presupposes two extremes from which it arises, and also because generation is the way to the composite, of which it is properly the generation, as Scotus says in the Paris Reportatio (*2. d. 8. q. 1. § Dices.*). For that reason generation, which is ascribed only to the whole, presupposes its principles, among which form is counted. Therefore form is truly called a principle of natural generation.

Article IV. Whether Principles Are Contraries.

The affirmative part is supported by authority and by reason — by authority of the ancient philosophers, who, whether they posited one or many, finite or infinite principles, with one accord register that principles are contraries (*1. Phys. c. 5. T. 48.*); then by reason: because what comes to be passes from non-being to being, that is from privation to form; and privation and form are contraries. Then by truth — because, as is read there, those philosophers were compelled by truth to assert this. The negative part, though it was formerly utterly abandoned and despised by all as false, now has some patrons who approve and celebrate it as true — among whom Aquarius and Aversa are cited by our moderns (*disp. 1. q. 5.*).

First Note, from Aristotle (*5. Met. c. 10. T. 16.*) and Scotus (*q. 14.*) and (*23. univers.*): contraries are taken in two ways. First, properly — thus they are defined as things that, under the same genus, mutually expel one another from the same subject, such as the primary qualities, about which Antonius Andreas (*10. Met. q. 6.*) and I at length (*Log. l. 3. q. 9. a. 5.*). Second, improperly — for those that are repugnant and do not simultaneously coexist in the same subject; in this way contraries are called a habit and its privation. For while form exists in matter, its privation cannot simultaneously be in the same matter. Thus the philosophers speak in the present context when asserting that principles are contraries — where Averroes, expounding Aristotle, uses the name of contrariety as extending to privatively opposed things, and to the differences of any genus (*10. Met. T. 23.*). For every genus is distributed into two differences of unequal perfection — the more perfect designated by the name of habit, and the less perfect by the name of privation — as is clearly stated of the differences of animal, one of which — namely rational — stands as a habit, and the other — namely irrational — stands as a privation.

Second Note: since substance is called being simply, because it is a being subsisting per se and prior to accident in nature, time, and definition (*7. Met. 1.*), and accident is called being in a qualified sense, because accident receives its being from substance, inheres in it, and is sustained by it — and is therefore said to be a being of being — it follows that there is a twofold contrariety: one between a substantial form and its privation, called contrariety simply and primarily; the other between an accidental form and its privation, called contrariety in a qualified sense and secondarily. This twofold contrariety is intimated by Aristotle (*10. Met. c. 7. T. 15.*) in these words: "The first contrariety is that of habit and privation — not every privation, however, but that which is perfect." The other contraries are said according to these. Note further: some contraries are contraries in themselves totally, or per se primarily and adequately — such as the form of a man and its privation; while others are contraries not in themselves totally but by reason of parts, or inadequately — such as a man and a non-man. A man is contrary to a non-man because a man has a form which the non-man lacks. Those that are contraries in themselves totally, or by reason of parts, are called per se contraries. Those that are contrary neither through either taken as a whole nor through anything added to them are called contraries per accidens. So that the opposition between form and its privation may be fully evident:

Third Note: there is a triple substantial mutation. One is purely depletive, in which form is cast off and nothing positive is acquired — and the form to be cast off is the terminus a quo of this mutation, and its privation is the terminus ad quem. Another is purely acquisitive — in this nothing is lost, but something positive is acquired — and the terminus a quo of this is the privation of the form to be acquired, and the terminus ad quem is the possessed form. The third is both acquisitive and depletive simultaneously, which has two forms and two

privations corresponding to the two aforementioned mutations. For there is the privation of the possessed form, which is contrary to the possessed form; and there is the privation of the form to be possessed, which is contrary to the form to be possessed. Therefore in every mutation there is always the contrariety of form and its privation, and the termini of every mutation are privatively opposed — one of them being lost, the other acquired.

Assertion I. The principles of natural things are contraries. So Aristotle (*1. Phys. c. 5. T. 42.*) and Scotus (*ibid.*) and (*2. d. 1. q. 2. § Respondeo sub A.*). It is proved first: those are contraries which cannot simultaneously be in the same subject — as is clear from the first note. But the natural principles, in the same subject or in the same matter, do not simultaneously coexist: for privation withdraws from matter upon the arrival of form, and conversely. Therefore physical principles are rightly established as contraries. Secondly: the termini a quo and ad quem of mutation are contrary, as is evidently seen in the termini a quo and ad quem of local motion, which are impossible with one another in the same subject (*5. Phys. T. 26.*). For otherwise the mobile would not move from one place to another unless it left one ubi from which the motion begins and acquired another ubi in which its motion ends. But one of the natural principles is the terminus a quo of natural generation — namely, privation — and another is the partial terminus ad quem — namely, form, as is clear from what was said above. Therefore principles are rightly established as contraries.

Assertion II. There are only two contrary principles — form and privation. The Doctor holds this (*cit.*) from Aristotle (*1. Phys. c. 7. T. 67.*), taking it as indefinite — just as that which is read (*ibid. T. 50.*): "principles always remain" — meaning not all, but only two, namely matter and form. And (*2. Phys. T. 30.*): "Causes are causes of one another" — meaning not all, but only the efficient and the final, as Lychetus explains (*2. d. 12. q. 3.*). And (*1. Post. c. 3. T. 6.*): "Of certain things there is demonstration; of others there is not." It is proved first: things that are impossible with one another share a common subject in which they cannot simultaneously exist, as is clear of proper contraries that mutually expel one another from the same subject. But the natural principles, as proved in Assertion I, are contraries that share a common subject — namely, matter — in which they exercise their contrariety and conflict. The receptive subject of contraries, since it is not itself contrary to the others and is posited as one of the principles, plainly leads to the deduction that there are only two contrary principles. Secondly: every mutation requires two termini — a quo and ad quem — which are impossible in the same subject in which the mutation occurs, as I explained in the Third Note. But those two termini are the two initial principles of natural generation — namely, privation and form. I add: contraries cannot simultaneously enter into the essence of something, since they conflict and destroy one another. Therefore, since the composite is constituted in being from principles, it is necessary that one contrary depart — which is privation — and the other remain for its composition — which is form,

which together with matter makes up the physical whole. Consequently it is established that there are only two contrary principles as aforementioned.

Assertion III. The principles are first contraries. Aristotle transmits this (*1. Phys. c. 5. T. 42.*), from whom the Doctor (*ibid.*) does not deviate. It is urged first from what was proved in Assertion I: principles are contraries; but they cannot be anything other than first contraries, since they are defined as those from which, neither from others nor from themselves mutually, but from which all things are made. Therefore principles are first contraries. Secondly: privative contrariety is broader and more common than the other contrarieties, to which even positive ones are reduced — since one is more perfect than the other (e.g., heat compared to cold), which designates the privation of the perfection of the other, as Aristotle brilliantly sets forth (*10. Met. T. 16. sum. 2. c. 3.*). Again, since this contrariety exists between substance and its privation, and substance is being simply and the first predicament, it is plainly deduced that it is the first of all contrarieties. Hence Aristotle (*7. Met. c. 1.*) asserts that substance is prior to every accident in time, in nature, and in definition, since it is their subject, base, and support.

Assertion IV. Primary contrariety per se primarily belongs to the substantial form and its privation, and secondarily to the accidental form and its privation. This assertion is consonant with and consequent upon the third assertion, which I placed above (*art. 2. of this q.*), and it is gathered from Scotus (*ibid.*); and it militates against two of our more recent Scotists (*disp. 1. q. 5.*). It is proved first from Aristotle (*cit.*), who, treating primarily in this context of the principles of the substantial composite, says at (*T. 51.*): "from non-substances, substance does not come to be." Therefore in that place, primary contrariety is treated first, and subsequently the contrariety of the principles of the accidental whole. Hence the Philosopher at (*10. Met. c. 7. T. 15.*) explicitly adds: "the first contrariety is that of habit and privation — not every privation, however, but that which is perfect." And at (*T. 16.*) he urges that all things come to be from contraries and that contrariety is found in every genus — plainly suggesting this. Since, therefore, substance is the first genus, the first contrariety is without doubt adapted to it. Secondly: generation properly belongs to the substantial composite — from Aristotle (*7. Met. T. 22. and following*) and Scotus (*1. d. 3. q. 6. § Tertia quaest. sub X.*) — and our said moderns near the end of (*q. cit.*) candidly confess from (*T. 50.*) of the first Physics that first contraries are in the genus of substance. Therefore, per Aristotle, the first contrariety is not equally and adequately attributed to both the substantial and the accidental form and the privation of each.

Objection I: Against Assertion I — Aristotle at (*1. Phys. T. 47.*) subjoins that principles are contraries because everything that comes to be comes to be from a contrary. But what comes to be from another is not a principle but a principiated thing, or a composite. Therefore a principle is per se contrary to the principiated thing, and principles are not contrary to one another.

Confirmation I: The terminus a quo is contrary to the terminus ad quem, as is clear from what has been said. But the principiated thing is the terminus ad quem. Therefore contrariety exists between a principle and the principiated thing, not between principle and principle.

Confirmation II: A terminus a quo is found also in the making of non-physical things — for an angel comes to be from the non-being of the angel as from a terminus a quo. And if this is admitted, anything will come from anything — which conflicts with Aristotle (*cit. T. 43.*). Therefore it must be asserted that principles per se and directly are not contraries.

I respond: that assertion subjoined by Aristotle is to be interpreted not per se primarily of the total terminus a quo, but of the partial terminus a quo — as remains explained in the Second Note. And such is the express meaning of the Philosopher (*cit. T. 45.*), saying: "The musician comes to be from the non-musician — but not from just any non-musician, but from that in which there is the privation of music." And (*T. 46.*): "Figures come from the privation of figure." Thus the non-musician is not per se primarily and adequately contrary to the musician, but by reason of the privation that is in the non-musician and that is contrary to music in the musician. And so principles are per se and adequately contrary to one another; and principiated things are contrary not in themselves totally, but by reason of the principles themselves — just as in positive contraries, not the very subjects of contrary qualities are per se primarily contrary, but the contrary qualities themselves — e.g., heat and cold per se primarily conflict with one another.

To Confirmation I: I say that the partial terminus a quo, which is privation, is precisely contrary to the partial terminus ad quem, which is form — but not to the total terminus ad quem, which is the principiated thing or composite.

To Confirmation II: I say that in creatables and non-physical things the terminus a quo is nothing, or a negation; while in generable and mutable things the terminus a quo is a privation. Therefore it does not follow that anything can be made from anything — since each form has a privation precisely opposed to it, from which as terminus a quo generation begins, as the Stagirite clearly sets forth (*ibid. T. 43.*).

Objection II: In the generation of a symbolic element from a symbolic element, the symbolic quality that was in the corrupted body persists in the generated body (2. *de gen. T. 34.*). Therefore the transformation of symbolic to symbolic is easier than that of non-symbolic to non-symbolic. Therefore principles are not contraries. And this may be confirmed when from red or white wine, vinegar is made — for from red or white there comes red or white, since the redness that was in the red wine and the whiteness in the white wine persist in the vinegar, which is red or white. Likewise from a shaped thing comes a shaped thing. Therefore not every generation has contrary principles.

I respond: in the said generation, not the same numerical but the same specific quality persists in the generated thing — since an accident does not migrate from subject to subject. But this must be examined precisely in the book on elements. To the Confirmation I say that this cannot happen, but occurs per accidens. For per se, from non-vinegar, vinegar comes to be; but per accidens, from red comes red, from white comes white, and from shaped comes shaped — as the Stagirite asserts in a similar case (*1. Phys. T. 43. c. 5.*), and the Doctor agrees (*2. d. 1. q. 3. § Ad 1. and q. 5. at the end.*).

Objection III: If it were possible by nature's powers to produce something tending toward a pre-existing thing — whether through the transmigration of souls from body to body of different species, as the Pythagoreans held, mentioned at (*1. Anima T. 53.*) — or of the same species, which Ferchius indicates Aristotle did not reprove (*vest. 6. 1. 2. n. 127.*) — this could be illustrated by circular motion beginning from one point and ending at the same point from which such motion began. In this way that circulation would have no contrary termini; and therefore natural principles need not be contraries.

Given the hypothesis, there would be a new generation and a new generated thing, because matter would pass from one form of which it was deprived to another form by which it was informed — in which case principles would always be found to be contraries. Regarding the example of motion: I say that circular motion returns to the same specific point and ubi, but different numerically. But more on this in the book on motion.

Article V. Whether Principles Are Univocated.

I discern in this article the opinions of the philosophers differing from one another. One is that of two recent Scotists (*disp. 1. Phys. q. 1. concl. 2.*), from whom Fuentes (*ibid. q. 3. art. 3.*) is not far distant, who think that the three aforementioned principles share a common univocal account of principle. Another is that of Fonseca (*5. Met. c. 1. q. 5. sect. 1.*), Suárez (*disp. 12. Met. Sect. 1. n. 13.*), and Pontius (*disp. 31. q. 2. Quaest. 1.*), who think that principle is analogous to them. The third must be the common position of Scotists — notably the Formalists (*art. 1. Tract. of theirs*) — who teach that being and non-being, real and of reason, have nothing univocal in common. For since privation is not properly a being, while the other principles are positive real beings, it follows that principle is equivocal to the three of them. Hurtado agrees (*disp. 1. sect. 2. § 17.*), as does Arriaga (*ibid. at the end of sect. 3.*).

The acceptations and definitions of principles adduced and expounded in Article I of this question are to be reviewed. For even if the word principle appears to have been imposed by the Ancients most of all to designate the beginning of motion and of time — which is more known to us and more sensible, and more suited to representing and making things — and for this reason they posited and distinguished beginning, middle, and end. This

Aristotle not obscurely intimates (*5. Met. c. 1.*), where in enumerating the various senses of principle, he begins from that from which motion begins — as his expositors note there. Nevertheless it receives many other significations and extends both to real beings and to beings of reason; to positive and to privative; to per se and per accidens; as well as to created and uncreated. For this reason one may doubt whether principle, with respect to all these, can be said to be univocal, analogous, or equivocal.

Again, principle can be considered in two ways — formally, that is, for the relation of a principle, by which it is formally called a principle and regards the principiated as a relative regards its correlative; or materially, that is, for what is the foundation of this kind of relation and is denominated a principle through it — as I showed in the Treatise on God as Triune (*disp. 4. q. 7.*), where I proved that principle in the immanent divine relations is indeed univocal with respect to the essential, notional, and personal; but principle in the immanent and in the transitive sense by no means so — since the former formally is a positive real relation, while the latter formally is a being of reason. But that to real being and to being of reason nothing univocal is common, the Doctor expressly teaches (*1. dist. 2 q. q. un.*), followed by Vorrlong and Orbellus there, and others — except Bonetus (*1. Met. c. 6.*).

Assertion. Matter and form are univocated in the account of principle, but privation is not. This assertion contains two parts, which are indicated by Scotus (*just mentioned.*). The first part is urged first: matter and form are positive real beings exerting real influence upon the composite and constituting it — therefore without doubt these two principles are univocated in the common account of principle. Secondly: both are natures (*2. Phys. T. 11.*), incomplete and partial substances (*ibid. T. 21.*), and two intrinsic causes (*ibid. T. 28.*); and moreover the aforementioned definition of principles most fittingly applies to these two. Therefore these two are univocated in the common account of principle.

The second part is shown first from Aristotle (*1. Phys. T. 66.*) and (*T. 75.*), asserting that privation is a principle per accidens; and (*2. Phys. T. 15.*) and (*5. Met. c. 4.*), where in listing natures he does not place privation among them. Secondly: to being and non-being, nothing is univocally common — as the Formalists cited above urge from Scotus. But matter and form are positive real beings, intrinsic parts composing the whole; while privation is a non-being (*1. Phys. T. 75.*). Therefore principle does not apply univocally to those three principles. Thirdly: either they are univocated in real being, or in being of reason — since there is no middle between real being and being of reason. But they do not agree in either: not in real being, because real being is not determined or contracted by non-being, such as privation (*from the passage just cited*); nor in being of reason, because real being is not contracted by being of reason — otherwise the difference of real being would be a being of reason, which implies a

contradiction. Fourthly: if what seems more to inhere does not inhere, neither will what seems less to inhere — as is evident in the Epitome (*l. 3. q. 3. a. 4.*). But real being and being of reason seem more to agree than positive being and privative being, since the former participate in their own manner in the account of being, while the latter do not at all. For if privative being were superior, it would be included in positive; and if positive were superior, it would be included in privative — which is repugnant. Finally: either these principles are univocated by reason of the formal being of principle, which is relation, or by reason of its fundamental being, which is the nature and essence of the said principles. Not the first — because the formal account of principle for matter and form is a real relation, while the formal account of the principle of privation is either nothing or a being in a qualified sense; and it is already evident that to being and non-being, positive and privative, nothing is univocally common. Therefore the account of principle is equivocal to the three enumerated.

Hence Fuentes is refuted, who at (*q. 3. of this book a. 3.*) — although he tasted these reasons at (*n. 5.*) — yet at (*n. 6.*), distorting the terminology of Scotus (as one may see at (*3. d. 7. q. 1. § Quarto. C.*)), writes that principle is indeed not a univocal predicate, yet is univocally predicated of the aforementioned three. But he is surely mistaken — because since to be predicated univocally means nothing other than to be predicated essentially, and nothing essential can be common to matter, form, and privation for the reasons adduced above, it is evidently concluded that principle is neither a univocal predicate (which he concedes) nor univocally predicated of them (which Fuentes himself asserts). Nor does it help him to say that principle stands to real and rational being as the knowable does — which he supposes to be univocally predicated of these; or that opposition is said univocally of being and its privation. For just as being that abstracts from real and rational being is not univocal in the school of Scotus, so neither is the knowable that abstracts from the knowable of real and rational being univocal — since a property, such as knowability, enjoys no greater privilege than that of which it is the property. And what he adds about opposition — it is evident that it is equivocal, just as man is said equivocally of the living and the dead, and of the real and the pictured, as is evident (*1. Predicam. c. 1.*).

Objection I: The same reason that is adduced by the Doctor (*1. dist. 3. q. 2. B.*) to urge the univocation of being, is the one that can be adduced to introduce the univocation of principle with respect to the three aforementioned. For someone may be certain that privation is a principle, and doubt whether it is a principle in the manner of a terminus a quo or in the manner of a terminus ad quem. Such a common concept of principle is quidditatively included in each of the singular principles; therefore principle is univocal to them.

The parity is to be denied — because being, which Scotus (*cit.*) posits as univocal, is positive real being, which is univocally predicated of God and creature, of substance and accident. But principle with respect to those three is not a positive real being; therefore they are not univocated in this.

Objection II: Privation is a principle of generation just as matter and form are, and the aforementioned definition of principles is rightly adapted to it. Therefore just as privation is not exempted from the definition and number of principles, so neither is it expunged from the univocation of principle.

Confirmation: From (*1. dist. 23. q. 1.*) — the infinitating negation is accommodated both to positive, privative, and negative, and even to the impossible. But a person, according to Scotus, presents the negation of communicability as quo and as quod, univocally predicable of its inferiors. Therefore, even though privation is not a positive being, it is not thereby excluded from the univocation of principle.

I respond: privation is indeed a principle of generation, yet it is not univocated with the other positive principles — even though the common description of principles applies to it. Just as equivocals are described by a common description at (*c. 1. Predicam.*). Nevertheless it does not follow from this that equivocals are univocal through it, since they agree in name and not in reality.

To the Confirmation: if that most improper univocation is admitted, the parity is to be denied — because all those things are negative and agree in a common negation. But that positive, privative, and negative should be univocated in something common to them is not to be tolerated.

Objection III: Aristotle (*12. Met. c. 4. T. 19. 23.*) expressly asserts that principles share an analogous account of a common principle. Therefore in this kind of common account of principle, principles are not equivocated.

I respond by granting that principles are analogous equivocals, not analogous univocals, nor something distinct from either — but all analogues are to be reduced to one or the other — as I showed in the Logic (*l. 3. q. 1. a. 7.*). And thus the testimony of Aristotle just adduced is expounded.

Article VI. Whether Anything Comes to Be from Nothing.

Three propositions are set forth from Aristotle (*1. Phys.*) which, as Bonetus notes and examines (*1. Phys. c. 2.*), appeared to the ancient philosophers to be true and self-evident. The first is found at (*T. 41–42.*) and (*12. Met. 6.*): principles are contraries. The second is read (*ibid. T. 52–53.*) and (*1. Caeli T. 120.*): beyond the two contrary principles, a third must be posited, which is their common subject, from which everything that comes to be comes to be. The third is written (*at the same place T. 64.*) and (*7. Met. 26.*) and (*8. ibid. 3.*) and (*12. T. 12.*) and elsewhere: everything that comes to be or is generated is composite. The first two have already been discussed by us — the first in Article IV of this question, and the

third in Article I in the response to the first objection. It now remains to investigate the second — not indeed whether there is a common subject that is the receptive matter of all forms (for this we reject in the following question, Article I) — but whether everything that comes to be does so from that third thing, or whether something comes to be from nothing. And certainly, speaking naturally, Bonetus (*alleg.*) adds that the proposition "something comes to be from nothing" terrified all philosophers and seems to be an implication of terms. Yet some, according to Averroes — and most recently Ferchius (*vest. 1.*) endeavors with many arguments to show — hold that it is true both in the doctrine of the Philosopher and in the reality of the matter, and that the contrary is false.

First Note, from (*1. Phys. T. 33–34.*), (*1. de gen. T. 11–12.*), and (*11. Met. sum. 2. c. 4.*): the common maxim of philosophers is "from nothing, nothing comes to be." Therefore some among them — among whom Marcus Varro is listed by Vorrlong (*2. d. 1. a. 2. concl. 3.*) — thought that God produced all things from his own substance. Some, such as Anaxagoras, posited an eternal chaos in which all things were mingled and confused, or, as the Philosopher says, anything was in anything. And from this, perpetual generations were said to separate and segregate them. Others, such as Democritus, suspected that all things were made from atoms and were moved from eternity confusedly and without order, coming to be and being generated by chance. Nor were there lacking those who thought that matter was unproduced and ungenerated, and that all things were produced and generated from it — that Aristotle held this view, Vorrlong testifies (*ibid.*). So before Aristotle, the maxim "from nothing, nothing comes to be" was received by all philosophers, and did not originate with Aristotle. Whether it was rejected or received by him as true or false is disputed by Ferchius (*cit.*). But so that the truth of this may be clearly apparent:

Second Note: There exists a controversy among those same philosophers about the production of natural forms. For form, according to Plato — who calls the same Plato the giver of forms — emanates from an extrinsic source or from God. Others, like Anaxagoras, thought that all forms pre-existed, and the natural agent only separates and segregates them from one another. Aristotle, however, and with him all subsequent philosophers, teach that natural forms are educed from the potency of matter — that is, they depend in being and in becoming upon matter. Hence the same Philosopher (*1. Phys. T. 82.*), in defining matter, says: "Matter is the subject from which all natural composites are generated, and into which all corruptibles are ultimately resolved"; and matter is commonly said to be ingenerable and incorruptible, because it always persists through every generation and corruption as their common subject. The same he writes plainly (*ibid. T. 60.*): "all things come to be from a subject, and this comes from this." And (*2. Phys. T. 28.*) and (*5. Met. 2.*): "Matter is that from which something comes to be." And (*5. Phys. T. 15.*): a common subject is presupposed for

something to come to be, whether substantial or accidental. The same is read (7. *Met.* 8.) and (11.) and (12. *ibid.* c. 12.).

Third Note: Although the question still remains sub judice as to the mind of the Philosopher — whether he admitted (the first mover excepted) that all things are created, or not, as is evident from Scotus (1. d. 8. q. 5.) and (*Quol.* 7.) — and likewise whether the first cause acts ad extra freely or necessarily in the school of the same Philosopher — our Doctor (*now cit.*) asserts that Aristotle held that God acts naturally and necessarily ad extra, and that he created the world from eternity, as one may see (7. 8. *Phys.*). But the Catholic faith teaches us both that the world was created by God in time, and that he operates freely ad extra — as I showed at length in the Treatise on creation (q. 19.). Moreover, among all philosophers and theologians it is certain that creation and generation differ from one another — most of all in that creation is the production or making of a thing from nothing, that is, with no presupposed subject and no pre-existing matter (2. d. 1. q. 5. *infra T.*). In this way an angel is said to be created from nothing. Generation, however, is the production or mutation from non-being to being, with a subject presupposed and pre-existing — which is matter.

Fourth Note, from St. Anselm as cited by Vorrlong (*ibid.*): something can be said to come to be from nothing in three ways. First, materially — that is, nothing is the matter of the making of some thing; and this is impossible, since the matter from which something comes to be is a real being, which is opposed to nothing as affirmation is to negation. Second, causally — that is, nothing is the cause of something; which is likewise impossible, since every cause per se exerting influence upon a real effect is a true, real, positive being, which is opposed to nothing. Third, ordinally — which is to say that after nothing something comes to be; or rather, something comes to be from nothing as from a terminus a quo — just as I asserted above that a composite comes to be from privation as from a terminus a quo. This sense is embraced by theologians who admit the creation of the world in time, freely by God. And according to Aristotle, even when conceding creation from eternity without novelty of being, as Baconius notes (2. d. 1.) — since Aristotle holds that God acts naturally and necessarily ad extra, as I forewarned from Scotus in the second note cited.

Assertion. Aristotle did not reject the proposition "from nothing, nothing comes to be" as false. The Doctor (2. d. 1. q. 2.) does not dissent. I prove it first from Aristotle himself, who at (1. *Phys.* c. 1.) intends to discuss the first physical principles and is wholly occupied with searching for them and determining them in that book, which at (q. 6. T. 42.) he defines; then at (c. 6. T. 56.) adds that they number three; and then at the end of that book at (T. 82.) concludes that matter is the primary subject from which all natural forms are educed.

Therefore throughout that entire book he does not reprobate the aforementioned proposition. Secondly: the same Philosopher does not reject the other two propositions of the eminent philosophers touched upon at the

beginning of this article — namely, that principles are contraries, and that the composite properly comes to be. Nor does there appear any text in which it is refuted by him. For even if at (*T. 33.*) he cites it as the doctrine of Anaxagoras and others, he does not reprove it as a bad assertion, but only in that those philosophers abolished all substantial generation by placing the confusion of things and their segregation, and by holding that all forms pre-exist in matter and that anything is in anything — as is clear to anyone reading the passage cited and (*T. 74.*) and (*1. de gen. T. 8–12.*) and elsewhere frequently. Hence the Stagirite had premised at (*T. 21. c. 2. of the first Phys.*): "one is in potency and the other in act." Then he adds (*T. 78.*): "the other is, because it is in act and potency"; and finally (*12. Met. T. 44.*) he concludes that from an agent nothing comes forth except to extract what is in potency to act. Therefore it seems he does not receive it as a bad principle, but as badly understood and applied; nor does he cite it as his own, but as something already sung by others before him, as is clear (*ibid. T. cit.*) and (*34.*) and (*11. Met. sum. 2. c. 4.*). In this way he sometimes, to demonstrate something beyond demonstration, cites the authorities of ancient philosophers to show that the doctrine he defends is neither new nor devised by himself, but invented and corroborated by others. I noted this (*1. 5. Log. q. 4. a. 11.*).

Thirdly: the doctrines and assertions of the Ancients that displease Aristotle as false and absurd he explicitly and strenuously explodes and pursues everywhere and convicts — as is clear from (*c. 2.*) nearly to (*c. 9.*), where he convicts both those who posited one principle whether mobile or immovable, and those who posited many whether finite or infinite, and those who posited only two, and those who could not distinguish as he does (*T. 74.*): and not only does he solidly and acutely reject them, but sharply and unhesitatingly convicts them of error and ignorance, as is clear (*c. 8. T. 71. 74. 78.*). But at no passage of his book, where it is the proper place to inquire into the truth of that assertion, nor elsewhere, does he absolutely repel the aforementioned doctrine except as badly taken. And (*8. Met. 4.*) he refers back to what he taught in the Physics about the difference that exists between things that come to be simply and not simply.

Fourthly: the same author opens and expresses at length and accurately the ways in which natural things are generated, beginning from (*T. 43.*) of the first Physics to (*T. 48.*), and continues through (*cc. 7, 8, and 9.*). And what the earlier philosophers erred in, he clearly demonstrates there. In these matters, to uproot the errors of the ancients and establish his own doctrine, he admirably and ingeniously provides a twofold manner in which from non-being being comes to be. One is written at (*T. 75.*): "from non-being per accidens — that is, from privation as terminus a quo — something comes to be," and in this he differs from earlier philosophers who affirmed that everything comes to be from being, or from what is. But from non-being simply — which is nothing, or the negation of being — nothing comes to be; and in this he agrees with the ancient philosophers who affirmed that from nothing, nothing comes to be. I cite the

words of the text: "We too say that nothing comes to be simply from what is not; yet something does come to be in a way from what is not — namely, from what is not as a qualification. For it comes to be from privation, which is per se non-being, not from what is inherent in it." The other is found at (*T. 78.*) and more expressly (*12. Met. c. 2. T. 8.*): "Since there is a twofold knowing, everything is changed from a being in potency to a being in act — as from a potentially white thing to an actually white thing; and in the same manner with augmentation and diminution." Therefore not only per accidens does it happen that something comes to be from non-being, but also all things come to be from being — but from being in potency, and from non-being in act. The same distinction is adduced by Aristotle (*4. Met. c. 5. T. 20.*) — to show how those who philosophized about this have reasoned: "To those, therefore, who think on this basis, we shall say that in one way they speak truly and in another they are ignorant. For being is said in two ways. Therefore in some way it is possible for something to come to be from non-being, and in another way it is not. And the same being and non-being can be simultaneously — but not in the same respect: for in potency it is possible for contraries to simultaneously be the same thing, but not in act."

From these it is manifest what Aristotle thinks — in what he agrees and in what he disagrees with the Ancients. He receives the proposition "from nothing, nothing comes to be" by taking nothing simply and per se and insofar as it designates non-being in potency and in act. But he denies it if nothing is taken per accidens and in potency — for he holds that from non-being, that is, from the privation of being or from privation of form as terminus a quo, form comes to be; and from non-being in act but being in potency, something comes to be — as from matter, in whose potency and not in act form is, form can come to be. Therefore, in all his physical works he everywhere preaches that in all physical works a subject or matter must pre-exist, and he commends those who introduced this third principle — privation — and reproves those who did not distinguish privation from matter as another principle, as is clear (*1. Phys. T. 79–80.*).

Fifthly: art imitates nature (*2. Phys. T. 22.*) in many respects, as can be seen (*1. Phys. T. 69.*) and (*2. ibid. T. 86.*) — most of all in this: that if nature always presupposes a subject from which it acts and from whose potency it educes natural forms, so art requires pre-existing matter from which it educes artificial forms. And therefore neither nature nor art makes anything from nothing. Although at (*ibid. T. 24–25.*) certain arts are said to make their own matter, this is not to be taken absolutely — since it is most clear as light that no art does anything without pre-existing matter — but in a qualified sense: some arts prepare and dispose their proximate matter, such as pottery with clay and sculpture with marble; others command others, such as the art of navigation, that of joinery, and that of woodcutting. Thus neither nature nor art makes anything from nothing. Again, Aristotle (*1. Caeli c. 9. T. 95.*) thinks another world is not possible because no other matter is available from which the composites

of another world could be made. He also writes that God and the heavens produce all things through light and motion, and that the efficient cause is the first principle from which motion and rest come (*5. Phys. T. 17.*); active potency is transmutative of another insofar as it is another. These things, and others like them, since they require a subject, plainly show that from nothing, nothing comes to be. Averroes agrees in the Proem to (*3. Phys.*) and (*8. ibid. com. 4.*) and (*2. Met. com. 15–16.*); Bonetus (*1. Phys. c. 3.*); Baconius (*2. d. 1.*); and the other Peripatetics both ancient and modern. So that it is surprising why, in a matter so manifest and known in the school of Aristotle, Veglia (*vest. 1.*) so vigilantly labors and sweats to introduce the opposite into Peripatetic philosophy.

Objection I: Ferchius (*vest. 1. c. 1.*) adduces the book of Xenophanes, in which Aristotle cites the proposition "from nothing, nothing comes to be" as wrong, not his own, and alien to the Peripatetic school. And this is also evident from (*1. Phys. T. 33–34.*) and elsewhere not infrequently. Therefore in the school of Aristotle the aforementioned proposition is not to be received.

I respond: apart from the fact that some consider that book to be a work of Aristotle, Aristotle himself in that book speaks not assertively but dubiously — as is clear from the particle "perhaps" (*fortasse*) added by the Philosopher himself. Malonius agrees (*2. disp. 2.*), adding that Aristotle there proceeds not asserting but disputing. And if it is granted that he speaks assertively, he is to be expounded as above — namely, that he rejects such a doctrine not absolutely, since he expressly admits it (*1. Phys. T. 75.*) saying: "We too say that nothing at all simply comes to be from what is not." But in the manner the Ancients supposed — that all things exist in act, abolishing all generation and new production of things — anything comes to be from what is in act; while from nothing in act nothing comes to be. This is how the ancient philosophers thought, and it is them, philosophizing in this manner, that Aristotle refutes. Ferchius (*vest. 1. p. 40. c. 15. n. 46.*) responds that the particle "simply" is not to be connected with non-being but with the verb "to come to be." But this exposition does not accord with the said text, which reads thus: "nothing simply, from what was not, comes to be" — that is, from pure nothing something cannot come to be; for in this way nothing designates the negation of being, and is non-being simply. But from non-being per accidens, or from privation, something can well be produced — especially because if "simply" is joined with the word substance, it only concerns substance simply, while accident is only in a qualified sense; just as generation simply is of substance alone, and in a qualified sense of accident (*4. d. 11. q. 3.*). But that is not what the Philosopher intends when he explicitly shows there that something comes to be from both the privation of substantial and of accidental form. Therefore the Stagirite concedes that from privation something comes to be, but does not admit that from negation something comes to be.

Objection II: Certainly that proposition does not come from Aristotle — for he says several times expressly that it is the principle and origin of grave errors and evident absurdities: but such is the aforementioned proposition "from nothing, nothing comes to be." Therefore, etc. The major is evident. The minor is shown from (*11. Met. c. 2.*): Heraclitus concedes that two contradictories are simultaneously true. And Protagoras admits that "what appears to each person is true." But that these two great inconveniences arose from that doctrine, the Philosopher writes there. And (*4. Met. T. 19.*) the impossible assertion of Anaxagoras and Democritus — that contraries and contradictories are simultaneously — is said to have proceeded from that same false principle. Again, (*1. Phys. T. 33–34.*): the denial of substantial generation, and instead the segregation of things, flowed from that same pernicious source. Moreover, the maxim of Melissus — that all things are one; that whatever is, is eternal; and other falsehoods and absurdities — arise from that same unfortunate root. Therefore the proposition is manifestly alien to the Peripatetic school, false and absurd, to be thoroughly rejected and exploded.

I respond: these and similar things, which Ferchius investigated and assembled with such diligent and studious labor, are easily refuted and dissolved from the principles laid down and fortified in the preceding remarks. For the Philosopher did not reject it but received it as a true axiom (*1. Phys. T. 75.*) and (*1. de gen. T. 12.*); and all the errors, absurdities, and falsehoods of the Ancients flowed from ignorance and unawareness of the second physical principle — namely, privation — as the Stagirite explicitly teaches there: "For from privation, which is per se non-being, something comes to be." And (*T. 81.*), and in the two final chapters of that book, and (*12. Met. T. 8.*): from non-being in act, and from potency that is not objective but subjective, all natural things come to be — as is clear from the definition of matter (*1. Phys. T. 82.*). But this saying, ingeniously devised by Aristotle — true and necessary, newly introduced into the Lyceum — appeared novel and foolish, marvelous and impossible to the Ancients; while it is declared possible, opportune, and supremely necessary to true philosophy by the same Aristotle (*T. 75.*), and is admirably received and commended by subsequent philosophers. From this, therefore, it is clear what the difference is between Aristotle and the ancient philosophers, and in what way the aforementioned saying is to be embraced and in what way to be rejected.

Objection III: The proposition is denied insofar as it is qualified. But the aforementioned proposition is glossed and narrowed in two ways by Aristotle, as is clear from (*T. 73.*) and (*T. 77.*): "From non-being simply, or from non-being per se, which is pure nothing, or the negation of being, nothing comes to be; but from non-being per accidens, or from non-being in a qualified sense, which is privation, something comes to be." Then (*T. 78.*) and (*12. Met. T. 8.*): "From non-being that is neither in act nor in potency, nothing comes to be; but from non-being in act though being in potency, something comes to be." Therefore per se

from nothing, nothing comes to be; but per accidens from nothing, something comes to be.

I deny the major. For many propositions are qualified that are nonetheless not denied — such as (*1. Post. c. 2. T. 5.*): "That because of which each thing is such is itself more so" — which is restricted by three conditions, but not rejected. Similarly, (*2. de gen. T. 56.*): "The same thing remaining the same always does the same" — which holds in a natural and necessary cause, but not in a contingent and free cause. Again, many things are conceded in the divided sense that are denied in the composite sense, as I explained in the Epitome (*l. 3. q. 4. art. 3.*). And so the qualification of Aristotle, far from driving it to falsehood, on the contrary leads us carefully and industriously to the truth of the same.

Objection IV: Aristotle in the cited book on Xenophanes explicitly says that he once held that proposition together with the vulgar philosophers, and that afterward, having considered the matter more maturely and deliberately, he both cast it aside and expelled it from himself. He writes the same against Zeno. Nor does it help to say that from non-being simply, or from negation, nothing indeed comes to be; but from non-being in a qualified sense, or from privation, and from a presupposed subject, something comes to be. For in this way the difficulty is not dissolved but inverted and evaded. For privation is in the subject, and form comes to be not from the subject but in the subject. But this commutation perverts the sense of the Aristotelian text — especially because the same Stagirite in that book against Xenophanes, pursuing the proof of the proposition he had set forth, supports it with the authority of Hesiod, who clearly sets forth that some things were generated from others and some produced from nothing. Veglia makes much of this argument and thinks he convicts those of the opposite view. And I, thinking him to have dozed rather than kept watch, say that this has already been fully answered — since Aristotle there speaks not assertively but dubiously, as the word "perhaps" (*fortasse*) openly appended by him makes clear. He intends deliberately to introduce the doctrine he himself had previously transmitted and brought into his school (*1. Phys.*) and at the other passages cited above: "From non-being per accidens, and from non-being in act but being in potency, something comes to be." But what Ferchius adds — that it comes to be not from privation nor from a pre-existing subject but in a presupposed subject, and from nothing — is plainly contrary to Aristotle throughout, and to the common body of Peripatetics, who hold that form is educed from the potency of matter — which is to be examined below in the question on form. All the more so because the said author (*vest. alleg. p. 55.*) approves that the opposite comes from the opposite. And he himself urges this very point (*ibid. c. 3. n. 4.*) from (*1. Phys. T. 43.*) and (*T. 47.*) and from (*12. Met. T. 6.*).

To the other objection I say it is stated in the opinion of Hesiod — as is clear to anyone reading the text. Nor should Ferchius, who wants Aristotle to have

pronounced that proposition in the sense of the ancient philosophers, object — for I equally say that he stated it in the doctrine of Hesiod. Add: from (*1. Met. c. 4.*) — Hesiod held that chaos was before all things, then the broad earth, then love. And Tataretus rightly writes for the resolution of the whole difficulty: "From nothing, nothing comes to be naturally; but supernaturally, from nothing something comes to be." I add, according to Scotus and other scholastics, that Aristotle conceded creation from eternity — which the aforementioned Ferchius also admits at the conclusion of the vest. cited.

Question II. On Matter.

The first principle of natural things is matter — inasmuch as it is the first and common subject of their forms and privations (*1. Phys. T. 82.*), presupposed for everything natural as the foundation of nature (*1. Met. T. 17.*), as Augustine indicates (*1. de Gen. ad lit. c. 15.*) and (*l. 8. c. 20.*), and Scotus (*Quol. 10. § de secundo ante S.*) and (*3. dist. 13. q. 4. L.*) and (*dist. 22. § Ad 1. F.*) and (*4. d. 11. q. 3.*).

Therefore, being about to treat of the individual natural principles, we not unreasonably begin with matter, intending to pursue the others afterward with care and in order.

Article I. Whether Matter Exists.

Certain individuals — whose name the Doctor suppresses while mentioning them in both works (*2. d. 12. q. 1.*), thinking that everything generable and corruptible is simple — deny matter; and although thoroughly routed and nearly convicted by the Doctor there, they are still defended by Gomez as cited by Arriaga (*disp. 2. sect. 1.*) and by some others proscribed by the Parliament of Paris, as Camerarius testifies (*q. 1. part 2.*), utterly removing matter. But the common body of ancient and modern philosophers openly and strenuously maintains that matter exists — both in (*1. Phys.*), in (*1. Met.*), and elsewhere throughout.

First Note: Matter has many epithets, which can be comprehended in a list of twelve — six improper, six proper. First it is metaphorically called mother (*1. Phys. T. 81.*) — because from the potency of matter, as from its womb, all natural and corporeal forms are drawn out by the natural agent. Second, female (*ibid.*) — because, receiving forms from the natural agent, it partially concurs in generating the composite, just as a woman concurs with a man in begetting offspring. Third, ugly (*ibid.*) — because it lacks the perfection of form, which is called beautiful and comely. Hence in Genesis I, under the name of earth formless and void, matter is not incongruously named, as Vorrlong (*2. dist. 12. art. 1.*) notes before others. And it is said to resemble the moon. Fourth, by the Egyptians it is called the first law of life because it is the lowest being. Because of this, Augustine (*12. Conf. c. 31.*) calls it near-nothing. Fifth, silva ("wood" or "forest") by the same Augustine (*l. de natura boni c. 18.*) — because just as in a forest the artificial forms are contained in potency, so natural forms are said to

be contained in the potency of matter from which they are educed (*1. Phys. T. 69.*). Sixth, being in potency (*12. Met. T. 22.*) — because it is in receptive potency for all forms. The other six proper names of matter are recited by Avicenna (*1. sufficientia*). The first is the familiar name among philosophers, namely matter — so called because all material things are made from it. The second is mass (*massa*) — because from it, distributed into various portions, various composites are generated (*1. Phys. T. 65.*). The third is origin (*origo*) — because it is the root and foundation of the generation of all natural things, as I warned at the very beginning of this question from Aristotle. The fourth is element (*12. Met. c. 4.*) — because from it all natural things are composed, and into it they are ultimately resolved. The fifth is hyle, from Aristotle (*1. Phys. T. 56.*) and Augustine (*l. 20. contra Faustum c. 14.*) — because it receives forms and desires them (*1. Phys. T. 81.*). The sixth is subject (*subiectum*) — because in it all forms are subjected (*ibid. T. 82.*).

Second Note: Matter is taken in many ways. First, for the individual difference, which the Philosopher seems to touch at (*1. Caeli T. 92.*): "When I say heaven, I say form; when I say this heaven, I say matter." And Scotus expressly transmits (*Quol. 2. Met.*) and (*3. d. 12. q. un. F.*). Second, for the subject of mobility, of which the same Philosopher makes mention (*8. Met. T. 12.*): "perhaps some things do not have matter, or not such matter, but only that which is mobile according to place." Third, for any subject of a material accident, especially of quantity — whether it be immobile, like the empyrean heaven, or mobile, like the other heavens. The Parisians (*1. Phys. q. 4. fol. 22.*) cite this acceptation of matter from Avicembron (*l. fontisvita.*). Fourth, for the coarseness or thickness of something — in which sense a man of dull intellect is called material. Vorrlong (*cit.*) mentions this. Fifth, for the receptive subject of substantial forms — and when speaking of matter thus taken, with Aristotle, philosophers speak in the present context, especially the Doctor (*3. d. 22. q. un. B.*) and (*Quol. 2.*) — from whose potency form is educed, and from which, together with form, the composite comes to be.

Third Note: There are many divisions of matter. The first is into matter *ex qua*, *in qua*, and *circa quam*. This division can be taken in terms of various relations and respects. For if matter is taken insofar as from it the agent educes or introduces form, it remaining, it is truly called matter in the defined sense (*1. Phys. T. 82.*) and (*5. Met. T. 2. 4.*). Matter *in qua* is called the subject of inherence in which a substantial or accidental form is received — thus the intellect is the matter in which knowledge inheres. Matter *circa quam* is the subject about which knowledge is occupied. The second division is into transient and remaining matter, on which the Doctor (*1. d. 2. q. 7. § Ad 1. arg. principale. S.*). Remaining matter is properly matter, as is established from its definition: "Matter is that from which something comes to be, when it is inherent in it" (*2. Phys. T. 28. 2.*). Transient matter is not truly so, but rather appears to assume the character of a *terminus a quo* — as when from the opposite the opposite comes

to be, as fire from air and water from fire. This is called by some the matter of alteration. The third is into matter that is not necessary for the constitution of the thing — such as the matter of syllables is said to be wax, since syllables are made from it, even though both wax and syllables can exist separately from one another — and into that which is indeed necessary for the thing but is not of its essence, as a semicircle is not an essential but an integral part of a circle. The fourth is into remote and proximate matter. Remote matter is that from which a thing is mediately made — as a circle is made from bronze. Proximate matter is that from which a thing is immediately made — thus from a semicircle, as from proximate matter, a circle is made, as Scotus testifies (3. d. 22. q. un.). The fifth is into metaphysical and physical matter. Metaphysical matter is genus; physical matter is the subject of forms, of which we treat in the present context. The sixth is into first and second matter — the former defined (1. Phys. T. 82.), the latter called whatever else is prepared and disposed to receive a form.

Assertion. Matter exists. So Scotus (*loc. cit.*). It is proved first: the natural principles are contraries, as proved in (q. 1. of this book art. 4.); but contraries require one common subject in which they may exercise their contrariety (1. Phys. T. 16. 68.) and (T. 70.). This is most true of properly so-called contraries, which mutually expel one another from the same subject. Therefore matter must be conceded. Secondly: a natural agent always acts from some presupposed subject — hence the maxim "naturally from nothing nothing comes to be" was established by Aristotle and approved by him (*ibid.* T. 75.). But that from which something is made by a natural agent is matter, as is evident (*ibid.* T. 65. 82.). Thirdly: there is substantial transmutation from one form to another when there is perennial generation and perpetual corruption — of both simple and composite things, of both living and non-living; and such transmutation requires a subject, which is matter. Fourthly: a composite substance consists of two things, one of which is related after the manner of potency — which is matter — and another after the manner of act — which is form. Hence (2. Anima T. 2.) substance is divided into matter, form, and composite. Likewise the composite is caused by matter and form as by two intrinsic causes (7. Met. sum. 2. c. 1. T. 7.). Again: just as art requires matter for making its artifacts, so nature presupposes matter for carrying out its natural works (1. Phys. T. 69.) and (1. 2. T. 11.). Moreover: if nothing of a living man were to remain after his death, the holy Church would neither concede nor enjoin the veneration of the relics of the saints; nor would the body of Christ the Lord during the three days when it lay in the sepulcher have been worthy of any cult — since nothing would have been Christ's own, neither soul (which descended to hell) nor matter, on the supposition that matter does not exist. Augustine confesses this truth (12. Conf. c. 32.) and (7. Super Gen. ad lit. c. 6.).

Arriaga (n. 3.) adds that these arguments do not convince Gomez, who thinks differently about natural things than philosophers generally do and than the aforementioned arguments conclude. For Gomez admits that after the death of

a man and of any animate being some subject remains, which he thinks is not prime matter but something composed from the four elements united and mingled with one another, and holds that the elements are simple and alien from all composition.

But if Gomez thought this way — as Arriaga reports — he would unwillingly be conceding prime matter, since as Arriaga himself notes at the beginning of (*sect. 1.*), by prime matter is commonly understood the common subject of substantial forms. But that compound from four elements devised by Gomez is just such a common subject of forms — especially of souls — which persists after the separation of rational souls. Thus through Arriaga's explanation, Gomez would not dissent from the true and common doctrine. Nevertheless Arriaga concedes (*ibid. n. 3.*) that Gomez utterly disagrees with it. And in our school, the body deprived of soul is not a simple substance but one composed of matter and form, for whose composition the union and mingling of the elements is prerequisite. Moreover, the question of whether matter exists would be converted into the question of what matter is. For in the present we investigate whether matter exists. To respond that matter consists of four elements is not to satisfy the question posed. For as will be evident below, Empedocles and other ancients — joined by some moderns — hold that prime matter is the four elements. To hold this opinion is not to deny prime matter, but to disagree with the question of what prime matter is. Since, therefore, we here do not inquire what matter is, it consequently and evidently follows that neither Gomez nor Arriaga in his view satisfies the question proposed and the arguments set forth. All the more so because if a natural agent can create something, as Arriaga responds together with Gomez, then no subject of forms is required — whether composed from elements or from other things; and it can also annihilate something: and all that Arriaga assembles against Gomez collapses, since it presupposes some subject — as can be seen from him — and when that is supposed, his arguments are strengthened. But that a natural agent can create contradicts the decree of the Ancients (*11. Met. c. 4. sum. 2.*) and conflicts with the truth — as I shall show elsewhere.

Objection I: If matter existed, it would be in one of the ten predicaments — for since it would not be an infinite being, which is God alone, it would be a finite being, which, from what was said in the Logic (*l. 3. q. 4.*) and from what will be said in the Metaphysics (*l. 2. q. 1.*), is distributed into ten supreme genera. But matter does not reside in any of them — since from (*7. Met. T. 8.*), it is "not what, nor how much, nor any of those by which being is determined." Therefore matter is not to be conceded.

I concede the major and deny the minor. To the testimony of Aristotle I say that it carries its own solution, when he says "not any of those by which being is determined" — where he signifies that matter is not an act actuating and

distinguishing, such as form is, but is indifferent and indeterminate to receive any form whatsoever.

Objection further: Matter is predicated of nothing essentially, but only denominatively — from the same Aristotle (*ibid.* T. 25.). Therefore since matter is nothing of what things are, it is altogether nothing.

I concede the antecedent and deny the consequence. For if matter is predicated denominatively, it is something — since nothing does not denominate something, as the Doctor rightly infers (*cit.* § *Ad arg. ante I.*).

Objection II: If matter existed, it would be either a being in act or a being in potency — since being is sufficiently divided into being in act and being in potency (11. *Met. sum.* 2. c. 4.). But matter is neither — not a being in act nor a being in potency, as is clear from (5. *Phys. c.* 2. T. 8.): "what is moved is, but what is generated is not." But matter is not what is moved — for that is a natural body; nor is it what is generated — since properly generation belongs to the composite alone (7. *Met.* T. 26.).

I concede the major and deny the minor. To its proof I say that the subject of motion is indeed the natural composite, while the subject of generation is matter, which is the subject of substantial forms. And so it is clear that the mobile is in potency to an accidental form, and the generable to a substantial form.

Article II. What Matter Is.

Although the vulgar crowd and the whole body of philosophers acknowledged matter from which all natural things are generated — for they established that maxim "from nothing, nothing comes to be" — yet what matter is, its nature and quiddity, was hidden from them. For the sake of distinction and clarity I divide their positions into the following doubts.

Doubt I. What the Vulgar Thought About Prime Matter.

An ancient and widespread opinion it was, as Aristotle testifies (1. *Met. c.* 7. T. 14.), that earth is the matter of all things from which all natural things are composed; the same Philosopher reports (*ibid.*) that Hesiod held this, and Pherecydes subscribes — as Theodoret (*l. de materia*) narrates. But that no later philosopher embraced it, Aristotle himself asserts and proves in that place. We agree with them.

We assert: Earth is not prime matter. The reason is that earth is very dense and dry, and takes on other qualities that do not render it apt for easily receiving figures and forms. Furthermore, earth is composed of matter and form, as will be shown below for the other elements as well. Therefore earth is not to be considered prime matter.

Objection I: In Genesis I, where the Vulgate reads "but the earth was formless and void," St. Augustine (*1. de Gen. ad lit. cc. 1, 2, 14, 15.*) and (*l. 2. of the same work c. 11.*) translates it as "the earth was invisible and unorganized," and affirms that the sacred text there intimated prime matter under the name of earth. Not incongruously, therefore, is earth named prime matter.

I respond: although the divine Chronicler under "earth" intended to signify prime matter — and also water — to the uneducated people, as Augustine notes (*l. 1. cit. c. 15.*) — because these two elements are more tractable to the hands of those who work and make something — yet in truth neither earth nor water is prime matter, since they are composed of matter and form. Just as the same Moses, by heaven, indicated every spiritual creature (even though heaven is a physical composite), and by earth every corporeal creature — as the same Augustine interprets (*l. 1. cit. c. 1.*). This the Lateran Council sanctions: "God created both creatures — the celestial and the mundane" (*c. Firmiter de summa Trinitate et fide Catholica*).

Objection II: All things come from earth and return to earth — Genesis III: "In the sweat of your face you shall eat bread, until you return to the earth from which you were taken." Moreover, earth is at the center of the universe as the fitting receptacle of all forms. Furthermore, from it living things are generated, nourished, and fostered. Therefore it is now called Vesta, now Ceres, now the common mother.

I respond: although man and other terrestrial animals are resolved into earth, that resolution is not the ultimate one — there still remains a further resolution into prime matter, to be examined in the book on generation (*q. 3. a. 2.*). Earth is situated in the middle of the world because it is the center of the world itself; it is called mother not on account of receiving forms, but because of the nourishment it furnishes to living terrestrial things — just as water can be called the mother of fish, and air of birds.

Doubt II. What Thales of Miletus Thought About Prime Matter.

Thales of Miletus, the inventor and founder of natural philosophy (*1. Met. c. 3. and c. 7. T. 14.*), posited water as the first material principle of natural things — as Augustine (*8. Civ. c. 2.*) and Vives (*ibid. in com.*) report, the latter citing in favor of this opinion Cicero, Eusebius, and others. The same is signified by Orpheus, Musaeus, and the other ancient poets and theologians, who call Oceanus and Tethys the parents of all things; and indeed the sacred text of Genesis I seems to indicate it: "The Spirit of the Lord was borne over the waters" — where Augustine (*1. de Gen. ad lit. c. 18.*) says that in the Syriac idiom the reading is "resounded"; others render it "brooded over." The same Doctor (*cit. c. 5.*) explains it with this simile: "Just as eggs are warmed by birds, where the warmth of the mother's body also contributes in some way to the formation of the chicks through a certain affection of love in its kind." It is also suggested by (*Matt. 23.*):

"as a hen gathers her chicks" — in the same way God brooded over the water as the first matter, so that from it he might educe all the forms of things he willed. And this does not displease the same Augustine (*ibid.*), who under the name of water calls the whole matter — the reason he gives being that from a humid nature we see all things on earth take shape and grow through various forms. The same holy man intimates the same thing in the unfinished work on Genesis (*c. 4.*). And before this, Egypt figured it in the idol of Serapis, which represented water. That Thales descended to Egypt to study, and that the Egyptians were taught by the Hebrews, I reported (*l. 1. q. 1. a. 1.*). It therefore does not seem improbable that that opinion about prime matter under the name of water was borrowed from the sacred codex.

Nor is it valid what Fonseca adds (*1. Met. c. 7. q. 2. sect. 2.*): that in Holy Scripture, water is not taken to mean prime matter but the familiar element of water; nor that the Egyptians under the image of Serapis adumbrated prime matter, but rather water, which is numbered among the elements — on account of the Nile, which floods and irrigates their entire territory. For St. Augustine at the passage cited clearly interprets that passage of Genesis as referring to prime matter, which he himself calls formless, unorganized, and invisible matter, from which the world — consisting principally of two great parts, namely heaven and earth — was fashioned with the elements arranged and form received. And there he adds that matter preceded form not in time but in origin or nature. Thus the exposition of the sacred text — whether by the name of earth or of water prime matter is understood — is congruous. Hence (*c. 4. of the unfinished work cit.*) he subjoins: "For this reason, more fittingly would matter be named by the name of water when it was shown to be subject to the work of the artificer, because of the mobility and conversion into any nascent body, than by the name of air, in which only mobility could be observed." All the more so since in Holy Scripture, under names other than earth and water, prime matter — which was undoubtedly created by God — is not indicated. Yet these considerations notwithstanding:

We assert: Water is not prime matter. Aristotle (*ibid.*) and Scotus (*ibid.*) hold this. It is proved first: water requires and presupposes matter as its part — for it is one of the four common elements, which are simple bodies composed of matter and form, as will be proved below. Secondly: water is transmutable, like the other elements, one of which is transmuted into another. From air, fire is generated, and from water, earth; but matter is ingenerable and incorruptible, since it is the common subject of all transmutations. Therefore water is not prime matter.

Objection I: St. Augustine (*1. de Gen. ad lit. c. 5.*) and (*1. de Gen. contra Manich. c. 7.*) seems not to reprove but to approve the opinion of those who understand formless matter under the name of water. Therefore the opinion of Thales, who decreed water to be the first material principle of natural things, is plausible.

I respond: Augustine indeed affirms that under the name of water the first matter can be signified in Sacred Scripture — because since it is certain that prime matter was created by God, and the sacred text expressly does not mention its creation, the holy Doctor writes that it can fittingly be designated by water. Yet in truth it is not prime matter, but an element composed of matter and form.

Objection II: From (*1. Met. c. 3.*): water is humid; but the nourishment of all things is humid; even the warm is nourished by the humid; animals live by the humid and perish when it is consumed; and indeed all seeds have a humid nature. Therefore since water is the principle of humid things, it is not unfittingly asserted that it is the first material principle.

I respond: these and similar motives that can be adduced for introducing water as the material principle of natural things only prove that water is necessary for nourishing all mixed things, and that it is in some way their sustenance and quasi-fodder — so that it should be called second matter rather than first. Looking toward this, perhaps, the Church sings at Vespers on the feria: "Great is God's power, / Who made the race that rose from the waters, / Part by releasing it into the deep, / Part by lifting it into the air."

Doubt III. Whether Prime Matter Is Air.

Anaximander, the successor in the school of Thales but not the defender of his opinion, posited as the material principle of things an infinite element, without specifying which element it might be. His hearer Anaximenes, third in the Ionian sect, expressly affirms it to be air — as Aristotle (*1. Phys. c. 6. T. 54.*) and (*1. Met. c. 7.*), Augustine (*8. Civ. c. 2.*), Cicero (*1. de natura Deorum*), and others cited by Vives in his commentary on the said Augustine (*alleg.*) report. By air, however, in the book of Genesis prime matter is not designated — although the same Augustine (*in the unfinished work de Gen. ad lit. c. 4.*) narrates that some understood the element of air under the name of spirit. Thus the royal prophet names air in this way (*Ps. 118.*): "I opened my mouth and drew in the spirit." Why air is not so fittingly held to be matter as earth and water — the reason Augustine (*just mentioned*) touches upon: that air or fire has rather the power of acting than of suffering, which is adapted to matter.

We assert: Air is not prime matter. So Scotus with Aristotle (*ibid.*). It is urged by the common middle argument: air is one of the four elements, as philosophers commonly teach and St. Augustine (*cit.*). But the individual elements consist of matter and form, as is clear since they are natural bodies composed from the said matter and form. Therefore prime matter is not air. Again: air excels water and earth; and what is superior is more active than what is inferior. For this reason fire, since it is more eminent than the rest, is most active; but prime matter is said to be the lowest being and passive. Therefore air is not to be thought prime matter.

Objection: It is the proper characteristic of matter to receive all forms, according to the common agreement of philosophers. But air more easily than water receives external and foreign impressions of heat, cold, smell, and the like. Therefore air should be considered prime matter.

Confirmation I: Air is warm and humid, in both of which animal life consists and is preserved.

Confirmation II: Air, as has been said, is called spirit; and in seed there are spirits; and therefore perhaps seed is called divine by Galen. All the more so, demons who are spirits are called aerial powers and aerial animals, as Augustine indicates (3. *de Gen. ad lit. c. 10.*) and (8. *Civ. T. 15.*).

I respond: the major holds of substantial forms, not of accidental ones — of the kind that air receives, and which are adduced to strengthen the minor. To Confirmation I: I say that this only proves that animals, especially terrestrial ones, need air for living and breathing — which I freely admit. To Confirmation II: I say air is called spirit because of its tenuousness and subtlety; whence perhaps demons are said to be aerial — either because they dwell in the air, as is read in Augustine (*ibid.*).

Doubt IV. Whether Fire Is Prime Matter.

Aristotle (1. *Phys. c. 2. T. 6.*) mentions those who hold that fire is the first principle, though he refrains from naming them there; but (1. *Met. c. 3.*) he explicitly names them as Hippasus of Metapontum and Heraclitus of Ephesus, and he ranks their opinion (*ibid. c. 7. T. 13.*) above the reasoning of the others.

We assert: Fire cannot be prime matter. Aristotle and Scotus (*ibid.*) hold this. Beyond the common middle argument, one can urge: fire is superior to air and the other sublunary things, as Augustine testifies (2. *de gen. ad lit. c. 3.*). But prime matter is the lowest of all things; for this reason it is said to be like dregs and like nothing. Again: fire is most active, while matter is passive; fire is ranked before the other elements in nobility; but matter is subjected to all things. Furthermore, fire by means of moderate heat gathers homogeneous things together; but matter without distinction receives all forms on account of the universal appetite it has for them. Finally, since dryness and heat are adapted to fire, and when dryness presses and heat burns, animate things nearly perish — it seems inept to hold fire to be the constitutive principle of those things of which it is destructive.

Objection: Fire is the thinnest and most subtle thing. Hence into its sphere it does not suffer external impressions to enter; the other elements, however, are coarse and impure. It pervades and penetrates all things and is divided into the minutest parts, as the Philosopher notes (*ibid. T. 13.*). I add that fire is the fount of heat; and that in warmth chiefly life consists — no one fails to see this. It therefore seems plausible that fire is the first principle of physical things.

I respond: this instance only shows the excellence and eminence of fire above the other elements — but it does not prove that fire itself is the first matter and principle of things.

Doubt V. Whether Prime Matter Is Something Intermediate Between the Elements.

Some make prime matter something intermediate between fire and air, which Aristotle (*1. Phys. c. 4. T. 32.*) mentions. Others make it something intermediate between fire and water — as the same Philosopher testifies (*1. Met. c. 7. T. 14.*). And both opinions the same Stagirite reports (*2. de gen. c. 5. T. 32.*), counting it more probable than the preceding ones (*1. Phys. c. 6. T. 54.*). The reason why no philosopher placed anything interposed between water and earth is perhaps that earth is coarse and dense and not apt for receiving any forms whatsoever.

We assert: No intermediate thing — whether between fire and air, or between air and water — is to be posited as the first principle of natural things. The Doctor, Aristotle, and Scotus presuppose this (*loc. cit.*). It is proved first: prime matter is indeterminate and indifferent to receiving any forms whatsoever, since it is the common subject and universal receptacle of forms. Therefore it is not aptly restricted to being something intermediate between fire and air, or between air and water — since it must embrace and encompass all forms of every natural thing. Secondly: such an intermediate between the aforementioned things devised by the aforementioned philosophers is either composite or not. If the first, then it is not matter — which is presupposed by nearly all as a part of the composite. If the second, it no more ought to mediate between those elements than between others. For not only what pertains to fire, air, and water participates matter, but also what pertains to earth and all the other natural composites. Moreover, it is not explained what that intercepted intermediate is, nor is it proved, nor is anything worth knowing adduced to establish it. And to say that it is infinite, as Anaximander holds, is of no help — since Aristotle in many places convinces that an infinite being in act is not given (*3. Phys. c. 5., 1. de gen. c. 3., l. 2. c. 1. and following.*).

Objection: Prime matter is not assigned to sensible things, nor is it affected by contraries, since it is the foundation of nature immune from them and subject to all transmutations. Therefore matter appears to be that intermediate between the aforementioned elements.

I grant the antecedent and deny the consequence, for the reasons adduced in the proposed assertion — since by those words the perfect nature of matter is not designated, nor are the other things that pertain to its integrity and to a perfect knowledge of it conveyed.

Doubt VI. Whether All Things Are One Material Principle.

Those who introduced one principle are, as Aristotle testifies (*1. Phys. c. 1. and Met. c. 3.*), bipartite. For some — like Melissus and Parmenides, speaking unnaturally — thought that one principle to be immovable. Since nature is a principle of motion (*2. Phys. T. 3.*), and such a one principle is devoid of motion, Aristotle rightly considers them unnatural — as denying natural principles. Others, whom I recalled in the preceding doubts, posit that one principle as mobile — such as water, or air, or fire, or something interposed — of whom enough has been said above. Now it is worth briefly pursuing those who make it immovable, or who are internally inconsistent. For Melissus thinks it infinite, while Parmenides thinks it finite. Both, however, assert that all things are one — and these Aristotle sharply refutes and clearly convicts (*cit.*), proceeding metaphysically, as Alexander and others note there before all.

We assert: All things are not one principle. So Aristotle (*ibid.*) and the Doctor presupposes (*ibid.*). It is proved first: to say all things are one principle involves a contradiction in terms — for if it is a principle, then certainly there is something principiated. For principle and principiated are correlatives, just as cause and effect; but principle and principiated cannot be one and the same. For what is from another must necessarily be distinguished from that which is not from another, since the same thing cannot be from itself and dependent upon another, and independent; origin and originated; maker and made; cause and effect. Secondly: being is divided into infinite and finite — the former bounded by no limit, the latter constrained by a term. But to be unbounded and bounded are without doubt not one and the same. Moreover, being is divided into substance and accident: substance is being subsisting per se; accident is being inhering in another. But to be per se subsisting being and to be inhering in another plainly do not coincide. Furthermore, finite being descends to the ten supreme genera, which are clearly established to be distinct from one another. Again: if all things are one, then consequently all things are of the same species; and thus plant, tree, horse, lion, and man would not differ in species — and that these and many similar things are absurd, no one fails to see. Hence Aristotle rightly adds (*1. Phys. T. 10. 22.*): given one absurdity, many follow. Moreover, if all things are one — either with the unity of continuity, but this cannot be since the continuous is divisible into parts of which one is not another; or with the unity of indivisibility, but this too cannot cohere, since the indivisible is not a quantity, and therefore would not be infinite as Melissus said. To quantity, however, finitude or infinity belongs. Nor can they be one by definition — otherwise the same thing would be simultaneously white and black, good and bad; contraries and contradictories would simultaneously be true and false — which Aristotle shows to be absurd (*4. Met. T. 19.*).

Objection I: On the part of Melissus — whatever is, either is generated or ungenerated; but it is not generated; therefore it is ungenerated. The major is evident — for what is, is either from itself or from another; unproduced or produced. The minor is urged: what is generated is generated either from

another or from nothing; not from another, since it would already be a being before it was, which is repugnant; nor from nothing, since from nothing nothing comes to be. If therefore it is ungenerated, it has no beginning; but what has no beginning has no end; and what is without beginning and end is infinite; but what is infinite does not admit another alongside it. Therefore Melissus concludes there is only one infinite and immovable principle.

Aristotle responds that this argument errs both in form and in matter. In form, because its minor is negative, from which in the first figure no conclusion follows — as observed in the *Epitome* (*l. 3. q. 1. a. 10.*); or, as others say, the inference proceeds from the inferior to the superior negatively — as if someone were to reason: "he is not a man, therefore he is not an animal" — which is censured (*3. Elench. 4.*). In matter it is deficient, arguing from the beginning of time (when it is said: "what has no beginning has no end") to the beginning of magnitude (when it is inferred: "it contains all things and occupies all place, because it is infinite").

Objection II: On the part of Parmenides — cited (*1. Phys. c. 2. 3.*) and (*1. Met. c. 5. before T. 1.*): "Whatever is, besides being, is non-being; but non-being is nothing; therefore whatever is, besides being, is nothing. But being and one are interchangeable; therefore whatever is, besides the one, is nothing; and so there is only one being, and this immovable, since it has nothing by which it might be moved."

I respond: this argument of Parmenides, although in Aristotle's judgment (*1. Phys. T. 23.*) it is not so empty as that of Melissus, is nevertheless captious and sophistical, erring through the fallacy of equivocation. For being and one are said in many ways — as Tataretus notes with Aristotle (*1. Phys. q. 2. scib. 2.*). For if they are taken transcendently, the instance is indeed true but does not conclude what was intended — since the proposal of the aforementioned Parmenides was to prove that there is only one being existing numerically in act, and this immovable — as Toletus notes in the text just cited together with other interpreters.

One might say: if the ancient philosophers, compelled by truth, decree that principles are contraries — as Aristotle testifies (*ibid. c. 5. T. 48.*) — how is it that the aforementioned authors assert there is only one principle, since one and many — these being contraries — do not cohere? One must respond that they thought there to be one principle according to truth and reason, but many principles according to sense and appearance. Thus some of them posited hot and cold, some humid and dry, some even and odd, and others rare and dense. These held that all things are of the same nature and species, and that the difference between them is only accidental. Hence they distinguished the elements in rarity and density and other accidents; and mixed things in terms of the diverse combinations of said elements — and these from those as warm water from hot and cold water. And they held that accident does not deserve the

name of being, nor is to be placed among beings, as Fonseca notes (*1. Met. c. 7. q. 2. sect. 3.*).

Doubt VII. Whether There Are Many Material Principles.

After careful examination and diligent investigation of one-principle positions, their defects and absurdities had been seen and, wishing to avoid them, later philosophers suspected there to be many material principles — some thinking them infinite, others finite (*1. Phys. c. 2. T. 6., 1. de gen. c. 1., 1. Met. c. 4.*). The opinion of the former we treat in the present doubt, and that of the latter in the following one. Among those who posit infinite principles, Leucippus, Democritus, and Anaxagoras are most cited — saying those principles are little bodies, or atoms, indivisible and insectile either mathematically or physically, from whose composition and aggregation (in terms of diverse figure, order, and position) perennial generations come to be, and from their dissipation and segregation perpetual corruptions of things occur. Then some of them, like Democritus, add that all atoms are similar, from which homogeneous things are generated; others, like Anaxagoras, hold those atoms to be dissimilar, from which heterogeneous things are composed. Others add that natural bodies are constituted not only from these as something full, but also from the void or empty. And what is marvelous — they maintain that from these, infinite worlds are composed, that all things are naturally generated and corrupted as those atoms are set in circular motion through infinite spaces, and as they roll about by chance, at times combining into these bodies, at times segregating — and so generations and corruptions of natural things occur. From this they deduce that all things are made by chance, that the universe is governed and ruled fortuitously, and is finally dissolved.

We assert: The material principles of natural things are not infinite, whether they are held to be similar or dissimilar. Aristotle transmits this (*1. Phys. c. 4. T. 35.*), and Scotus does not dissent (*in com. Met. ad T. 15.*). It is proved first: natural things are knowable, for physical science is about them. But the principles of a knowable thing are known — for we consider that we know a thing when we know its principles (*1. Phys. in initio*); and the whole is perspicuous to us when its parts are known to us. But the infinite is unknown, as the Philosopher rightly pursues (*1. Met. c. 2.*). Therefore infinite principles of natural things are not given. Secondly: animate natural things are bounded by a definite limit of their size or smallness (*2. Anima T. 41.*). Therefore they do not consist of infinite principles. For if their principles and parts were infinite, they too would be infinite. And from evident experience it is seen that they are constrained by definite limits of their size or smallness. All the more so, since an infinite being in act is not given and cannot be given — as will be proved in the book on quantity (*q. ult.*). Furthermore, if parts are removed from any natural composite, it diminishes and is finally consumed — a manifest indication that in it there are not actually infinite parts, nor similarly infinite principles. Moreover, it is not

apparent how such indivisible atoms are receptive subjects of divisible and material forms. Nor can a real positive being — such as a natural composite — consist from them and the void. Again: the inconveniences of the earlier philosophers are not avoided. For given such atoms and infinite principles, natural things would still differ accidentally from one another in figure, position, and other accidents — since generations would mean nothing other than alterations and aggregations of things, and corruptions their separations and disaggregations. Finally, it is foolish and absurd that this most firm and beautiful mass of the world was established by chance, and is governed, ruled, and preserved fortuitously. Hence Democritus, laughing at all things and defending these positions, made himself plainly ridiculous to all. And rightly the mark of ignorance and imprudence is tacitly branded upon him (*1. Phys. T. 39.*), and he is refuted (*1. de gen. c. 1.*), and ranked below Empedocles at that passage (*T. 40.*) and (*1. Met. c. 3.*).

Anaxagoras proves his opinion and renders it plausible on the basis of two foundations: the first is "from nothing, nothing comes to be"; the second is that contraries come from contraries. Everything that comes to be, comes to be either from non-being or from being; not from non-being — because from the first foundation received by all, "from nothing, nothing comes to be"; nor from being, since then it would already be a being before it came to be. But what comes to be from being comes from a contrary — as hot from cold and humid from dry — as is clear from the second foundation. But it does not come from a contrary remaining in the generated thing, as is evident. For the cold from which the hot was produced does not persist in the hot, nor the dry in the humid. Therefore it comes from being that was present in it or lay hidden in a contrary. Such being is the infinite aggregate of atoms, commonly called chaos, in which all things were supposed to be mingled, confused, and hidden. I respond: this argument has already been dissolved in (*q. 1. of this book art. 7.*), where according to Aristotle it was established that from non-being simply and per se nothing comes to be — in which sense that assertion "from nothing, nothing comes to be" is understood. But from non-being per accidens and from being in potency, something can well come to be — thus from privation as terminus a quo, form is educed from the potency of matter, and from matter and form the composite comes to be.

Doubt VIII. Whether the Four Elements Are Prime Matter.

Aristotle (*1. Phys. c. 4. T. 40.*) approves the opinion of Empedocles who decrees there to be many and finite principles, but reproves his position of holding those principles to be the four common elements transmutable into one another — as can be seen (*1. Met. c. 7. T. 15.*) and at other places.

We assert: The four elements are not the prime matter of natural things. This is deduced from Scotus (*in com. 1. Met. ad T. 15.*). It is proved first: matter is ingenerable and incorruptible, since it is the common subject of generation and

corruption, as the Doctor explains (*in 1. Rep. d. 5. q. 2.*). But the elements are mutually transmutable. From water, air comes to be; from air, fire; and so of the rest — perennial generations and perpetual corruptions of them occur (*3. Caeli and 2. de gen.*). And this is plainly indicated by their qualities continually fighting and mutually expelling one another from the same subject. But such alterations, generations, and corruptions require the same common subject, which is their common matter. Therefore the four elements cannot be prime matter.

Secondly: principles are contraries (*1. Phys. c. 5. T. 48.*); but contraries must share the same common subject in which they exercise their contrariety — as is clear from their definition. Therefore they require and presuppose a common subject, which is matter, as Aristotle acutely subjoins (*n. cit. c. 7.*). Consequently elements cannot be the matter of natural things. Thirdly: Aristotle argues in the *Metaphysics* (*passage alleg.*): if Empedocles does not admit common matter for the elements, he undoubtedly abolishes alteration — which is the motion of the same subject according to contrary or intermediate qualities (*1. de gen. c. 4. T. 24.*); but that alteration exists is clearer than light; and if alteration is removed, which naturally tends to corruption, corruption too would be removed, and consequently generation — since the corruption of one is the generation of another (*1. de gen. c. 4. T. 17.*). Furthermore, if elements were the matter of natural things, they would be formally in the mixed thing — just as matter formally exists in that of which it is matter — and matter would be of diverse character, just as the elements are of distinct species. Moreover, there would be four prime matters, as there are four elements, and matter would exist without form — since the elements themselves would be matter without form. These and similar things seem very inept and absurd. I add: from the cited passage (*1. Phys. c. 4. T. 32.*), Empedocles agreed with Anaxagoras in positing confused chaos, or the sphere, from which they thought all things came to be — although they differed in some things, as I suggested above and Tataretus explained (*in exp. of the aforementioned c.*). Therefore that chaos rather than the elements that arise from it is prime matter. Finally: in the book on elements I shall show that the elements are composed of matter and form. Therefore the elements themselves cannot be prime matter.

Objection I: Mixed things differ essentially — and of their essence matter is included, as will be proved below. Therefore their matter must be essentially distinct, and this distinction is sought in terms of the four elements. Consequently the elements are the proper matter of all natural things.

I concede the antecedent and deny the consequence, because their essential difference is derived from their forms.

Objection II: Mixed things are generated from elements fighting among themselves, as the common opinion of philosophers holds. Therefore the elements are the matter of all natural things.

I distinguish the antecedent: dispositively — I concede; effectively and principally — I deny. Unless one says that the elements are matter, not indeed prime, but second matter.

Doubt IX. Whether Numbers Are Prime Matter.

So much power and force does custom have in contemplating or doing things that it seems equal to nature — according to that commonplace: "custom is a second nature." Hence the Pythagoreans, accustomed to and exercised in mathematical disciplines, thought that unity or number was prime matter — as Aristotle testifies (*1. Met. c. 5. and T. 19. of the same work and following*). For since in magnitude nothing is prior to unity and number, they consequently thought that all things are composed from unities and that all things are numbers — as if from a subjected matter — perhaps imitating certain people called secret theologians among the Hebrews, Kabbalists, as can be seen in the *Harmonia Mundi* of Francesco Giorgio.

We assert: Numbers in no way can be the matter of natural things. The Doctor holds this with Aristotle (*in the texts just cited*). It is proved first: a corporeal substance is not composed from an accident — otherwise the composite would be a being per accidens. But unity and number are accidents placed in the genus of quantity; yet matter is reduced to the predicament of substance as a part of the physical composite. Therefore numbers are not the matter of physical things. Secondly: substance is prior to accident in nature, time, and definition (*7. Met. c. 1. T. 4.*). But number presupposes things to be numbered — for it is because things pre-exist that they can be numbered. Since, therefore, number follows upon things to be numbered, it cannot be their matter. Thirdly: number is found not only in natural things, which are mobile, but also in others that are immovable. Again: mathematics would not differ from natural philosophy — which conflicts with (*2. Phys. c. 1.*). Moreover, principles are contraries; but numbers undergo no contrariety. Furthermore, it is proper to matter to receive any form whatsoever; but numbers are not capable of receiving any form whatsoever. From these and other things adduced by Aristotle (*c. 7. of the passage just cited*), it is plainly deduced that the Pythagorean opinion is absurd and improbable.

Objection: It is recorded that Plato received much from Pythagoras; and that the same Plato thought well about matter is evident from what he writes in the person of Timaeus. Aristotle also seems to concede this (*1. Phys. T. 80. c. 9.*), and there he only reproves the saying of Plato because Plato himself despised privation and did not distinguish it from matter. Therefore Pythagoras and Plato agree in substance with Aristotle, even if they differ in words, and they adumbrated that matter under unity and number, and under the great and small.

I respond: even if Pythagoras had some knowledge of matter, he does not seem to have fully grasped its nature — since he treated it not physically but mathematically. And the opinion about matter so proposed at the beginning of this article is undoubtedly false. As for Plato: even if much erudition should not be denied to him, he nonetheless does not seem to have fully recognized the essence of matter, since he did not segregate it from privation — as Aristotle charges him (*at the passage just cited.*). And then in the *Timaeus* (*alleg.*) he named the very same matter "this something" — which was not said correctly. For, as Aristotle rightly adds (*2. Anima c. 1.*) and (*7. Met. c. 2.*), "this something" is not matter but the composite.

Doubt X. What Matter Is According to Aristotle and the Truth.

Having dismissed and routed the ancient philosophers, Aristotle sets forth his own opinion in two places — namely (*1. Phys. c. 9. T. 82.*) and (*7. Met. c. 3. T. 8.*). And indeed in the first place he defines matter positively: "Matter is the primary subject of each thing, from which something comes to be, when it is inherent in it, and not according to accident; and if something is corrupted, into this it ultimately passes." In the second place, negatively: "Matter is not what, nor how much, nor what kind, nor any of those by which being is determined." In the same manner God is known both positively and negatively — as the Doctor says (*1. dist. 3. q. 1.*). That this is a privilege of the most perfect and of the most imperfect being, the Seraphic Doctor notes before others (*2. dist. 3. q. 2. art. 1.*). Hence God is said to contain the fullness of all goods and perfections — Exodus XXXIII: "Come, and I will show you all good." And St. Anselm (*in Prosl. c. 2.*) subjoins: "God is that than which nothing greater can be conceived." Both modes of defining are also observed by Porphyry (*Isag. c. de accidente.*): "An accident is that which is present and absent without the corruption of the subject." Then: "An accident is that which is not genus, nor species, nor difference, nor property." Augustine agrees — who at (*12. Conf. c. 3.*), confessing that matter is a certain real positive lowest being, yet expresses it through negations in these words: "Did you not teach me, O Lord, that before you formed and distinguished this formless matter, there was not anything — not color, not figure, not body, not spirit — yet it was not altogether nothing? It was a certain formlessness without any species." And at (*ibid. c. 5.*) he adds of that same matter: "Let human thought strive either to know it while not knowing, or not to know it while knowing."

Assertion. Matter is well described as: "the primary subject of each thing, from which something comes to be, when it is inherent in it, and not according to accident; and if something is corrupted, into this it ultimately passes." This is explained with respect to all its particles before it is proved. "Subject" is placed on account of form, which is in a subject — just as a part is in its co-part and the perfecting in its perfectible. "Primary" is added to distinguish it from second matter, of which in Article I of this question. "Of each" is placed — that is, of

each substantial form. "From which something comes to be" is added — meaning, a composite. "When it is inherent in it" is appended to exclude privation, which withdraws when form arrives — as Scotus interprets (*1. dist. 2. q. 7. § Ad 1. arg. principale. sub S.*) and (*2. d. 12. q. 1. ante § Hic dicit.*). "Not according to accident" is added both because matter is a principle per se, and also because from matter and form something one per se comes to be. Finally: "and if something is corrupted, into this it ultimately passes" is subjoined because matter is the common subject of generation and corruption. From matter, indeed, all natural things are generated, and into it they are ultimately resolved. Therefore it is said to be ingenerable and incorruptible.

The assertion thus explained is urged first: that definition is apt which explains the nature of the thing defined — as stated in the Epitome (*l. 2. q. 7. art. 2.*); but the aforementioned definition of matter is of this kind, as is clearly established from the explanation of each of its words set forth above. Secondly: that definition is deemed suitable for things that are not of a complete specific nature but are parts of a species and incomplete, which consist of a quasi-genus and difference. But the aforementioned definition of matter is of this kind — for matter is a part of the physical composite. Therefore subject serves as a quasi-genus, and the remaining particles hold the place of a difference. Such a definition is therefore legitimate.

Objection I: A definition, according to Scotus (*4. D. 1. q. 2.*), belongs to a real positive, per se, composite, and universal being. But matter is not a real positive, composite being — since (*7. Met. c. 3.*) "matter is not what, nor how much, nor what kind, nor any of those by which being is determined." Therefore the definition of matter is not rightly adapted.

I respond: the major is to be glossed as speaking of definition strictly taken and complete in all its numbers — which in truth cannot apply to matter, since it is a part of the composite. Conceding, however, the major, one can say with Scotus (*cit. § Ad arg. 1. H.*): Aristotle is speaking in the person of the ancient philosophers — as is clear from the course of the text, for he adds these words: "thus it happened to those who attended that matter is the subject; but this is impossible." But Aristotle's manner is not to assert something but to declare it impossible. Or say with the same Doctor (*ibid.*): if Aristotle speaks in his own judgment, the aforementioned instance carries its own solution — for those words "by which being is determined" indicate the nature of matter, which is to be indifferent and indeterminate for receiving any form whatsoever. This is true and no one I have seen dissents from this explanation. And Augustine intimates it (*cit. c. 3.*): "Not altogether nothing; but a certain formlessness without any species."

Objection II: What is absolute is not defined through what is relative — otherwise it would not be absolute but relative, as is clear from the description of each adduced in the Epitome (*l. 1. q. 1. art. 6.*). But matter is defined through

the order and relation to form — for it is the common subject of all forms. Therefore the aforementioned definition of matter is not suitable.

I distinguish the major: of what is total and perfect absolute, I concede; of what is partial and imperfect absolute, I deny. As is clear from the soul, which (2. *Anima T. 1. and T. 6.*) is defined through order and relation to the organic body: "The soul is the first act of an organic body." A part, however, as a part regards its co-part; and the one is relatively opposed to the other — as Fuentes notes (1. *Phys. q. 5. dif. 1. a. 1. n. 3. and 10.*) after Aristotle (2. *Phys. T. 26.*).

Article III. Whether Matter Is Substance.

The affirmative part seems so certain that the earlier philosophers cited by Aristotle (1. *Met. c. 3.*) held the whole substance of the substantial composite to be matter alone, the rest being accidents; and consequently that substantial composites differ only accidentally — e.g., the elements in rarity or density, and the rest in the manner previously indicated above (1. *Phys. c. 5. and 6.*). Later philosophers, however, even if they place matter among substances, think it a partial and incomplete substance from which, together with form, the composite is constituted — which is a total, complete, and perfect substance. Hence substance is distributed into total — which is the composite — and partial — which is subdivided into matter and form: the former is perfectible, indifferent, and indeterminate to receive all forms; the latter is perfecting, determining, and actuating matter. Therefore from both — as perfectible and perfecting, actuable and actuating, or, as commonly said, from potency and act — something one per se comes to be, which is the substantial whole, as Aristotle clearly sets forth (2. *Anima T. 7. and 8. Met. c. 6. T. 15.*).

Assertion I. Matter is substance. So Scotus (2. *d. 11. q. 1.*). It is proved first from Aristotle (2. *Anima T. 1.*) and (7. *Met. c. 3. T. 7.*), dividing substance into matter, form, and composite. Secondly: substance is divided into simple and composite; but composite substance, as it is distinguished from simple, is composed only of matter and form — because substance is made from substances (1. *Phys. c. 6. T. 52.*). Otherwise all substantial composition would be removed, which requires substantial parts, one of which is matter and the other form. Substantial corruption too would be removed — which leaves behind a certain surviving substantial part; otherwise it would not be corruption but annihilation. But the substantial part that remains after the corruption of the composite is matter. Therefore matter is substance.

Assertion II. Matter is a partial and incomplete substance. The Doctor defends this (*ibid. § Dico igitur*) and (*§ Sequitur.*). It is urged first from Aristotle (2. *Phys. T. 28.*) and (5. *Met. T. 2.*): matter is an intrinsic cause of the composite. And (7. *Met. T. 7. c. 3.*): matter is a part of the substantial composite. Therefore, per Aristotle, matter is a partial and incomplete substance. Secondly: the parts of a whole are imperfect, since they are ordered to completing and perfecting it. But matter is

a part of the composite — because from this and form the whole is composed (7. *Met. T. 7. and 9.*). Therefore matter is a partial substance. Thirdly: a composite is one per se, consisting of perfectible and perfecting, receptive and received, determinable and determining (8. *Met. T. 15. and 16.*); and in this it differs from those that are one by aggregation or by order. It follows therefore that matter is a partial and imperfect substance.

Objection I: Against Assertion I — The receptive of some genus is nothing of that genus of which it is receptive, as is evident in the individual genera of accident. For the receptive of color is not in the genus of color — for color is in the category of quality, while its immediate subject is a surface, which belongs to the predicament of quantity. Therefore the receptive subject of substantial form, which is matter, does not reside in the genus of substance; and thus matter is not substance.

I respond: the major is not universally and perennially true. For every genus has its own potential and actual — so that, e.g., whiteness, though it is a simple form, is yet composed from intrinsic principles (12. *Met. 2.*). In this way the receptive of some genus is in the same genus reductively — as indeterminate quantity has its own potential in the genus of quantity. The reason why the receptive of color is not in the same genus but in the prior genus of quantity is that color participates in the potential which, according to the whole genus, is prior to the whole genus of color. But since substance is the first genus, its receptive — which is matter — is of the same genus reductively.

Objection II: Matter is called near-nothing, as Augustine says (12. *Conf. c. 32.*), so much so that nothing is closer to nothing than matter. But substance is a being subsisting per se, as is clear from what was said in the Logic (*l. 3. q. 4. a. 1.*). Therefore matter is not to be placed among substances.

I respond: matter is called near-nothing not because it is not a true, real, positive, substantial being — but because among substances it holds the lowest place and is perfectible, lacking all form, perfection, and beauty — as the same Augustine clearly shows (*cit. c. 3.*).

Article IV. Whether Matter Is Created.

Some — among whom Aristotle is numbered, as Vorrlong (2. *d. 1.*) testifies, and others cited by Suárez (*disp. 13. Met. Sect. 4. n. 15.*) — think that matter is ungenerated and uncreated, calling it chaos from which they suppose all things were made. But the common opinion of Scotus (2. *d. 12. q. 1.*) and other scholastics there is that matter is created.

It must be presupposed from what will be said in the book on the world and in the Treatise on Creation (*disp. 1. q. 1.*): that creation properly so called is the production of a thing from nothing — that is, with no presupposed subject and no pre-existing matter. Therefore it is adapted solely to God, who is from

himself and independent. Other agents, since they are dependent, require a subject and presuppose matter in order to be able to exercise their operations.

Assertion. Matter was created by God. It is proved first from Augustine (*l. de natura boni contra Manich. c. 18.*) and (*l. 12. Conf. c. 7.*), where addressing God he says: "You were, and there was nothing else. From what did you make heaven and earth? Two things, one near to you, and the other near to nothing." This means, according to Scotus (*4. d. 12. q. 6. § Quarta opinio B.*): matter, which is properly called nothing — not absolutely (for it is substance), but relatively (when compared to soul and body), and because it lacks all species, it is called nothing — as the same Augustine testifies (*l. 83. qq. q. 54.*). And in the same book of Confessions (*c. 8.*) the saint himself subjoins: "For you, O Lord, made the world of formless matter, which you made from no thing." He repeats the same (*l. de vera religione c. 18.*): "if the world was made from some formless matter, this itself was made wholly from nothing." Secondly: what properly comes to be, does so either through creation or through generation. But matter cannot come to be through generation; therefore it comes to be through creation. The major is evident — for no other mode of producing is found besides those two. For either a thing is produced without a pre-existing subject, and comes to be through creation; or from a presupposed subject, and comes to be through generation. The minor is urged: matter is the subject of generation, or the fundamental presupposition of generation — as the Doctor (*cit.*) says. For generation is a mutation that always requires a subject. Moreover, Ferchius shows at length (*vest. 1. c. 8.*) that there is no repugnance on the part of matter against having been created by God, and proves with many arguments that this is the opinion of Aristotle — which I shall evaluate elsewhere.

Objection: "From nothing, nothing comes to be" — according to the common decree of physicists (*11. Met. c. 5.*). But creation, as has been said above, is a making from nothing. Therefore matter was not created.

I distinguish the major and interpret that maxim as holding through the power of a natural agent, which in acting depends upon a subject — I concede; through the power of a supernatural agent, which is independent and can act without a presupposed subject — I deny. And Augustine confirms this (*1. de Gen. ad lit. c. 15.*): "There is no doubt that this formless matter is so near to nothing that it was not made except by God, and that together with the things that were made from it, it was fashioned at the same time."

Article V. Whether Matter Has an Entitative Act.

Two most noble schools dispute strenuously about the proposed difficulty: one — that of St. Thomas (*1. p. q. 66. art. 1.*) and his disciples Capreolus, Ferrariensis, Cajetan, the Complutensians (*in praesenti disp. 3. q. 2. § 2.*), Baconius (*2. dist. 12. art. 2.*), Zabarella (*l. 2. de materia c. 2.*), and Rubio (*Tract. 1. de materia q. 2.*) — who affirm that matter is such a pure potency that it includes no entitative act. The

other — that of Scotus (7. *Met.* q. 5.) and (2. *d.* 12. q. 1.) and (4. *d.* 11. q. 3.), and of Antonius Andreas, Mayr (*ibid.*), the Parisians (1. *Phys.* fol. 25. q. 2.), Hurtado (*disp.* 2. *Phys.* sect. 2. § 24.), Arriaga (*ibid.* Sect. 5. subsect. 1.), Suárez (*disp.* 13. *Met.* Sect. 4. and 5.), Fabri (*Theor.* 22.), and other Scotists and Nominalists — who teach that matter is not pure potency but has an entitative act.

First Note, from Scotus (7. *Met.* q. 5. § *Responsio.*) and (q. of the same work q. 2.) and (2. *d.* 12. q. 1. § *Est igitur videndum.* B.), Baconius (*ibid.* d. 1. q. 5.) following Aristotle (7. *Met.* T. 56.) and (8. *ibid.* T. 15.), and also (q. of the same work T. 13.) and Augustine (12. *Confessionum* T. 32.): potency is divided into objective and subjective. Objective potency is that which regards what is producible and makeable — by effective potency; just as a rose presently not existing is in objective potency to be caused by its cause, as its object and terminus. And this kind of potency is rooted not in the passive potency of matter but in the active potency of the agent. Subjective potency, however, is that by which something is capable of receiving a form — thus a wall participates in the subjective potency to receive whiteness, and an organic body to receive a soul. But Scotus (*cited in* 2.) adds that perhaps these are not absolutely two potencies, but one and the same, only relatively diverse — for insofar as it regards an existing subject, it is called subjective potency; but insofar as it regards the agent, it is called objective. Nevertheless they can be separated from one another — for what is creatable is in objective potency but not in subjective potency, since creation presupposes no subject. But what is in objective potency is not something real actually existing, since it is producible and makeable by an agent; it is in fact pure nothing in act. But what is in subjective potency is something real actually existing caused by an efficient cause. For a wall would not receive whiteness in itself unless it actually existed — since the subject must pre-exist and be presupposed for those things that are received in it. Hence the Doctor well says (*Quol.* 10. § *De secundo ante G.*) and (3. *d.* 13. q. 4. L.): matter is prior to form, because it is the subject and foundation of form, in which it is founded and originates.

Second Note: potency is opposed to act — from Aristotle (9. *Met.* ad T. 10.) and Scotus (2. *d.* 2. q. 10. § *Ad 1. H.*). Therefore a twofold act is opposed to the twofold potency just recounted — namely, the entitative and the formal. The entitative act is that by which a thing has existing being outside its causes — for it is derived from being; and therefore that is said to have an entitative act which has a being caused by an efficient cause and actually exists. The formal act, however, is that by which something is constituted in specific being and distinguished from every other that is not itself — for form is said to be what confers upon a thing its specific and essential being. From this it follows that "to be in act" is commonly attributed to form and appropriated to it — because it determines, specifies, and distinguishes a thing. Matter, however, because it receives form and is in potency to receiving it, and is itself determined by form — for this

reason is said to be, and is defined as, potency (2. *Phys. T. 12.*), and (5. *ibid. T. 8.*), and (8. *Met. T. 3.*). And the Doctor intimates this (*l. de 1. principio c. 2. concl. 6.*).

Third Note: just as subjective potency presents two things — namely, aptitude in the subject and the privation of the form to be received (for that is said to be in potency which is fit to receive a form that it lacks) — so potentiality can designate two things: namely, the aptitude to receive form — which is a certain real and actual entity, whatever Bacconius may say (2. *d. 12.*) — and the negation of form and act, in which way potentiality is not a real and actual entity, and indeed is distinguished from actuality itself as privative from positive. Hence the dilemma of Bacconius is easily dissolved, who says: "either the potentiality of matter is actuality, or it really differs from actuality." To this one satisfies by responding that potentiality is radically and really an actual entity, really differing from the actuality of form — since just as it has its own being, so it has its own entity. Nor is it rightly inferred from this that matter is composed of actuality and potentiality — since potentiality follows from matter as a property from its subject, or as a relation from a foundation, as the Doctor indicates (1. *d. 7. q. un. § Ad quaestionem sub. L.*).

Assertion. Matter is not pure potency but has an entitative act. Scotus holds this (*loc. cit. at the beginning of this article*), and urges it from Aristotle: (1. *Phys. T. 52.*): "Matter is per se a principle of natural things." (2. *Phys. T. 7.*): "Matter is nature." (5. *Met. T. 2.*): "Matter is per se a cause." (7. *Met. T. 28.*): "Matter is a part of the composite substance." (1. *Phys. T. 82.*): "Matter is the subject of forms." And (1. *Met. T. 17.*): "Matter is the foundation of nature." But matter cannot exercise these and similar functions unless it is a real actual entity — for a principle does not principiate, nor does a cause cause, nor does a nature naturate, nor does a part compose, nor does a subject receive a form, nor does a foundation found those that are built upon it, unless it is actually a real being. Therefore in the school of Aristotle and of truth, matter possesses an entitative act. The same Augustine intimates (*l. de natura boni contra Manich. c. 18.*) and (*l. 1. contra Advers. legis et Proph. c. 8.*) and (12. *Conf. c. 7.*). The same truth, pressed by it, Thomas seems to confess (*q. 3. de veritate art. 5. ad 1.*), saying that matter's being is to have an imitation of the first being — which means nothing other than to be in act, which belongs to God, who alone is said to be most actual. Therefore matter imitates God — not in potential being, which is far from him, but in actual being, which belongs to God independently. Nor is it valid what the Complutensians add (*disp. 3. q. 2. § 3.*) — that Thomas meets the instance by saying that matter has a weak and lowest being. For although matter's being is weak and feeble, it nevertheless participates in actuality, in which it imitates and is assimilated to God — as the said Doctor intends.

The Thomists respond to all the aforementioned passages and testimonies by saying that matter performs all the functions listed as it is potency, not as act — of which it is devoid. For since matter is essentially potency, and being is

divided into potency and act, matter is consequently comprehended not under actual being but under potential being.

Against this: matter is either objective potency or subjective potency, since no middle is intercepted between the two — just as between being and nothing. Not the first — since matter is not nothing, but exists as the terminus of objective potency, whose being is fulfilled and terminated through such potency. If the second — then matter possesses an entitative act. And the Thomists — notably the Complutensians at the end of (§ *cit.*) — unwilling to do so, fall into the position of Scotus, who asserts that matter is subjective and receptive potency for forms. Moreover: (2. *Phys. T.* 69.), (2. *ibid. T.* 86.), (1. *de partibus c.* 1.), and (2. *de gen. T.* 57.): just as artificial matter stands in relation to artificial forms, so natural matter stands in relation to natural forms. But the potency by which artificial matter is able to receive artificial forms does not remove its actual being. Therefore neither is the actual being of natural matter removed, even though it presents an order and relation to receiving natural forms.

Again: matter actually exists in the order of things, since it was established by God and always perseveres. Therefore it possesses the act that is called entitative act — as Aristotle not obscurely indicates (7. *Met. T.* 59.).

The assertion is proved secondly: what actually terminates the actual dependence of some actually existing being is an actually existing being. For it cannot terminate the actual dependence of that being unless it actually exists — since termination presupposes the existence of what terminates, just as a relation presupposes that which is related to another. But matter terminates the actual dependence of form — since form is educed from it and is subjected in it. This cannot be unless matter itself actually exists. Therefore matter has an entitative act.

Thirdly: what actually inheres in a composite must actually exist — since it is prior to exist than to inhere, just as it is prior to be than to inhere. But matter inheres in the composite, since it is its essential part, from which together with form the composite itself actually comes to be. Therefore matter is an actual entity and therefore enjoys an entitative act.

Rubio (*Tract. 1. q. 2.*) responds that real entity is divided by Aristotle (9. *Met. T.* 1.) and (6. *ibid. T.* 4.) into act and potency; and therefore the inference from the divided to one member of the division taken per se does not hold — just as it does not follow: "it is an animal; therefore it is rational." Against this: as the Doctor says in the exposition of the text, that division of being into act and potency is a distracting division — such as "another man is real, another is painted." But a painted man is not truly a man; so being in potency simply is not being. But matter properly is a being, since it is a substance and an essential part of the composite. Therefore it is not contained under that member of being in potency, but under the other — namely, actual being.

Furthermore, Rubio himself (*cit. q. 3.*) asserts with Scotus that matter has its own existence independent from the existence of form and composite. Therefore it participates in its own entity — since existence follows upon essence and entity. For nothing exists unless it has being. Moreover, the said Rubio, to prove that matter possesses its own existence, says this is deduced from the principles of Aristotle, who teaches three things about matter: one, that it is a real and actual entity outside its causes, distinct from any form and composite; another, that it is the primary subject of every generation; and a third, that with all forms and composites destroyed, it perseveres — and therefore is ingenerable and incorruptible. But all these things cannot be said of pure potency, since they belong to something actual and existing. Therefore Rubio is inconsistent with himself.

Nor does it avail to say with the aforementioned author (*cit. q. 3. in resp. 2.*) that matter is pure potency in terms of essence but not in terms of existence — since essence and existence are one and the same thing participating distinct formalities, which Rubio and other Thomists do not concede. If, therefore, matter in terms of existence is an entitative act, then equally so in terms of essence. All the more so since they cannot be separated from one another, as they are formally distinct from each other only.

Finally: the matter of sublunary things, in the school of St. Thomas, differs in species from the matter of celestial things. But such a difference is in terms of essence and act. For difference actuates and determines the thing of which it is the difference. Therefore matter also in terms of essence possesses an entitative act. Nor does it help to say with the Complutensians (*cit. q. 3. § 2.*) that only a negative difference exists. For the constitutive difference of something positive is the real constitutive principle of it — as the rationality of man and the irrationality of a brute; therefore it must be established absolutely that matter possesses an entitative act.

Objection I: What enters in the nominative into the definition of something is its essence or belongs to its essence — for a definition denotes and explains the essence of a thing. But potency in the nominative is placed in the definition of matter. Therefore matter is pure potency. The major is evident. The minor is supported by the testimonies of Aristotle, especially (8. *Met. c. 2. T. 5.*): "Matter is potency." And (12. *ibid. Met. c. 4. T. 22.*): "Matter primarily and per se is potency." And that saying is on everyone's lips: "a composite comes to be from act and potency." Hence (7. *Met. T. 8.*) the same Philosopher adds: "Matter is not what, nor how much, nor any of those by which being is determined." Scotus agrees (1. *Post. q. 25. § Aliter dicitur.*), where these words are found: "Matter is of itself in passive potency, including no act in its essence." He writes the same (*q. 15. Elench. § Ad quaestionem dicendum.*).

I concede the major. I distinguish the minor: matter is objective potency — I deny; subjective — I concede. To the subsumption from (7. *Met.*) it has already

been dissolved and explained above in Article II, Doubt X, in the response to the first objection — namely, that matter is an indifferent and indeterminate being for receiving forms. To Scotus: I say either that his cited passages admit the distinction drawn about potency, or that he speaks there in the view of others — as the Angelic Doctor similarly notes, and after him Bargius (9. 3. *prol.*).

Objection II: Act actuates and distinguishes — and because form is act, it is therefore said to give being to a thing and to distinguish it from every other thing. But matter neither actuates nor distinguishes, since it is the foundation of nature in which nothing is distinguished (1. *Met. T. 11.*). Therefore matter is neither act nor something having act.

I distinguish the major: formal act — I concede; entitative act such as matter is — I deny. To the minor I say that matter has a distinguishing act metaphysically, not however physically — as is evident from the rational soul and from angels, who are without matter and form, yet obtain a distinction from one another that is metaphysical — some differing in species, others in number — as I showed at length in the Treatise on Angels (*disp. 1.*).

Objection III: From two beings in act there does not come one per se (7. *Met. T. 19.*) — for form accruing to a being in act is accidental. But if matter were an entitative act, from it and form as from two acts there would come one per accidens — which conflicts with (T. 59.), where it is found that from potency and act one per se comes to be — that is, a composite coalesces from matter and form. Therefore matter is stripped of every act, even the entitative.

I respond with Scotus (3. *dist. 22. q. un. § contra ista. H.*) by distinguishing the major: in complete and perfect act — I concede; in incomplete and partial act — I deny. For from an entitative act that is partial and incomplete, and from a formal act likewise partial and incomplete, a composite is composed that is one per se.

Objection IV: There is pure act excluding every potency — both objective and subjective — such as God. Therefore there is also pure potency, from which all entitative and formal act is remote — such as matter.

I concede the antecedent and deny the consequence. The reason is that although the highest good is given, yet the highest evil is repugnant — as the Doctor notes (2. *dist. 34. q. 1.*). For what is, participates some entity, and therefore some goodness — since every being is good. Similarly, pure potency having no actuality whatsoever is not admitted — because every uncreated and created being has actual and existing being, if it is actually in the order of things.

Article VI. Whether Matter Has an Existence Distinct from the Existence of Form

From what has been said in the preceding article, it is clear enough what must be held in the present question. Nevertheless, so that the truth of Scotist

doctrine may stand out more distinctly and shine forth more precisely, I wish to examine this article carefully and investigate it diligently. Presupposing what I brought forward and explained in the cited article, I note here only that the more celebrated and reliable Thomists agree with the Scotists in this: that by "entitative act" they understand existence, so that to inquire whether matter has an entitative act is the same as to investigate whether matter enjoys an existence distinct from the existence of form. I further presuppose from Metaphysics that essence and existence are really identified, and are distinguished only formally and negatively, as a mode from the thing modified.

LXIX. Affirmative position: matter participates in an existence distinct from the existence of form. So holds the Doctor and his disciples, and the Nominalists, at the step previously recalled, supported by the greater part of recent authors.

Against the Thomists: Cajetan, (*lib. de ente, & essentia capit. 5. quaest. 8.*)

Ferrariensis, (*1. contra Gentes capit. 4.*) Soncinas, (*capit. 7. Met. quaest. 17.*) and the Complutenses. (*1. Phys. disput. 3. quaest. 5. §. 2.*)

It is proved first: matter is the foundation of natural being (*1. Met. 17.*) and the subject and receptacle of forms, (*1. Phys. 82.*) as well as a part and cause of the composite. (*5. Met. T. 2.*) But matter cannot perform these functions unless it exists by its own proper existence. Therefore matter has an existence distinct from the existence of form. The major is clear. The minor is easily proved: a subject cannot receive anything into itself unless it exists, nor can a cause produce an effect, nor can a part compose a whole with its co-part, unless they exist — for actions belong to singular existing and subsisting things, (*1. Metaph. 1.*) as even the adversaries do not deny.

The Complutenses respond, (*nunc alleg. §. 4. ad 4.*) granting the major and denying the minor: it is sufficient for matter to perform those functions provided it has its own potential essence, which really differs from existence. In that case, matter has being in via, or in process of emerging, which is not properly to exist, since existence is the ultimate term of a thing. In that prior state, matter is directed toward form and toward the composite, and therefore has no existence except what is borrowed from form.

Against this: a cause that is actually causing actually is; but whatever actually is, actually exists. For "to exist" and "to be in act" coincide. But matter actually is, because it actually causes and composes, and from it form is drawn out by an agent; and from it together with form the composite comes to be. The argument is therefore not dissolved but evaded, and there is a contradiction in terms to say that matter actually is a cause because it truly causes, and yet does not actually cause, since according to them it does not exist through those acts. For whatever is outside of nothing and outside its causes, exists. But matter, insofar as form is drawn out from it and it concurs partially in causing the whole, is outside of nothing and outside its causes, truly created by God from nothing, since it is the terminus of creation. Therefore it exists by true and

proper existence. Moreover, to say that it then has *esse essentiae* but not *esse existentiae* — being of the way but not being of the term — is ridiculous and empty. For if its essence is in act, because it is actually produced by an agent, it truly exists, since existence is the actuality of the thing. It is contradictory to say that its essence is in act and yet its existence is not, since for a thing to be in act is its existence. But the essence of matter is conceded to be in act because it is in *via*, and what is in *via* is in act; therefore its existence too must be admitted. For to be in act is nothing other than to exist.

LXX. Nor does it help to say that existence is the ultimate term of the thing, and that matter is then tending toward form and toward the composite. For even if it exhibits such order and relation, it does not follow from this that it is not in act — on the contrary, it is in act precisely because it is ordered to something else. A thing must first be in act before it can be ordered and related to another. All that is inferred, therefore, is that matter has incomplete and imperfect being, and that its existence is incomplete and partial, tending toward its complement and its specific being, which it obtains through form. And this is what those authors seem unwillingly to concede when they say that its being is *vialic* and in a state of emergence — and therefore from it together with form there arises the ultimate term, which is the composite, the complete and perfect being, whose existence is said to be its ultimate term. All the more so, since the rational soul, separated from the body, enjoys its own proper existence, even though it inclines toward the organic body, which is its matter.

Second: matter is the common subject of form and of its privation. These two natural principles are found in it successively, since it is the subject of natural change and remains under each extreme. Therefore it exists as ingenerable and incorruptible. (*1. Phys. cap. 9.*) But this it cannot be unless it exists by its own proper existence. Therefore matter enjoys its own existence independent of the existence of form. The major is clear. The minor is admitted. Matter, as it stands under privation, is actually, since privation exists in it — just as darkness is in air when light is absent — and after privation, form arrives. Just as a vessel exists that receives water, so matter actually is when it receives form. But to be actually is nothing other than to exist. Therefore, since matter is actually, because it underlies privation and form, it plainly follows that it truly exists without the existence of form. Certain Thomists respond that matter is only the subject of both aforementioned principles with respect to essence, not with respect to existence, which it derives from form.

LXXI. Against this: the mind of Aristotle and the other philosophers who assert that matter is the subject of natural change is that it is such a subject not only with respect to essence but also with respect to existence. For they say that forms are drawn out from matter itself; but forms are not drawn out by an agent from matter as possibly existing, but as actually existing in the nature of things — since forms are drawn from it as already created by God, not as possibly able

to be created, and the material forms themselves depend on that same matter in their being and in their becoming. But what depends on another is presupposed to exist and to stand in itself — which is what the word "existence" denotes. Especially because, (1. *Phys.* 69.) matter in natural things is related to natural forms as the matter of artifacts is related to artificial forms. But the matter of artifacts undoubtedly has its own existence, as is clear from wood, which is the matter for making the figure of Mercury. Likewise, therefore, the matter of natural things possesses its own existence.

Furthermore, the subject of accidental forms properly exists, as a wall in which whiteness is received. The same must be asserted of the subject of substantial forms, which is matter. Moreover, when the rational soul is separated from the body, which is its matter, the body truly exists — not by the existence of the soul, which is supposed to be far distant from it, nor by the existence of another form, since the Thomist school does not recognize any form in a human being besides the soul. Therefore the body, which is the matter of the soul, possesses its own existence without the soul.

LXXII. The Complutenses respond (*ubi supra ad 2.*) that matter exists not through the existence of the preceding form but through the existence of the subsequent form. Therefore matter is never without existence, but at one time coexists under the existence of one form, at another time under the existence of another form — just as the same light persists, even though it is conserved not by the luminous body that produced it but by another.

Against this: at the moment when the preceding form departs, privation is present, and the subsequent form has not yet arrived — matter is actually, since privation is in it, and from it a new form is to be drawn out or introduced. Therefore matter then exists, not by the existence of the old form nor of the new, since neither is there present; therefore by its own proper existence.

Furthermore, matter would not persist as the same throughout natural changes, but just as the prior form perishes because its existence fails, so the existence of matter would perish when the prior form perishes. But it is false that matter ceases to be, since it is incorruptible. Therefore it is also absurd to deny it its own proper existence. Nor does it help to say that it is destroyed with respect to existence but not with respect to essence — for the same could be said of form, which would fail with respect to existence but not with respect to essence, since the reasoning seems equal in both cases.

Again, when the rational soul is separated from the body, the existence of the body would not cease, since the soul itself would exist as separated — and from the soul, which is its matter's form, the body derives its existence, according to those authors. I add that in local motion the subject of motion actually exists; in artifacts the foundation of them likewise exists, as is evident in houses and city walls. Therefore, since matter is the foundation and subject of natural forms, it

must of necessity exist of itself. The example of light is not to the point. For it belongs to the genus of efficient cause, and it ought to have been brought forward under the genus of formal cause, as existence is — which proceeds from essence as a mode from the thing modified, as Aversa notes among others.

Third: things produced by distinct actions enjoy distinct existences, because a distinct action is directed toward a distinct existing terminus — as the Thomists do not deny. But matter and form are produced by distinct actions. For matter comes forth through creation, and form through generation. Therefore matter obtains an existence distinct from the existence of form.

The Complutenses respond (*praeal.*) granting the major and denying the minor: matter and form are not produced per se separately, but co-produced toward the production of the whole. Against this: matter is the terminus of creation, as Augustine writes, (*lib. de natura boni, contra Manich. c. 18. 12. Conf. capit. 7. 8.*) and form is the formal terminus of generation, as I showed (*quaest. 1. artic. 3. huius lib.*)

Furthermore, if God were to produce form first — as the rational soul — before its matter, and they were then united simultaneously, they would be produced by distinct actions and enjoy distinct existences, corresponding to distinct actions.

I conclude therefore that matter participates in a proper existence distinct from the existence of form, as the arguments brought forward prove — admitted by the Conimbricenses (*1. Phys. cap. 9. quaest. 6. art. 2.*) and received by Suárez (*disp. 15. Met. Sect. 8.*) as true doctrine.

LXXIV. Objection I. In several places, notably (*1. de gener. T. 22. 2. Phys. T. 12.*) and (*5. Met.*) Aristotle says that form gives being to a thing. Boethius writes the same (*1. Trinit. capit. 2.*) and Dionysius (*lib. de divinis nominibus capit. 3.*) uses these words: "To exist is the most perfect effect, which seems to be the effect of form." I explain the cited testimonies by the following distinction: of specific and complete being and existence, I grant; of partial and incomplete being and existence, I deny.

LXXV. Objection II. Being exists for the sake of operation. (*2. Caeli 7. 17.*) But matter issues forth no operation, since it is only passive and receptive; therefore neither does it have any existence. I respond that the major is not universally true, for relations have being even though they are not active. To the minor I say that the proper passions of matter arise from it, and from it the composite is also partially caused.

LXXVI. Objection III. If matter had a certain, determinate, and proper existence, it would be determinate in species and would be individuated by an individual difference. But this is seen to be false, because specific being comes from form. Therefore matter by its own nature is devoid of existence. I grant

the conclusion of the major. I distinguish the minor: in incomplete and partial species, I grant — which Scotus also teaches of the rational soul, which is a part of the human being, (2. *dist.* 1. *quaest.* 6. *conclusio ante A.*) But in complete and total species, I deny. For this is derived from form, as was to be said above with Aristotle. Furthermore, I grant that matter is individuated by its haecceity, as the same Doctor proves. (*cit. dist.* 3. *quaest.* 6.)

Article VII. Whether Matter Has Partial Subsistence

LXXVII. Those who deny existence to matter also take subsistence away from it — of which subject there is full and precise treatment in the *Metaphysics*. But since this difficulty seems to rest on an equivocation, the Scotist school notes (*Quod.* 4. §. *contra illud M. & Quol.* 5. §. *Ad 1. istorum. V.*) that the name "subsistence" is equivocal and offers three senses of it. (*Quol.* 9. §. *de secundo. A.*) After him, Bassolius (2. *dist.* 12. *quaest.* 1. *art.* 3. *ad 3.*) and Trombeta (*in initio Form.*) who dispute this question in proper terms:

First, it is taken for the per-se-ness or existence of something without coexistence with another — so that whiteness not actually inhering in a subject is said to subsist per se or exist per se, because it does not actually depend on a subject, even though it has an aptitude to depend on it. The Stagirite mentions this (1. *post.* 9.) by adducing the third mode of per se predication, as "whiteness is." In this sense, the accidents of the Eucharist subsist and exist per se, since they are actually sustained by no subject — as Hurtado frankly admits. (*disputat.* 5. *ante sect.* 8. §. 128.)

Second, it is taken for the per-se-ness and existence of something existing without any actual or aptitudinal inherence in a subject. In this sense every substance, both complete and incomplete, subsists per se, because it neither actually nor by aptitude inheres in a subject. Even though it exists in another, as a part in its co-part — as form in matter — it does not exist in it by inherence but by information, since it is act simply speaking. Therefore from both together there arises one per se thing, which is the composite; whereas an accident, which is in a subject by inherence and is act only in a qualified sense, therefore makes only a per accidens one with the subject and subject together (8. *Metaphysica* 10.) — and by this, accident is distinguished from substance. This sense is mentioned by St. Athanasius in the debate held against Arius at the Council of Nicaea.

Third, for incommunicable existence to another, and not ordainable to another act simply speaking, since it is the ultimate actuality of the thing both as quo and as quod. This is cited by the Doctor. (1. *dist.* 23. *quaest. unic.* §. *Ad quaest. respondeo ante C.*) What subsists by this subsistence is called, in irrational nature, a suppositum or hypostasis; and in rational and intellectual nature, a person. This is the more strict and proper sense of subsistence, as the Doctor notes. (*Quol.* 4. & 5. *pranom.*)

LXXVIII. Affirmative position: matter participates in partial subsistence taken in the first and second senses, but not in the third. This is drawn from the Scotists (*ubi supra in 2. memor.*) against Vásquez. (*1. p. Tom. 2. disput. 147.*) The position is threefold.

The first part is urged as follows: First, from what will be said in the next article, matter can by divine power exist without form, and therefore also exist per se and not be sustained by another. Second, an accident that does not rest on a subject subsists in this first sense, as I declared above. But matter can exist by itself alone, just as an accident in the Eucharist exists per se; therefore it also subsists in the first sense.

LXXIX. The second part is proved as follows: First, every substance subsists in the second sense. For in this it differs from accident — since accident actually or by aptitude requires a subject, whereas substance, whether complete or incomplete, is immune from all inherence, both actual and aptitudinal. Therefore, since matter is a substance, it subsists by this subsistence. Second, "substance" is derived from "subsisting," as I noted with St. Bonaventure (*1. dist. 23. quaest. 2.*) in the Epitome. (*lib. 1. quaest. 4. artic. 3. numer. 9.*) Therefore, since matter is a substance, it is not deprived of this mode of subsisting — especially because it is the subject and vehicle of forms, which undoubtedly requires subsistence taken in the second sense.

I am not unaware that some concede this kind of subsistence to matter while denying it to form, except the rational soul — as two of our more recent authors do (*disputar. 2. quaest. 2. artic. 2.*) who combat above all Scotus, who expressly teaches (*Quol. 9.*) that substantial form subsists in this sense without qualification, and gives the reason, saying: "Substantial form, although it is in matter by informing, does not however inhere in it — because to inhere means not to inform per se, since what inheres is not act simply speaking, and does not make a per se whole with that in which it inheres; the opposite holds of what informs per se." It is clear, then, according to Scotus, that form subsists in the second sense, because it differs from accident, which is in a subject by inherence; whereas form is in it by information, as a part in its co-part, from which together a whole is constituted that is one per se — whereas from accident and subject there arises only a per accidens one. Again, according to Scotus in the same place, what subsists per se in this sense is what is supported by no subject either actually or by aptitude; but substantial form of whatever kind neither actually nor by aptitude inheres in a subject or in matter — since substance differs from accident precisely in this. Therefore this subsistence is wrongly denied to it.

LXXX. One might say: form that is drawn out from the potency of matter does not subsist, because it exhibits dependence on matter. Against this: the aforesaid subsistence excludes only inherence, as Scotus declares in the same place; therefore, even though form depends on matter, it does not lack that

subsistence. Moreover, if form were separated from matter by divine power, it would exist *per se* independently of matter. Even though form actually exists in matter, it is not stripped of the said subsistence. Furthermore, integral parts, even though they are in the integral whole, nonetheless do not lose their subsistence. The same must be said of the essential substantial part, such as form existing in matter. Finally, every substance depends on God, but notwithstanding this dependence it possesses its own subsistence; and therefore, even though form depends on matter, it is not on that account without proper subsistence, which flows from it as a mode from the thing modified.

LXXXI. The third part is shown as follows: First, from (2. *animae capit.* 2.) where Aristotle writes that the whole from matter and form is simply "this something" — which Scotus interprets as subsisting *per se*. There are added the Councils adduced by Molina (1. *p. disputat.* 3.) in which it is decreed that in the Holy Trinity there are three personal and incommunicable subsistences, and in Christ there is one subsistence of the Divine Word. The Greek and Latin Fathers, cited by Vásquez, agree unanimously in attributing proper subsistence to the composite nature, which is the whole totally from matter and form. Second, total and complete subsistence is incommunicable existence as *quo* and as *quod*, from Richard of Saint Victor, cited and explained by the Doctor in the passage cited. (1. *recens.*) This does not belong to matter or form, since they are communicable to the whole. Third, subsistence taken in the third sense is the ultimate term of complete nature, since it is that by which something ultimately subsists and is not directed to any further act simply speaking. And therefore, since the subsistence of matter tends toward composing and completing the whole together with form, it is plainly deduced that subsistence does not belong to matter in the third sense.

LXXXII. Objection I against the second part of the affirmation: Scotus (*Quol.* 4. *ad finem artic.* 2. *M.*) writes that there is a twofold subsistence — one that excludes inherence and inexistence in another as a part exists in a whole, and another that is the same as incommunicable existence — and neither subsistence belongs to matter: not the first, because it exists as a part in a whole; not the second, because it is communicable to the whole. Therefore no subsistence belongs to matter. I respond that Scotus there is replying to a testimony of Augustine saying that the divine essence subsists with a perfect and absolute subsistence common to the three Persons, just as the Godhead is participated by the three — and that in that place he teaches nothing about partial subsistence. But (*Quol.* 9.) he clearly states that matter and form subsist by partial subsistence, as we have explained.

LXXXIII. Objection II. Subsistence is the ultimate term of a complete and perfect nature, by which it is rendered incommunicable to another — as all scholastics confess with one voice. But the existence of matter is directed toward the subsistence of the whole, as a part toward the whole. Therefore no

subsistence is to be assigned to matter. I distinguish the major: total and complete subsistence, I grant; partial and incomplete subsistence, I deny. For subsistence is wider in extent than suppositional or personal being. Therefore it is not incongruous that the former is adapted to the part, and the latter to the whole. For subsistence taken broadly is divided into partial and total, and properly and strictly speaking total subsistence is subsistence, as Scotus notes. (*Quol. 9. Sub A.*)

LXXXIV. Objection III. Form is not subsistent; therefore neither is matter. The antecedent is proved: form depends in being and in becoming on matter, because it is drawn out from its potency. I deny the antecedent. To its proof I say that matter also depends on form with respect to specific being; and yet it retains its subsistence, which belongs to it by its very nature as a substance distinct from accident. Therefore, even though form is dependent on matter, it is not on that account without subsistence, which flows from it as a mode from the thing modified. I add that material form can by divine power exist separated from all matter; and given that hypothesis, it would subsist per se — not by a new subsistence accruing to it, nor by a new influx added to it, as will be shown below — but by the antecedent subsistence by which it subsisted while existing in matter.

Article VIII. Whether Matter Can Exist Without Form

LXXXV. The Thomists, with St. Thomas (*1. p. quaest. 66. artic. 1.*) and St. Bonaventure (*2. dist. 12. quaest. 1.*) joined by Aureolus and Durandus (*ibidem, quaest. 2.*) deny that matter can exist without form by either natural or supernatural power. The Scotists, however, with Scotus (*2. dist. 12. quaest. 2.*) Richard, (*ibidem, quaest. 4.*) and Gabriel (*quaest. 1. artic. 3.*) — to whom among the Thomists Scotus of the Physicists (*1. Phys. quaest. 6.*) and Báñez (*1. p. quaest. 66. artic. 1. dub. 2.*) adhere — teach that matter cannot indeed naturally be stripped of all form, but that supernaturally it can be separated from all form.

LXXXVI. Note I. Essence means nothing other than the nature and quiddity of a thing. For it is that of which a definition is given: a definition clearly declares the nature of a thing, prescinding from its actuality outside its causes. Existence, however, as it is distinguished from essence, is nothing other than the proper actuality of a thing outside its causes, of which the Doctor makes mention (*3. dist. 6. quaest. 1. B.*) — and it is called a mode of essence, formally negatively distinct from it. Therefore existence follows upon essence. Just as a thing has its own proper essence distinct from all others, so it enjoys its own proper existence. And thus, corresponding to the twofold essence — total and partial — there will be posited a twofold existence: total, which belongs to the composite, and partial, which belongs to matter and form.

LXXXVII. Note II. From the Seraphic Doctor, (*praecit. questione tertia.*) "matter" as sometimes called "formless" can be taken in two ways. In one way, by exclusion

of every form — both that of the elements and of the other things that adorn the universe. In this sense matter was never formless, as Hugo of Saint Victor (*libro primo de Sacramentis, parte prima, capite quarto,*) Boethius, (*1. Trinitatis, capite secundo,*) and other Doctors hold, as Richard attests. (*citata questione quinta.*) His reason is that matter and form are directed toward constituting the composite. Therefore, just as form never existed without matter, so neither did matter exist without form. In another way, presupposing the substantial forms of heaven, earth, and the rest, but excluding the other things that could be generated from the elements — in which sense some testimonies of the Saints may be explained, who think that matter was prior to form, that is, by priority of nature, not of time, as St. Bonaventure (*ubi supra, questione prima.*) and Scotus (*ibidem, questione secunda, §. Respondeo sub A.*) note, following Augustine (*duodecimo Confessionum.*) The reason is that matter is the subject and foundation of form, which precedes form and has priority of origin. In this sense, at the beginning of the world, the earth had not yet generated green grass, nor the water fishes, nor the air adorned with birds — as Augustine plainly suggests (*citato capite tertio,*) addressing God in these words: "Did you not teach me that before you formed and distinguished this formless matter, nothing was — no color, no figure, no body, no spirit, yet not absolutely nothing: there was a certain formlessness devoid of any species."

LXXXVIII. Note III. From Scotus (*1. distinctione 44. quaestione unica, §. Respondeo. A.*) a twofold power is to be distinguished in God: one ordained and another absolute. The ordained power is described as the principle of doing something in conformity with law, according to the order established by that law. The absolute power is the principle of acting apart from or contrary to that law, provided no contradiction is involved.

LXXXIX. First Assertion: by natural power, matter cannot exist without form. The Doctor holds this. (*2. distinctione 12. quaestione secunda, §. Ad primam rationem, ante G.*) It is proved first from the manner of operation of natural agents, which cannot introduce one form into matter without expelling the preexisting form. Hence arose that axiom cited by Aristotle: (*4. Phys. Titulo 17. & primo de generat. Titulo 17.*) "The generation of one thing is the corruption of another, and vice versa." The Doctor illustrates this. (*1. distinctione 27. quaestione 3. §. contra ista generatio, Ad C.*) Since therefore a natural agent cannot deprive matter of all form and leave it bare, it is plainly deduced that matter stripped of all form cannot exist.

XC. One might say, with Arriaga, (*disputatione secunda, sectione sexta, subsectione tertia, numero 116.*) that this argument does not press hard. For even if matter, once produced, is always conjoined with some form, this does not prevent it from having been created by God at the beginning of the world without form. Against this: Arriaga himself (*citat. numero 111.*) establishes, with the common opinion, that matter cannot naturally exist without all form. Yet he now adds

that it could have been created by God stripped of all form. But our dispute is not about what is possible — which will be established in the next assertion — but about what is in fact the case. If therefore, in fact, matter never lacked form, the argument brought forward effectively makes the case that, both now and at the beginning of the world, matter participated in some form.

Second: from the slightness and weakness of matter and form. For they are two partial entities that by their very nature tend toward a third and total entity, which is the composite, and neither can subsist without the other. For matter is the sustainer and subject of form; the one is perfectible, the other is perfective. But nothing naturally exists without its essential perfection. Since therefore form is the perfection and complement of matter, it follows that matter does not exist without it.

Arriaga attempts to break this argument too, (*ubi supra*,) saying that just as a hand can exist without a body, so matter can exist without form. Against this: matter and form are essential parts of the composite, but a hand is an integral part of the human body. Therefore it is no wonder if it remains without the body — especially since a hand severed from the body is not a hand except equivocally, as the Stagirite clearly teaches. (*1. Pol. c. 2.*)

Third: matter depends on form no less than a subject depends on accident. For both are subjects, with this difference: matter is the subject of substantial form, as a body is the subject of accidental form. But a body is never found without accident — for instance, quantity, quality, and the like, as experience makes clear. Therefore likewise matter does not exist without form.

XCI. Second Assertion: by divine power, matter can exist separated from all form. So Scotus (*1. 2. citat. §. Respondeo. A.*) proves as follows: Every prior thing that is absolutely, really distinct, and not essentially dependent on another can, by the supernal power of God, exist separated from it. But matter is prior to form, really distinct, absolute, and not essentially dependent on it. Therefore by divine power matter can exist without form. The major seems evident in that it contains what is really distinct from what is posterior. For if the prior were really identified with the posterior — as a property with its subject from which it flows — it could not be separated from it; what is absolute is posited in contradistinction to what is relative, which cannot formally exist without its correlative. "Not essentially dependent" is added to distinguish it from the composite, which, being essentially dependent on its parts, cannot exist without them. The minor is at hand: since matter is the subject of form, and form is drawn out from it, matter undoubtedly precedes form in nature and origin, is a substance, and does not essentially depend on it, since form is extrinsic to it, having its own entitative being independently of form.

XCII. The Thomists respond by denying that matter without form participates in any entitative being, whether of essence or of existence — since, being pure

potency, it derives all its being from form. Against this: beyond what has been efficaciously proved and evidently demonstrated in the preceding Article VI, that matter has its own proper essence and existence without form — even if matter derived its existence from form, it could still by divine power exist without it. For in the Thomist opinion, the humanity of Christ borrows existence from the Divine Word, and yet that humanity can exist without the Word. Therefore, even if matter derived its existence from form, it could still supernaturally exist without it. Possibly with this in mind, Augustine (*lib. 5. de gen. ad lit. capit. 8.*) says: "When someone thinks that what scripture records as having been done cannot be done, let him either pull back from the faith or not approach it." And it was decreed at the University of Paris, as Gadius reports, (*Quol. 16. artic. 1.*) that in things really distinct, essentially ordered, and absolute, by God's power the prior can exist without the posterior.

Second: accident depends on a subject no more than form depends on matter. But accident can by divine power exist without a subject. The minor is a matter of faith, for the faithful believe that in the Eucharist, the accidents remain without a subject. The major is shown: accident is posterior to subject, whereas matter is prior to form. But what is posterior depends more on what is prior than the prior depends on the posterior, since everything posterior has the character of being dependent, and what is prior, as prior, participates in the character of being independent. Again, to be per se belongs more to substance than to accident, since substance is a being subsisting per se, whereas accident inheres in another. But matter is a substance — for from non-substances, substance is not made. (*1. Phys. 53.*)

XCIII. The Thomists, notably Cajetan, (*adductus a Complut. citat. §. tertio ad secundum,*) respond by denying the parity, because accident has the character of an actual and complete act in its genus, whereas matter is an incomplete and potential being. Therefore accident can exist without a subject, but matter cannot without form. Against this: matter is more actual than accident, because matter exists per se whereas accident inheres in another — whence comes the axiom: "The being of accident is to be in another." Therefore the argument stands firm and unshaken.

Third: what God can immediately create, he can also immediately conserve. But God can create — and in fact immediately created — matter. Therefore he can conserve it without any form. The major is evident, since to conserve and to create matter are equally and of the same power, as will be said elsewhere. The minor remains proved in Article IV of this question. Furthermore, God is a free agent whose power is his will. But God can will to create matter without there being a form in it. Finally, God can destroy the form by which matter is informed and prevent a natural agent from drawing out another form from the potency of that matter — and given that hypothesis, matter would exist without

form. We conclude, therefore, that there is no incompatibility with matter being able to exist without form.

XCIV. Objection I against Assertion I. Genesis I: "The earth was void and empty" — that is, formless, as some explain that passage. Therefore in fact matter naturally existed without form, and therefore matter can by the forces of nature remain without form. I respond with Lyra that that passage is to be interpreted not of the matter of the earth but of the element of earth itself, which is composed of matter and form like the other elements. And so it is clear that earth was created by God with its own substantial form. Likewise, the celestial bodies were called formless at the beginning of the world not because they lacked their own forms but because they were deprived of some adornment. In the same sense, earth was said to be void and empty because it was not yet adorned with herbs, plants, and trees. Augustine seems to hold the same. (*12. Conf. cap. 21. & serm. 34. de tempore.*) For it was invisible and unformed, not yet ordered and filled with diverse fruits.

XCV. Objection II against Assertion II. What involves a contradiction is not contained under the object of divine power. But the real separation of matter from all form implies a contradiction. Therefore it is impossible for matter to exist stripped of all form. The major is the common assertion of theologians. The minor is clear: given the hypothesis, matter would be in act because it exists, and would not be in act because it is pure potency. But it is contradictory for the same thing to be in act and not in act. I grant the major and deny the minor. To its proof I say that matter would then be in entitative act, but not in formal act. Therefore there is no contradiction in matter having entitative act and being separated from all form or formal act.

One might press further: matter cannot exist without dependence on God, union of its parts, distinction from other things, and the other items enumerated by Canon (*1. Phys. quaest. 9. §. Ista opinio*) — and these are modes of form. Therefore it is impossible for matter to be separated from all form. Pontius (*1. Phys. quaestione 5. numero 81.*) grants this with respect to accidental forms, but denies it with respect to substantial forms. Against this: the difficulty in question applies not only to substantial forms but also to accidental forms, as can be seen from Scotus (*2. cit. §. Respondeo.*) And the arguments brought forward prove it for both kinds of forms. These instances, therefore, are to be handled differently, with Scotus (*ubi supra ante §. Ad argumenta, sub D.*) — namely, that those forms are really identified with matter and formally distinct from it, and are called transcendental, about which there is no difficulty here; the difficulty concerns physical forms really distinct from matter, absolute and non-relative, among which are not included union and the other items listed by the aforesaid Pontius.

XCVI. Objection III. The more united things are, the less separable they are from one another, compared to things that are less united. But matter and form

are more one than a subject and its property, since from matter and form there arises one per se thing, while from a subject and its property there arises only a per accidens one. Therefore matter cannot in any way be separated from form. I grant the major. I distinguish the minor: by unity of union or composition, I grant; by unity of real identification, I deny. For subject and property are really identified; but matter and form are really distinct, although together they make one per se, which is the composite.

XCVII. Objection IV. If matter could exist without form, it would belong to some species, because nothing exists in the nature of things that is not placed under some species. But matter participates in no species, since the specific character is derived from form, which gives specific and essential being. Therefore it must rather be said that matter can participate in no existence without form. I grant the major. I distinguish the minor: matter does not obtain a complete and total physical specific character, I grant; an incomplete and metaphysical one, I deny. Thus the rational soul is said to be of a different species from the vegetative and sensitive soul. Likewise, Angels, though they lack a physical form, nonetheless differ in species and others in number, as I said (*tract. de Angelis, disputa. 1.*) I add that in the Thomist school, sublunary matter is of a different species from celestial matter. Therefore nothing is inferred in this objection that tells against us.

Article IX. Whether Matter Separated from Form Needs a New Being and Influx in Order to Exist and Be Conserved

XCVIII. The prior opinion is that of Henry (*Quol. 1. quaestione 10.*) and the Conimbricenses, (*1. Phys. capit. 9. quaestione 6. artic. 3.*) who think that matter separated from form, in order to exist as such, would need a new being and a special assistance. St. Thomas seems to favor them (*4. distinctione 12. quaestione 1. in solutione 2. artic. Quaestiuncula 3.*) saying that for an accident in the Eucharist to exist without a subject, it requires a new being bestowed by God. He would perhaps say the same of matter, if it were to exist per se without form. The posterior opinion is that of Scotus (*in utroque opere Oxon. & Paris. 2. distinctione 12. quaestione 2. propè finem,*) Bassolius, Tartaret, and other Scotists (*ibidem,*) teaching that if matter were separated from all form, it would receive neither new being nor a special influx from God. Ruiz, (*1. Phys. quaestione 5. art. 1. num. 15.*) Hurtado, (*disp. 2. Sect. 9. §. 55.*) and Arriaga (*ibid. sect. 6. Subsect. 4.*) support this.

XCIX. Note I. Matter can be considered in three ways: first, as having its own proper essence and existence distinct from anything else; second, as receiving formal or specific being from the form with which it is united to constitute the whole; third, as conceived existing per se, separated from all form. It is in this last way that the present inquiry is conducted — whether in that state some new being or special influx would come to it that it did not previously possess.

C. Note II. From the Doctor in the passage just cited: that some being accrues to matter existing per se stripped of all form can be taken in two ways — positively and negatively. Positively: that some entity is newly attached to it — this sense Scotus rejects and Henry accepts. Negatively: that matter exists per se without form communicating anything to that matter, so that such being is equivalent to the negation of the aforesaid being communicated by form. In this sense, Scotus says, it can be admitted that separated matter has such being — that is, per se being negatively understood — which does not belong to matter existing in the composite. For in order for the composite to be one per se, it requires the union of matter and form, from which it is caused. The Doctor asserts the same (*4. distinctione 12. quaestione 6. §. Ad Argumenta.*) of separated quantity in the Eucharist — which has no positive mode of existing per se, but only a negative one, that is, not actually being in a subject, while God maintains and conserves it just as he maintained and conserved it when it rested on and inhered in a subject, as Bassolius explains excellently. (*in 4. cit. 9. 1. a. 3.*)

CI. Assertion: if matter were separated from all form, it would receive neither new being nor a special influx. This assertion is divided into two parts, as the Doctor presents it. (*passu nuper citat.*)

The first part is urged as follows: First, matter enjoys its own essence, existence, and partial subsistence distinct from form and everything else. Therefore if it were separated from form, it would retain the same preceding being without anything added to it. The antecedent I proved in what precedes. The consequence holds: the same being that it has when conjoined persists when separated. For no change occurs except from the state of conjunction to the state of separation, which does not take away its being or introduce a new one.

Second: the rational soul, when separated from the body, remains the same without receiving new being, since it enjoys an essence and existence that is distinct and independent of matter. Therefore the same must be asserted of matter, which is prior to form and less dependent on forms than the soul is, as Scotus states. (*2. citat. ad calcem quaestionis 2.*)

Third: to the accident in the Eucharist separated from a subject, no other being is communicated than what it had in the subject — as the Doctor proves effectively and subtly. (*in 4. praememorto, quaestione 1. §. Hic dicitur ante A.*) The same therefore must be affirmed of matter if it were to exist without form, since the reasoning is equal in both cases. Furthermore, the conservation of a thing is a continued action of the same kind, as will be said in the book on causes. If therefore matter were separated from form, it would be conserved by God in its being by his maintaining it in its being — just as if the sun were deprived of its light, since it is by its very nature prior to light, it would persist in its being with nothing newly added to it. Likewise, if flowers are removed from a plant, fruit from a tree, or clothing from a person, the person and the aforesaid things remain the same without any addition.

CII. The second part is proved as follows: First, that power or influx would be either created or uncreated. Not the latter, for it would be God, since nothing except God is uncreated. Nor the former, for it would be either substance or accident, since there is no intermediate between substance and accident. Not substance, since matter alone is supposed to exist per se. Nor accident, since an accident cannot sustain a substance such as matter. Therefore there would be no influx or power for conserving matter existing per se without form.

Second: a subject that passes from privation to habit is changed, since change means nothing other than such a transition. But with matter alone existing, no change would intervene — no generation, no augmentation, etc., as is evident. This can be illustrated by staves held together and sustained by a hand: if one is separated from the others and held and conserved by the same hand, it would exist per se without the others, with nothing added to it. Say the same of matter existing alone, removed from form.

Furthermore, it is the same action by which God conserves matter joined with form and separated from form, since it is the same terminus. For if there were a new action and a special influx, there would assuredly be a new terminus. Therefore, since the same matter persisting per se endures, it must be conceded that there is no new power and no special influx there.

CIII. Objection I against the first part of the assertion: an accident cannot exist separated from a subject unless a new being is attributed to it; therefore likewise matter cannot exist without form unless it receives a new being from God. The consequence holds by parity. The antecedent is proved: an accident existing in a subject derives its being from the subject itself, so that the being of accident is to be in a subject or to inhere in it; therefore, to exist without a subject, it requires new being. I deny the antecedent. To its proof I distinguish: accident derives being from the subject in such a way that its being coincides with the being of the subject — this I deny, because accident participates in its own proper being distinct from the subject, since being is divided into substance and accident (5. *Met.* 15.) and the members of a proper division do not coincide, as I noted in the Epitome. (*lib.* 2. *qu.* 7. *art.* 1.) Accident derives being from the subject, that is, is caused by the subject and actually or by aptitude inheres in it — this I grant. But when it is by divine power separated from a subject, as quantity in the Eucharist, it retains its own proper accidental being and is only deprived of actual inherence in a subject. This is not the positing of a new being but the negation of actual inherence in a subject — as the Doctor notes among others. (4. *citat.* §. *Ad argumenta. ante G.*)

One might say: an accident separated from a subject has being per se because it exists without a subject; therefore, existing in this way, it has this new being, which is to exist without a subject. I grant the antecedent. To the consequence I say that this is not new being but the preexisting being of the accident, which previously actually inhered, and afterward does not actually inhere in the state

of its separation. Therefore the separation of accident from subject is not a positive action toward the term of what is separated, but rather the cessation of its actual inherence in the subject — as Bassolius well observes. (*cit. in fin. art. 2.*)

CIV. Objection II. An integral part separated from an integral whole takes on a new character of wholeness — for example, if a part of water is separated from the whole mass of water, that part takes on a new character of totality. Likewise therefore an essential part, such as matter, if separated from form, receives a new being that it did not have before. I grant the antecedent and deny the consequence. The reason for the disparity is that an integral part is a complete being; therefore, separated from the other parts, it enjoys a positive mode of totality. But an essential part, being an incomplete being, is also incomplete when separated from its co-part. Therefore in that state it obtains only the negative mode of not existing together with its co-part.

CV. Objection III. A new miracle does not exist without a new action toward that in which it is wrought; and a new action requires a new terminus. Since therefore the separation of matter from form is a miraculous and supernatural action, it plainly follows that in matter separated from form there is something new. I deny the major. For sometimes a miracle is effected by the withdrawal of divine concurrence — as the fire of the Babylonian furnace, with God not concurring, neither burned nor consumed the three Hebrew children cast into it. (*Daniel. 3.*) The sun did not hasten to set against Gibeon. (*Josue 10.*) So in the matter under discussion: if God were not to conserve form, nor the whole, but only matter, then matter would stand and exist per se. From this only the negative mode previously explained in Note II is derived.

One might say: matter would then not have natural but supernatural being, since its natural being is to be united and joined with form. But in that state it would be disjoined from form; therefore it would participate in a new being which is supernatural. I say that, given the hypothesis, matter would indeed have natural being with respect to its substance, but not with respect to its mode — because it would possess a supernatural negative mode, since it would be neither united nor joined with form.

CVI. Objection IV against the second part of the assertion: by natural power matter cannot exist without form, because of the mutual requirement of both, as is clear from what was said above. Therefore, for it to subsist alone, supernatural power and a special concurrence of God are required. I grant the antecedent and deny the consequence. For by that very power and concurrence of God by which matter was conserved when joined with form, matter abstracted from all form would itself be conserved — although the mode would be a supernatural negative mode, as was explained above.

Article X. Whether Matter Is of the Essence of the Composite

CVII. Many among the ancients — such as Averroes (7. *Metaphysica*, co. 21.) and Ianduno (*ibidem quaestione 12*) — as well as among the moderns — such as Zabarella (1. *de natura caeli*, capit. 8.) and Ricius (*primo de elementis*) — hold that matter does not enter into the essence of the composite. Durandus (4. *distinctione 44. quaestione 1.*) asserts that common matter is contained in the essence of the common composite, but that singular matter is excluded from the essence of a singular composite. Scotus, however, (7. *Metaphysica*, *quaestione 16.*) Anthony of Andrés, (*ibidem, quaestionis 12. & 3. distinctione 22. quaestione unica, artic. 1.*) Richard, (2. *distinctione 12. quaestione 3.*) Alexander of Hales, (3. p. *quaestione 6.*) and Faber (*Theor. 28.*) assert that matter is an essential part of the composite, both universal and singular.

CVIII. Note I. Setting aside the various senses of matter and form adduced by Scotus and Bassolius (*ubi supra*,) form and matter are each taken in two ways. Since they are relatively opposed (2. *Phys. 7. 26.*) and one relative term is spoken of in as many ways as the other, (1. *Top. capit. 12.*) they consequently admit of the same senses. I begin with form, which is better known than matter and through which matter is known by us.

First, form is taken as the form of the whole, which is the total essence and nature of a thing, signified by an abstract name — as humanity is the form of the whole, or the total essence of a human being. And just as something white is white through whiteness, so a human being is human through humanity, which is its concrete name. Second, for the form of the part, which partially and principally concurs in causing and constituting the whole — as the rational soul is the form of the human being, through which the human being is constituted in the being of a human being and is distinguished from everything else that is not a human being. Similarly, matter is taken as the matter of the whole, which is that which has the form of the whole — for instance, a human being having humanity — and then as the matter of the part, which together with form constitutes the whole. It is about the latter that the present difficulty concerns: whether, namely, the matter of the part is contained in the essence of the composite or not. Furthermore, both form and matter taken in the second way are divided into the universal, which belongs to the whole in common, and the singular, which is adapted to the singular whole. Furthermore, individual difference is usually called matter, as Scotus and Bassolius observe from Aristotle, as will be cited below.

CIX. Note II. The name "quiddity" is not found expressly in Aristotle, but only "what it is" (7. *Metaphysicae*, T. 11.) and frequently elsewhere. This is sometimes taken only for form (2. *Phys. 28. & 5. Met. 2.*) and sometimes for the total essence and nature of a thing (1. *de anima 11. and 7. Metaphysicae 39.*) and (8. *eiusdem operis 15.*) Aristotle therefore appears to speak variously about the quiddity of a thing, as the texts cited indicate. Therefore no judgment should be made as to whether those who call only form the quiddity are more Peripatetic than those who also

call the total essence the quiddity, as Perera prefers (*lib. 6. capite 1.*) — since Aristotle's doctrine is not located in the multiple acceptance and diverse use of names, as is clear from rational philosophy, which some call entirely dialectic and others call only the part that treats of probable matters. I would say that quiddity, which derives from "what," is more common and more universal than form and total essence, and abstracts from them both — just as substance abstracts from primary and secondary, as I explained and proved in the Logic. (*libro 3. quaest. 4. art. 2.*)

CX. Note III. From Scotus (*loco praecit. §. Ad 1. arg. G.*) "corruptible" is taken in two ways: as corruptible by remote potency, and corruptible by proximate potency. Something is said to be corruptible by remote potency when it has within itself the principle of corruption, yet cannot pass to act unless it is first in proximate potency — just as something is said to be able to heat when it has the power to heat, yet cannot heat unless the obstacle is removed and the patient is brought close. So fire is corruptible and color is visible. (*2. animae Titul. 66.*) But something is corruptible in proximate potency when it has its own existence in the nature of things, with the patient aptly disposed and no impediment interposed — so fire existing with nothing impeding it is proximately corruptible.

From this the saying is easily understood and explained: (*7. Met. Titul. 22.*) "Matter is that by which a thing can be and not be, and all things composed of matter are generable and corruptible" — even though he had maintained in the same place that quiddity cannot be generated or corrupted. And (*8. Met. capite 2.*) he had premised that all parts of a definition are forms. For there he takes matter for the singular existing thing that is generated and corrupted and does not fall under definition; for form, however, he takes the thing in the universal, abstracting from existence, which is defined and known and is ingenerable and incorruptible objectively — as the Doctor follows out excellently. (*ubi supra.*)

CXI. Assertion I. Common matter is of the essence of the common composite. This is defended, besides Scotus and the others named above, by Avicenna. (*5. Met. capite 5.*) It is so evidently true that the opposite opinion now seems antiquated, obsolete, and abandoned. It is proved first from Aristotle, who (*2. Phys. Titul. 21. & 7. Met. 39.*) writes that it pertains to the natural philosopher to treat of matter, because the whole physical thing is constituted from matter and form as its intrinsic constitutive principles. Hence shortly before, he argues against those who removed matter from consideration, admitting only form, in treating of the nature of the whole material substance. Then (*8. Met. Titul. 6.*) he greatly commends those who in the definition of the whole include both matter and form. And he had already signaled this. (*1. animae, Tuul. 16.*) Again (*7. Met. Tuul. 24. & Titul. 33. 34.*) he establishes that matter and form are parts of the composite; but form is undoubtedly of the essence of the whole; therefore matter also is. Furthermore (*2. Phys. Titul. 28. & 5. Met. Titul. 2.*) matter is an

intrinsic cause of the composite, for it is defined there as that from which something existing within it comes to be. Moreover (7. *Met. Titul. 17.*) definition belongs to composites, and composites are essentially integrated from matter and form. Whence in the same place (*Titul. 34.*) he illustrates this by the analogy of a syllable, which is constituted from letters just as the whole is composed from matter and form.

Second: the essential whole differs from the integral whole in that the essential whole consists of parts essentially constituting it, whereas the integral whole is made of parts not belonging to its essence at all — such as hands, feet, and the other members that integrate the body of an animal. But the physical whole is an essential whole, as no one denies, constituted from matter and form as its essential parts, as is clear. (2. *animae*, 2. 8. *Met. 3.*) Matter therefore is one of its essential parts.

Third: what is placed per se in a definition in the nominative case enters into the essence of that thing, since a definition is a discourse declarative of the essence of a thing. But matter is placed in the definition of the whole, as is clear from the passages just cited, in which it is read that the whole is the third thing constituted from matter and form. Therefore matter is an essential part of the whole.

Fourth: natural and corporeal things differ from incorporeal and spiritual things in respect of matter. Therefore God and the Angels, who are incorporeal and spiritual, are called immaterial and pure spirits. But if matter were not contained in the essence of natural composites, these would not differ from those in respect of matter — since, with matter removed from them, they would still participate in their total essence. To imagine another essential difference is entirely arbitrary and vain, and repugnant to the common sense of all.

Fifth: if form were the total essence of the composite, the rational soul, which is the form of a human being, would be the total nature of the human being — namely, humanity. And so a dead human being, since the rational soul persists, which is immortal, would also be humanity; and since a human being is human through humanity, just as a wall is white through whiteness, it would follow that a human being does not die, since its nature, which is humanity, does not perish — consisting, according to the adversaries, solely in the rational soul. How false this is, no one fails to see except the obstinate and the contentious. Augustine adds: (3. *Ciuit. capite ult.*) "The soul is not the whole human being, but the better part; nor is the body the whole human being, but the inferior part."

Sixth: just as artifacts consist of matter and form as their two essential parts, so natural composites are composed from matter and form, on the authority of Aristotle (*cit. Titul. 26.*) Hence they are defined through matter and form. (8. *Met. Titul. 9.*) And the metaphysical composite is made of genus and difference, which are related as matter and form. Finally, to the sacraments matter and

form are assigned as their essential parts, as Scotus teaches among others. (*4. distinctione 1. q. 2.*) Matter is therefore rightly numbered among the essential parts of the whole.

CXII. Assertion II. Singular matter enters into the essence of the singular composite. This is defended by the Doctor (*passu praealleg. sub. B.*) and proved as follows: First, from Aristotle (*7. Met. Titul. 36. 39.*) — just as the common whole is made of common matter and form, so the singular whole is made of this matter and form. But common matter is an essential part of the common whole; therefore singular matter is also an essential part of the singular whole.

Second: universal causes are productive of universal effects, and singular causes of singular effects. (*5. Met. capite 2.*) But this matter and this form are singular intrinsic causes — just as matter and form taken generally are universal intrinsic causes. Therefore just as from the latter a common composite is made, so from the former a singular composite is caused.

Third: in the predicamental series there are genera, species, and individuals. Those derive their constitutive and distinctive essential principles and causes from common and universal ones. Likewise, individuals participate in intrinsic and essential causes constitutive of them. And therefore, just as metaphysical composites are constituted from those causes and principles, so are physical composites. Since therefore the metaphysical individual consists of a singular nature contracted by the individual difference, consequently the physical singular is essentially constituted from this matter and this form. Finally, individuals of one species differ from one another in number because one is constituted from this matter and this form, and another from different matter and different form. I conclude therefore that singular matter is contained essentially in the essence of the singular whole.

CXIII. Objection I against Assertion I. Aristotle (*7. Met. Titul. 35.*) says: "The soul is the species, the account, and the what-it-is of the animated thing." But the soul is the form, and the quiddity and what-it-is: therefore according to Aristotle, matter is not of the quiddity of the whole. Confirmation I: From (*2. animae 8.*) and frequently elsewhere: form is what a thing is and what gives being to a thing. Confirmation II: From (*7. Met. 9.*) the composite from matter and form is to be set aside, because the substance of this is posterior to the quiddity of the thing — where the Stagirite expressly excludes matter from the essence and quiddity of the composite. Confirmation III: from the same book (*Tuul. 20*) — in things conceived without matter, quiddity and that which has quiddity are the same, as humanity and the human being who has humanity; but in things conceived with matter, quiddity and that which has quiddity differ. If therefore according to Aristotle matter is the cause why quiddity does not coincide with that which has quiddity, it is established in Aristotle's doctrine that matter is not an essential part of the material whole.

These must be handled and explained by a single distinction: form is the partial, principal, and completive quiddity — I grant; form is the total and complete quiddity — I deny. This explanation accords with the mind of the philosopher (7. *Met. Titul. 36.*) writing that the soul is not the animal but a part of the animal; and (2. *animae Titul. 10.*) he openly affirms that the soul and body are parts of the animal but not the animal itself, which arises from both together. This can also be confirmed by analogy with the ultimate metaphysical difference of a species, which is called its quiddity — not the total and complete quiddity, but the completive and constitutive one, just as rationality is the ultimate difference of the human being, but not the total one, since the human being essentially consists of animality and rationality. To Confirmations I and II the same is to be said. To Confirmation III: I say that that passage is to be interpreted as follows: in abstracts from singulars and individuals, essence and that which has essence are identified, because they are coextensive — humanity and human being extend equally, and the only difference is in the mode of signification: humanity is signified by an abstract name, and human being by a concrete name. But the singular is not coextensive with the universal, as this human being with the human being and humanity taken specifically, on account of the individual difference by which the common quiddity or nature is contracted and determined to singular and individual being. Therefore the instance at hand suffers from equivocation, taking the matter of the part for the individual difference, which Aristotle mentions. (1. *Caeli 9. 6. 12. Met. T. 49.*)

CXIV. Objection II. Matter is the principle by which a thing can be or not be — since privation is annexed to it and it is the cause of the corruption and generation of things. (7. *Metaphysica 22.*) But quiddity is necessary, eternal, and incorruptible, since it abstracts from all existence, by reason of which a thing is in proximate potency to generation or corruption, as I noted in Note III. Therefore matter is not a quidditatively part of the whole. Confirmation: quiddity pertains to the definition, which declares it. But matter does not pertain to the definition of the whole, since the parts of a definition are not material but formal. (7. *Met. 35.*) Therefore matter is to be removed from the quiddity of a material substance.

I respond by distinguishing the major: matter is the cause of generation and corruption with respect to its essence in the universal and in its quidditative being — this I deny, except remotely, as I explained at the passage just cited; with respect to existence and in the singular and in proximate potency — this I grant. For actions, such as generation and corruption, belong to singular existing things. Therefore, since matter in its essential quidditative being abstracts from existence and consequently from actual generation and corruption, it is not excluded from the quidditative character. The same response satisfies the confirmation: for the parts of a definition are called formal, that is, of the formal concept of the thing defined or definable. This does not exclude matter from the essence of the composite, since there form is not taken as it is distinguished

from matter, but for the essence and nature of what is defined, as I noted in the last note.

CXV. Objection III. What is not something, nor quantified, nor qualified, nor anything else is not of the essence of the composite. But matter is of this sort. (7. *Met.* 8.) Therefore matter does not pertain to the quiddity and essence of the whole. I grant the major. I distinguish the minor: matter is not a complete and total something — I grant; not an incomplete and partial something — I deny. For it is properly a substance, as is clear. (7. *Met.* *Tituul.* 9. 2. *animae* 2.)

CXVI. Objection IV. The human being and the brute differ essentially, being of different species — not in respect of the matter they participate in, since they are of the same species in sublunary and celestial things, as Scotus teaches (2. *distinctione* 14. *quaestione* 1.) — but in respect of form. Therefore the total quiddity of a thing is derived from form. I respond: even though the principal and specific difference is derived from form, the total difference is not — as Aristotle indicates. (12. *Met.* 27.) "Your matter is different from mine." Especially because the whole is a third thing really distinct from its parts and obtains a single total essential difference, by reason of which it is essentially distinguished from another specific whole. So a horse differs from a human being by irrationality and equinity, and the human being likewise differs from it by rationality and humanity.

CXVII. Objection V. What flows in and out of the composite is not its quiddity, which always persists as the same, since it is ingenerable and incorruptible. But matter flows through the continuous nutrition of an animal — for through it certain parts are lost and others acquired in their place, so that what is lost may be repaired and the animal restored. Therefore matter in no way contributes to the essence of the whole. Confirmation: the same matter can be informed by different forms, as is clear in those who eat human flesh. And in the Resurrection, the same matter in number, having been informed by different souls in the course of life, will be reassumed when those souls return to life.

I distinguish the major: what flows in and out entirely is not of the essence of the material substance — I grant; only partially — I deny. For the whole living thing persists throughout its life even though its parts are changed through continual nutrition. This is true not only of matter but also of material form, as will be proved elsewhere. All the more so because, even though this takes place in the singular and with respect to existence, it does not take place in the universal and with respect to essence, since actions belong to singular existing things.

To the confirmation I say that the same matter can be informed by different forms, not simultaneously but successively. It does not follow, however, that in the Resurrection the entire single matter in number will be under different souls at the same time. For even though it previously existed under them successively,

after the Resurrection it will belong to the first person whose soul informed it — as Scotus writes after Augustine (*in Ench. capite 85.*) (4. *distinctione 44. quaest. 1. §. de secundo O. & §. Ad argumenta L.*) giving the reason: through animation that matter is proper to the first human being; therefore, if it is appropriated by the subsequent person, it must be returned to the first, whose possession it previously was and whom it concerns before the subsequent one. Just as if a woman happens to have had two husbands, both still living, she shall leave the latter and cleave to the former.

Article XI. Whether the Matter of Sublunary Things Is One in Species

CXVIII. This difficulty in the present context is treated only of the matter of sublunary, that is, corruptible things. For the matter of the celestial orbs will be discussed when we treat of the heavens. There are two positions in this article. The first is that of Gandavensis (*primo Phys. quaestione vigesima quarta*) and Zimara (*Theor. 96.*) who think that the matter of all these lower things is one in number only. The second is defended by Scotus (*secundo distinctione decimaquarta, quaestione prima, §. Respondeo. Sub A. Et 3. distinctione vigesima secunda, quaestione unica, §. contra ista. B. Et 4. distinctione undecima, quaestione tertia, §. De secundo. H.*) Richard, (*2. distinctione duodecima, quaestione nona.*) Mayr, (*ibidem quaestione tertia.*) Bonet, (*primo Phys. capite tertio, §. Habetur autem*) Hurtado, (*disputas. Secunda sect. quinta.*) Arriaga (*ibidem sect. undecima, subsect. prima*) and Suárez (*disputar. decimatertia Metaphysicae, sect. quinta, numero octavo.*) who affirm that the matter of sublunary things is one by specific unity. Although the authors of this second opinion commonly hold that the matter of corruptible things participates in specific unity, they nevertheless dispute among themselves. For some — such as Canon (*primo Phys. quaestione nona, dub. sexto, prop. tertia*) and the Complutenses (*disputat. tertia, quaestione tertia, §. tertio*) — think that specific unity is negative. Others, however — such as Faber (*Theor. 27.*) and two of our more recent authors (*disputat. 2. quest. 4.*) — assert that the aforesaid unity is positive.

CXIX. Note I. Matter, which is called first and second in different respects, as was said in Note III at the end of Article I of this question, when considered in itself and absolutely can be one positively and negatively. What has an entity from which positive unity arises is said to be one positively — as a human being participates in the rational soul through which it is one thing positively. But what lacks such an entity and principle from which such positive unity proceeds is called one negatively. In this way, those who posit matter as devoid of all entitative and formal act hold that it is one in species negatively. This is illustrated as follows: just as God, having an infinite and immense essence, is everywhere positively — because he fills all things — so the universal is everywhere negatively, because it is not determined to any place but abstracts from all place. So if matter obtains a real actual specific entity from which a

specific unity can proceed, it will be deemed one in species positively; but if it lacks the aforesaid entity from which such unity cannot proceed, it will be considered one in species negatively.

CXX. Note II. Unity taken universally is divided into transcendental and predicamental. Transcendental unity belongs to every being, since unity is a property of being. (*quarto Metaphysica, Titulo tertio.*) In this way, what is a being is one by this unity. Predicamental unity belongs to what is located in one of the ten categories. It is threefold: (*quinto, Phys. Titulo trigesimo tertio*) unity in genus, in species, and in number — of which there is abundant treatment in the Logic. (*libro tertio quarto.*) A fourth is added, called unity of integrity and continuity, which belongs to things that are homogeneous — thus the whole water of the sea is one by unity of integrity; and if all the waters that are distant from the sea were gathered together in one place, they would be one by the aforesaid unity of integrity. And if the parts and portions of the integral whole are separated from one another, they obtain their own numerical unity and differ from one another in number. Furthermore, something is one by intrinsic unity — as this matter is numerically one through its haecceity, which contracts and determines it to singular being — or by extrinsic unity, so matter is called one extrinsically through the form received in it, by which it is actuated and specified.

Note III. Unity follows upon the entity of a thing. If a thing is incomplete and partial, its unity is likewise incomplete and partial. But if a thing is total and complete, its unity is total and complete. Since matter, as shown above, is a partial and imperfect substance, from it there consequently proceeds an imperfect and partial unity — just as its existence and subsistence are also partial and incomplete. The reason for this can be adduced: a property does not surpass the nature and quiddity from which it emanates in nobility and perfection — on the contrary, it is surpassed by the very essence itself, since it is foreign to and consequent upon that essence.

CXXII. Assertion I. The matter of sublunary things is one in species. So Scotus, (*ubi supra.*) It is proved first from Aristotle (*duodecimo Metaphysica, Titulo vigesimo sexto*): "Your matter is different from mine by universal reason the same." But your matter and mine are singular and numerically distinct, agreeing in specific character and in the quiddity of matter — just as Peter and Paul are two human beings numerically distinct, participating in the same nature specifically, which is humanity.

Second: matter is defined. (*1. Phys. 82.*) But a definition does not belong to singulars but to universals, (*7. Met. 53.*) and especially to species. (*ibidem Titulo 13.*) Therefore, since matter is defined, it follows that it participates in specific unity. The same is derived from (*1. de gener. 24. & 2. eiusdem operis.*)

Third: one and the same thing in number cannot simultaneously be in different and distant places. But if matter were one in number, it would be in multiple

distant places simultaneously. Therefore it is not one in number but in species. The major is clear: the same thing cannot be both undivided and divided from itself. The minor is admitted: the same matter in number would be simultaneously in Rome under the form of Peter and in Paris under the form of Francis, and so on. More strongly: if God were to remove and separate the form that is in Rome from the matter remaining there, and also to separate the form from the matter that is informed in Paris while the same matter persisted, it would be evidently established that the same matter in number occupies those distant and remote places. Again, the same matter in number would be informed by contrary forms — the form of fire and of water — and would simultaneously be in what is generated and in what is corrupted; natural transmutation would be eliminated, and other absurdities would follow that render the aforesaid opinion false and untenable, as Canon in the passage cited attests.

Furthermore, from this matter contracted with this form there arises this individual. (7. *Metaphysice* 39.) Therefore from matter and form in common there arises a composite that is one per se. But such a composite is specific — for instance, fire. Therefore just as specific fire has a specific form, so also it has specific matter. For (2. *Phys. capite* 2.) cause and effect are proportioned: if in genus, in genus; if in number, in number. And if what is principled and composite differs, the principles must also differ — whether in genus, in species, or in number. But it is evident that sublunary composites differ in genus, or in species, or in number. Therefore their principles, among which is matter, obtain the same distinctions, differences, or unities.

Finally, just as from this and that form the specific character and quiddity of form is abstracted, so from this and that matter the specific character and quiddity of matter is abstracted — common to individual and particular matters and predicable of them.

CXXIII. Assertion II. The specific unity of matter is not negative but positive. This is undoubtedly taught by the Doctor (*cit.*) following Aristotle (*ubi supra.*) It is urged first: from a real positive being there proceeds a positive property, as can be induced in all and each of the beings. But matter is a real positive being and of the essence of the whole, as I proved above. Therefore its specific unity is real and positive.

Malius, and with him the Complutenses (*praealleg. §. 3.*) respond, granting this of transcendental and analogical unity, but denying it of the categorical and specific unity of matter — which, being devoid of all positive act, consequently lacks positive specific unity. Against this: beyond the fact that this is said gratuitously, while the reasoning is equally clear for transcendental and predicamental unity — both entities are positive. Therefore from both a positive unity proceeds, especially because, from what has been proved, matter has entitative act, real positive existence and subsistence; therefore it also has real

positive unity. Again: form enjoys the aforesaid positive unity, even though it is drawn out from and depends on matter; therefore matter also enjoys the aforesaid unity. Furthermore, singular matter is one by positive unity through its haecceity; therefore its species also possesses positive unity — for if Peter is one by positive unity through Petrinity, the human being also, which is his species, is one by specific positive unity proceeding from humanity. Therefore, since matter is an incomplete species of material composite substance, and its individuals participate in positive numerical unity, positive specific unity is not to be denied to it.

Second: everything negative is reduced to something positive, as the adversaries do not deny. Therefore if specific negative unity is attributed to matter, such unity must be reduced to specific positive unity. It cannot be reduced to a subaltern or lowest species of body, because it does not regard any species unless it is informed by a form. Therefore matter does not lack positive specific unity.

The Complutenses respond (*praememorati, numero 37.*) that it is reduced to a positive species — not positively but negatively: that is, not as an imperfect positive species to a perfect one, but as a negative to a positive, negatively. The reason is that matter borrows its actuality and unity from form. Therefore matter taken in itself and nakedly has no positive unity.

Against this: matter is a partial and incomplete substance, referring to the composite of which it is a positive essential part. But a positive part is reduced to a positive whole. Therefore matter is reduced to a complete positive species not negatively but positively. Again, matter is located in the category of substance reductively as I noted in the Logic (*libro 3. quaest. 3. articulo 4.*) — because it is a part of a complete species, since from it, per se, together with form, the natural body coalesces, which is one per se and a complete substance. But an imperfect positive being is reduced to a perfect positive being; therefore, since matter is an imperfect positive being, it is reduced positively to a perfect positive being, and consequently its unity is positively specific.

CXXIV. Objection I. Aristotle (*1. Phys. 60. & 66. ac 2. Met. capite 2.*) writes that matter is one numerical subject of the transmutations of natural things, remaining under each extreme — and such a subject is matter. Therefore according to Aristotle, matter is one in number. I respond by explaining the philosopher thus: matter is one subject numerically of forms simultaneously — this I deny; successively — this I grant. For this body, which is now the subject of the soul, after the death of the animal will be the subject of the form of a worm; and what is now under the form of water will afterward be under the form of fire. Therefore this matter in number is, over the course of time, subject to many and diverse forms.

One might say: matter and privation are one in number; therefore not only successively but even simultaneously is matter one in number. I say that this is to be one in number by the unity of the subject and extrinsic unity, not intrinsic unity — which is what we are speaking of in the present context.

CXXV. Objection II. If matter were deprived of all form and all its portions existing in the world were gathered together into one, they would be one in number. Therefore, even though it is now found in many distant places, it does not depart from numerical unity. Confirmation I: matter is the terminus of creation, which regards the singular. Confirmation II: what is one in species is predicated in the "what" of its individuals. But matter is not predicated of singulars in the "what" — both because it is not a "what" (*7. Met. 7. 8.*) and because singulars presuppose species and presuppose genus; but no genus can be assigned that belongs to matter.

I respond: given the hypothesis, matter would be one by unity of integrity and continuity, not however by numerical unity, as was explained above in the case of the sea. To Confirmation I: I say that the immediate terminus of creation is singular, and the mediate terminus is universal — which also holds in other created things. For a human being is said to be the terminus of creation, even though this particular human being is immediately created and the human being mediate. To Confirmation II: I say that matter is not a total but a partial "what," less principal, and it is a part of the species, reducible to the genus of substance.

CXXVI. Objection III. If things principled differ from one another in genus, or species, or number, the principles also differ according to genus, species, or number. (*12. Met. 27.*) And the same is premised (*5. Me. cap. 2. T. 3.*) Things principled, or composites, differ from one another some in genus, some in species, and others in number. Therefore the same must be asserted of matter — especially because matter concurs toward the essential constitution of composites just as form does. And form and composites from both obtain the aforesaid unities and differences. Therefore matter does too. All the more so because matter derives its being from form; therefore just as form is one in genus, or species, or number, so also is matter.

I respond that those passages are to be interpreted of second matter, which, being disposed with various and diverse dispositions fitting and proximate for receiving various and diverse forms, and clothed with them, participates in those unities or differences. Therefore it does not receive those aforesaid unities intrinsically but extrinsically — that is, from form and the composite that coalesces from them.

One might say: those cited testimonies of the philosopher, brought forward in the preceding assertions to prove the specific unity of matter, introduce not only specific but also numerical unity. I say that through them is proved the intrinsic

unity of prime matter taken nakedly, and the generic extrinsic unity of second matter taken with the proximate and due dispositions mentioned. Therefore they do not tell against the preceding assertions.

Article XII. On the Potency of Matter

CXXVII. That matter is in potency to receiving form and to causing and constituting the composite seems to present no difficulty. The question is, however, what kind of potency this is and how many kinds it has, and whether it extends to every form — all of which I shall decide and settle through the following disputations.

Dubitation I. Whether Potency Is of the Essence of Matter

CXXVIII. I find three divergent philosophical positions. The first is that of Themistius, (*1. Phys. digreff. ult.*) Averroes (*ibid. com. 69.*) and Ianduno (*quaest. 25.*) who think that the potency of matter is an accident superadded and adventitious to it, of the genus of quality. The second is that of St. Thomas, (*1. Phys. T. 79. 1. P. quest. 115, a. 1. ad. 2.*) and his disciples, to whom are joined Ruiz, (*Tract. 1. de materia, quest. 6.*) Hurtado (*disp. 2. quaest. 2.*) and others, who affirm that the potency of matter entirely coincides with its essence. The third is defended by the Doctor, (*2. d. 12. quaest. 1.*) Mayr, (*ibid. quest. 4.*) the Parisian school, (*1. Phys. quest. 3. fol. 29.*) Canon, (*quaest. 9. dub. 5.*) and John of Magistris, (*quaest. 12. dub. 1.*) who assert that the potency of matter is formally distinct from it.

CXXIX. Note. From Scotus (*4. d. 43. quest. 3. §. Quantum ad istum art. H.*) the potency of matter is twofold: fundamental and formal. Formal potency is the relation of potentiality of matter really inhering in it, through which matter itself is formally said to be able to receive form. Fundamental potency is the potential principle or root of potentiality, from which formal potency emanates — just as risibility proceeds from humanity. Formal potency is subdivided into actual and aptitudinal: actual, by which matter is said to be actually able to receive form; aptitudinal, by which matter is said to be able to receive form by aptitude. Furthermore, it is divided into proximate and remote. Proximate is that by which matter exists disposed by the fitting and due dispositions for receiving this or that form. Remote is that by which the same matter is taken nakedly, without any dispositions, for receiving any form whatsoever. The former is called particular; the latter universal. Nor is the division of potency into receptive — by which matter receives form — and causative — by which matter itself partially causes the composite — to be despised. And perhaps the subdivision into receptive and sustentative will not be useless: since matter receives any form whatsoever, but is said to sustain the irrational and not the rational.

CXXX. Assertion I. The fundamental potency of matter is of its essence. The Doctor holds this. (*ubi supra.*) It is proved first from Aristotle: (*2. animae 2.*)

"Matter is potency, but form is act." Therefore, according to Aristotle, just as form is essentially act, so matter taken fundamentally is essentially potency. And in (8. *Met.*) the philosopher, (7. 15.) investigating why from matter and form there arises one per se thing, gives the reason: because matter is per se potency and form is per se act. And in the same book (*Titul. 3. & 5.*) he had premised that there are two essential parts of a material composite substance, one of which is potency or matter and the other is act, namely form.

Second: what is placed in the nominative case in the definition of a thing is of its essence, since a definition is the declarative instrument of the essence of a thing. But potency is placed in the nominative in the definition of matter, as is clear from the passage just cited and from (1. *Phys. capite 9. Titul. 82.*) where in defining matter he says it is the receptive subject of form — which is the same as saying that it is a potency capable of receiving form, as all the interpreters explain. Hence it is rightly named by Scotus and others "subjective potency" — just as the human being is called rational.

CXXXI. Assertion II. The formal potency of matter does not enter into its essence, but follows as its property. The Doctor patronizes this. (*citat.*) It is proved first: the formal potency of any subject is a potency and power, since it is said of the subject in the second mode of per se predication and is its property. Therefore, since the formal potency of matter is of this kind, it is not of its essence.

Second: what proceeds from the root and foundation of something does not participate in its essence, since root and foundation are presupposed and prerequisite to those things that arise from and follow upon it. But the formal potency of matter emanates from matter itself as from its root and foundation — as neighability from equinity and risibility from humanity.

Furthermore, relation does not enter into the essence of an absolute being, since being is equally divided into absolute and relative. But formal potency is a transcendental relation of the receptive to the received, from Scotus. (*in 4. distinctione 43. quaest. 3. ante 1.*) Therefore formal potency is not of the essence of matter, which is an absolute being, but is formally distinct from it as its property — as the Doctor teaches of every property. (*2. distinctione 16. quaest. unic. D. contra, quia. G.*)

Finally, the aforesaid potency is an inclination, aptitude, and capacity for receiving form — which plainly presupposes matter, whose inclination and aptitude it is. Therefore it is not essentially identified with it, but only really, as Scotus attests. (*4. dist. 49. quaest. 10. A.*)

CXXXII. Assertion III. The actual potency of matter is an accident separable from it. This is defended by the Doctor. (*4. distinctione 43. quest. 3. 1. §. Quantum ad istum.*) It is urged first: accident is defined as what is present and absent without the corruption of the subject, from Porphyry. (*in Isag. c. de accidente.*) But

actual potency is present and absent without the corruption of matter. For with matter remaining the same, the prior and preceding forms cease to be with their dispositions, and new subsequent forms arrive with their proximate and due qualities — as daily experience teaches us in the perpetual generation and corruption of sublunary things. Therefore the actual potency of matter is an accident of it.

Second: by divine power matter can be separated and exist without form and its qualities. Given that hypothesis, matter would be without the actual potency and union with form. Therefore the aforesaid potency is an accident located in the category of quality, as the Parisian school notes among others. (*praecit.*)

CXXXIII. Objection I. If potency were essentially or really identified with matter, potency would remain with matter remaining, and with matter ceasing so would potency cease. But potency persists while ceasing — since, when form arrives and informs matter, there is no longer potency in matter for that form; otherwise, with the form remaining, it could receive it again, and so could have it twice simultaneously, which is impossible. Moreover, the appetite of matter is for something not had; therefore once form is had, that appetite and desire for having it cease. But since the appetite of matter and its potency seem to coincide, if appetite ceases, then potency also ceases to be in matter with the arrival of new form, and therefore potency is neither essentially nor really identified with matter.

I grant the major and distinguish the minor: with respect to proximate and actual potency — I grant; with respect to remote, fundamental, and aptitudinal potency — I deny. For when a human being laughs, it has the potency to laugh, and when it runs, it has the potency to run — as Aristotle rightly argues against the Megarians (9. *Met. cap. 3.*) who denied that act and potency coexist. Therefore, when an agent exercises its operation it does not lose the potency to exercise it — on the contrary, it then most of all has it, because it brings it to act and conjoins it with act. To what is added about appetite: I say that even when form arrives, the appetite of desire ceases in matter, but not the appetite of complacency. Nor do I think that appetite coincides with the potency of matter, since the potency of matter is receptive of form and partially causative of the composite — which cannot be said of appetite.

CXXXIV. Objection II. Formal potency is a relation, as the Doctor concedes (*in 4. citat.*) For it regards a terminus and is directed toward it, by which it is specified. But matter is a substance and an essential part of the substantial whole. (8. *Met. Titul. 3.*) Therefore, since relation is an accident, it is not really identified with matter — otherwise form would be received in matter by means of an accident, namely its formal potency, and a per accidens one would be made, which is false.

I respond that formal potency is not a predicamental but a transcendental relation, really identified with matter — and is a proper accident, not a common one, about which the difficulty concerns. Therefore it does not follow that a per accidens one is made — just as from the soul and its faculties, really identified with it, when united to the body, there is no union by means of an accident, nor from the soul and the organic body is there made a per accidens one. But from a common accident really distinct from its subject, when they are joined together, there results from them a per accidens one.

CXXXV. Objection III. Formal potency is a predicamental accident: for potency and natural impotency are placed in the second species of quality. Therefore formal potency is not a property of matter nor really identified with it. I deny the antecedent. For as the Doctor writes, (*2. distinctione 16. quest. unit. in fine,*) in the second species of quality there resides not the principle of operating but the ease or difficulty of operating.

Dubitation II. How Many Kinds of Potency Matter Has

CXXXVI. Those who posit one matter in number for all sublunary things, as I recounted in Article XI of this question, consequently think there is one potency in number for receiving all forms. But those who teach that matter is one in species attribute to it one aptitudinal and universal potency, and hold that however many forms there are to be received in matter in number, there are that many proximate and particular potencies for receiving each of those forms.

CXXXVII. Assertion I. There is in matter a remote and universal potency indiscriminately regarding all forms. This is the position of Scotus, (*4. distinctione 43. q. 30. 1. & ibid in Report. quaest. 4.*) as he had demonstrated (*4. dist. 1. quaest. 1. ad finem.*) Vigerius, Orbellus, Lychetus (*ibid.*) the Parisian school, (*1. Phys. quaest. 3. fol. 20.*) John of Magistris (*ibid. quaest. 12. dub. 1.*) Tartaret (*quest. 7. dub. 3.*) and Canon. (*9. 9. dub. 1. in solutione diff. 2.*)

It is proved first from Aristotle (*1. Phys. cap. 9. Titul. 82.*) who, in defining matter, says it is "one and the first subject of all forms." But it is not one in number, because a definition does not belong to singulars; therefore it is one in species — which is capable of receiving all forms. But such capacity is its universal potency. Again, in (*7. Met. Tuul. 8.*) describing the same matter he says it is an indifferent and indeterminate subject for receiving any form whatsoever; therefore, since it does not of itself incline more to one than to another, it is clearly deduced that its potency is universal. The same is suggested in (*12. Met. 27.*) where he adds that there are singular matters to which one common and universal character of matter belongs, from which proceeds aptitudinal potency toward all forms, indifferent and indeterminate.

Second: as the entity is, so is its property — for property arises from entity, as is clear from being, whose property is unity. But the entity of matter is common

and universal since it is one in species; therefore its property, which is the receptive potency of forms, is one, universal, and common.

Third: the inclination of a thing follows upon the thing whose inclination it is — as the inclination toward the place above follows fire, and the propensity toward the place below follows earth. But there is one universal inclination of fire toward the upper place and of earth toward the lower place. Therefore likewise there is one inclination, capacity, and passive potency of matter toward all forms. Therefore just as there is in the human being one aptitude for laughing, in the horse one aptitude for neighing, and so on — so in matter there is contained one aptitudinal potency toward all forms.

CXXXVIII. Assertion II. As many proximate potencies in number are adapted to matter as there are forms receivable in number in it. The Doctor favors this along with his disciples (*ubi supra* & *in Rep. 2. distinctione 12. quaest. 1.*) and nearly all outside his school subscribe to this. It is urged first from (*12. Met. passu proxime alleg.:*) "Your matter is different from mine." But these singular matters obtain their singular properties — as this human being this risibility and this horse this neighability. And this matter, which is now under the form of a human being, has the potency of existing under the form of a worm; and what is under the form of a worm can be under the form of earth; and so on. Therefore corresponding to the multitude of forms, the potencies of matter are enumerated — and more explicitly (*3. Physicae 10.*) the capacity to be healthy and the capacity to be sick differ, just as being healthy and being sick differ, as Scotus notes. (*in Rep. cit.*)

Second: there are as many potencies in number in matter as there are natural tendencies of matter toward the reception of forms, because potency formally means nothing other than the respect and relation of the receptive to the received, on the authority of Scotus. (*in 4. cit. infra H.*) But its natural tendencies are multiplied according to the multiplication of forms — for each thing tends and is directed toward its perfection and complement. Furthermore, relation is multiplied according to the multiplication of termini in one numerical foundation. But the potency that is founded in matter is terminated at form, by which it is specified, determined, and actuated. Furthermore, in the same matter there are as many appetites as there are forms receivable in it through which it is perfectible. Again, one species regards all its individuals and singulars, one intellect all intelligibles, and one sense all sensibles. Therefore one matter is affected by as many potencies in number as there are forms receivable in it.

CXXXIX. Objection I against Assertion I. Act and potency are of the same genus. (*9. Metaphysica Tituul. 7.*) But act is form and potency is matter. Therefore, since form is manifold in genus and species, the same must be asserted of matter; and therefore there is not one remote and aptitudinal potency of matter. I respond by interpreting the major: of objective potency, about which the discussion is in

the present context — I deny. So the Doctor explains. (2. *distinctione* 12. *quaestione* 1. §. *positio ista*. A. Et 4. *distinctione* 11. *quaestione* 3. §. *Alii concedentes ante X.*) And he gives the example (*in Report. 2. definitione cit.*) of whiteness, which is the same actually existing thing that was previously in potency of the agent.

CXL. Objection II. Relations are multiplied corresponding to the multiplication of termini, on the authority of Scotus. (3. *distinctione* 8. *quaestione unica.*) But the potency of matter is formally a relation, from what was asserted above, and its formal terminus is form. Therefore, since there are many forms differing in genus and species, there are likewise many potencies of matter differing in genus and species; and therefore the remote and aptitudinal potency of matter is not one. I respond that the argument concludes about extrinsic, not intrinsic, unity and multiplicity — which is what we are speaking of. So one intellect regards intelligibles differing in genus and species, one common sense many sensibles far distant from one another, and one sight very many visibles greatly differing from one another. Therefore it is not inconvenient for one aptitudinal potency of matter to be directed toward many forms differing both in genus and in species.

CXLI. Objection III. The actual potency of matter is nothing, as the Doctor attests. (2. *Rep. distinctione* 1. *quaestione* 7. *propre finem*. Et 4. *Oxon. distinctione* 43. *quaestione* 3. K.) Tartaret gives the reason for this (*ad calcem* 2. *Phys.*): such potency perishes when its terminus — namely form — is posited, as Averroes writes. (1. *Phys. com.* 70.) But relation, with its terminus and foundation remaining, also remains, since it emerges from both. If therefore actual potency is nothing, it follows likewise that there is no numerical multiplication of it corresponding to the numerical multiplication of forms.

I respond that the said potency is nothing positive, if viewed as preceding form — for in that case it is the privation of form, which perishes when form arrives and its privation, signified by such potency, ceases to be. So the Doctor handles this (*in 4. cit. I.*) followed by Tartaret (*ubi supra*) and Toledo. (*quaestione* 12. *ad 1.*) But actual potency taken together with the actual capacity of matter for this or that form actuating and informing it is something real and positive — as the potency of laughing in Peter and the potency of neighing in Bucephalus.

One might say: if the aforesaid response is true, the potencies of matter would be multiplied to the multiplication of privations, and there would be as many potencies as privations. I say this is not inconvenient — not because form designates privation formally, but only connotatively. All the more so because form cannot be drawn out from the potency of matter unless privation precedes in matter. For the terminus a quo of natural generation is privation. Therefore, in order to acquire the partial principal terminus ad quem, which is form, it is necessary to proceed from privation to form.

CXLII. Objection IV. If matter regarded all future and possible forms, which are nearly infinite, it would be of infinite capacity. But infinity involves the greatest perfection, which is not fitting for matter, which is the least among substances. Therefore it does not seem to involve order and relation toward all forms. I distinguish the major: of active capacity and potency — I grant; of passive capacity and potency, which is the potency of matter — I deny. This response is derived from the Doctor. (*3. distinctione 14. quest. vn. ad finem.*)

Dubitation III. To What Forms the Potency of Matter Extends

CXLIII. That the potency of matter regards all present, future, and possible forms, all philosophers agree. They disagree, however, about forms that are past, already lost and destroyed. For many — among whom is Arriaga (*disputatione 2. Physica sect. 4.*) — deny that matter has any potency toward a form that has been corrupted and already destroyed. On the other side, Scotus (*4. distinctione 43. questione 3.*) Bassolius, Tartaret, and other Scotists (*ibidem*) affirm that matter has potency toward a past and lost form. Hurtado, (*disputatione 2. Sect. 3.*) Ruiz, (*tractatu 1. de materia, questione 2. dubitatione 4.*) and Racon (*disp. 2. articulo 3. Sect. 1. memb. 3.*) adhere to them, and Aureolus (*2. distinctione 12. quaestione 1. articulo 5.*) and the Parisian school (*1. Phys. 9. 2. fol. 29.*) suggest the same.

CXLIV. Note I. In the opinion of those — among whom is Scotus, cited — who think that certain things can naturally be reproduced, there is, with respect to them, no difficulty about whether the potency of matter extends to past and lost forms. Whether this is true or not I will show and decide in the book on generation. But among those who deny that anything can be restored by natural power, the debate in the present context holds. Setting aside that negative position, then, the investigation is whether in matter there exists a potency and natural inclination toward a past form already once corrupted — about which two opposing positions cited above are recorded.

CXLV. Note II. That something cannot be effected in another can happen from two sources. First, intrinsically — if no capacity and inclination is found in it, as wood cannot see because in it no fitness and propensity for receiving sight is found. Second, extrinsically — if an obstacle intervenes or a natural agent cannot by its natural power introduce a form into a subject, as grace cannot be introduced into a human being by a human being, because grace is not in human but in divine power, according to the psalm: (*Psal. 85.*) "The Lord will give grace and glory."

CXLVI. Note III. Matter can be considered in three ways. In one way, as it is disposed with fitting and due dispositions for receiving form — in this way it is called proximate matter. In another way, with no congruous disposition or prior quality for the reception of form — in which way it is called remote matter. Third, insofar as it lacks both those qualities and there is no natural agent found

that can introduce or draw out form from it — in this sense it is called most remote matter.

Furthermore, it must not be omitted that receptive potency regards the agent and the form. If it regards the agent, it is called natural when the agent is natural and produces it in the usual manner, and supernatural when the agent is supernatural or produces it in an unusual way. But if it is considered in relation to form: either matter inclines toward it, and the potency is natural; or it is repelled, and the potency is violent; or it neither inclines nor resists receiving it, and the potency is neutral.

CXLVII. Assertion. The potency of matter extends also to forms that have been had and now lost. The Doctor defends this. (*4. distinctione 43. quaest. 3. H... K.*) It is proved first: the rational soul, which is the form of the human body, when separated from the body, naturally inclines toward informing the same body. But the human body is the matter of that soul. Therefore matter is receptive of past and corrupted forms. The major is from Augustine (*tum 12. de gen. ad litt. capite 35. tum etiam 22. Ciuit. capite 22.*) citing Virgil (*6. Aeneid.*): "And wishing once more to return into bodies." And Scotus (*Quol. 13. §. Ad argumentum principale. MM. Et 4. distinctione 49. quaest. 3. F.*) openly teaches that the rational soul separated from the body has a natural propensity by its own nature toward union with the body previously informed by it.

One might say, with Arriaga (*disp. 10. de anima sect. 2.*) that the soul naturally inclines toward reunion with the body not absolutely but conditionally — that is, if such a union were naturally possible. But it is naturally impossible, since no natural agent can effect it.

Against this: matter participates intrinsically and of itself in such a natural inclination, as Arriaga himself frankly admits there. But the fact that no created agent can achieve its reunion with the soul does not stand in the way. For no natural agent can attain the creation of the soul, since it is created and infused by God alone into a rightly organized body — toward which the body absolutely inclines. Again, a human being cannot produce grace and glory, which God alone bestows, and yet the Doctor shows that it has simply a passive and natural receptive potency for it. (*quaestione 1. Prol.*) All the more so because the question is not whether there is a natural agent that can reunite matter with a corrupted form, but whether a potency toward it exists in matter. Arriaga in the passage cited admits such potency in matter toward that form; therefore also the inclination, simply and absolutely.

Second: perfectible and incomplete matter tends of its own nature toward its perfection and complement. But form is its perfective and completive element — for it specifies and actuates matter. Therefore if matter loses the form that was perfecting it, it remains perfectible and incomplete as it was before receiving the form; and therefore it still has potency and inclination toward it.

One might say: toward the impossible there is no potency and no inclination. But a corrupted form is impossible, because no created power can restore and reconstitute it. Hence Aristotle in the *Logic* on opposites adds that from privation to habit there is no return. Therefore matter no longer inclines toward the lost form.

Against this: a destroyed form is not simply impossible, nor does it involve any contradiction that it be reproduced and restored by God — as the adversaries do not deny. But if God restores it, from it and matter joined together there arises one per se thing — for no other reason than that the one is act and the other is potency. Therefore, even though natural powers cannot achieve its reproduction, this does not remove from matter its natural potency toward receiving it again.

Third: the potency of matter is either its essence, as the Thomists think, or its property, as the Scotists think. By whichever you choose, it cannot be taken away from it; therefore matter still inclines toward the lost form.

One might say: the potency of matter formally includes the negation of the first production of form — since the corrupted form was already once produced; therefore the potency of matter no longer naturally tends toward it. Against this: the potency of matter means nothing other than the capacity to receive form. Therefore, without any authority or reason, it is imagined to formally include that negation in order to neutralize the force of the argument. For whether the form has not yet been produced or has already been produced, the potency for receiving it — if it be produced or reproduced — remains in matter. For if God reproduces the form and unites it to matter, matter will receive that form through its potency; therefore the negation in the potency of matter with respect to the production of form is futile and irrelevant, since with that removed matter always retains the aforesaid potency. This Arriaga seems to sense (*disp. 10. de anima cit.*) when he says that matter inclines of itself toward receiving the soul separated from the body.

Fourth: after the corruption of form, the privation of it remains in matter — just as after light there is privation of light in the air. Therefore matter is directed toward having it again. The antecedent is at hand, for privation is found only in a subject fitting and capable of receiving the form it lacks.

Arriaga responds by denying that there properly remains in matter a privation, appetite, or potency for recovering the form. Just as there is no potency for past time, so there is no potency of matter for a corrupted form. Against this first: the same author in the passage on the soul frankly admits that matter of itself enjoys a potency toward a form already had — as the body toward the soul — but now in the *Physics* he denies it. Then: matter is then properly deprived of form, just as it lacked it before receiving it — even if it cannot possess it again, the fault is not its own but that of the natural agent unable to reproduce it. Just

as the heavens are simply corruptible even though no created power can destroy them. Again: even though the past, as past, cannot be made so as not to have been past, yet what was past can be future again — toward which there is potency. So a lost form, even though it cannot be made so as not to have been lost, can nonetheless be future again — toward which there is potency and capacity in matter for receiving it again, and in form the capacity to inform it anew, as the Doctor not obscurely indicates. (*ubi supra.*)

CXLVIII. Objection I. To every natural active potency there corresponds a natural passive potency, as is derived from (5. *Met. Tuul. 17.*) where Aristotle describes passive potency through its relation to active potency. And (3. *animae 17.*) he urges that the soul has a passive intellect because an active intellect is adapted to it. Furthermore (2. *Caeli cap. 8.*) he adds that if nature had given the stars a progressive power, it would have given them instruments through which to exercise that power. But in the series of natural things there is no natural active potency for a destroyed form; therefore neither is there a passive potency for receiving it.

I respond that the major admits of counter-instances. For in the human body there is a passive potency for receiving the rational soul, but not an active potency, since it is produced and infused by God alone. Likewise in a blind person there is passive potency for sight, but not active potency. And in celestial matter there is passive potency for another form, but nonetheless no created active potency is given that can draw it out and destroy the preexisting one.

In order for that proposition to be universally true, it must be explained and distinguished with the Doctor: (4. *d. 49. quaest. 11. §. Ad argumenta. K. & dist. 43. quest. 3. Et quaest. 1. Prol. sub Q.*) in the series of created nature — I deny, as the instances brought forward make plain; in the whole coordination of created and uncreated being — I grant. For God, supremely sovereign over all, can produce and reproduce every form toward which passive potency is inclined. Therefore, even though that axiom is true in many created things, it is not true in all, unless it is explained in the way I now set out.

CXLIX. Objection II. Potency does not tend toward the impossible. But a destroyed form is impossible to be restored by a natural agent. Therefore no potency of matter exists toward it. I grant the major and distinguish the minor: by a created agent — I grant; by an uncreated agent — I deny.

One might say: that form would not be natural, as is supposed, but supernatural, because it would be effected by a supernatural agent. I say that it would be absolutely natural, because it would be received in a nature — matter — naturally inclined toward it; and relatively and extrinsically it would be supernatural, because it would be effected by God as a supernatural agent.

CL. Objection III. A relation does not exist unless its terminus, by which it is specified, exists. But the potency of matter is formally a relation, and the

corrupted form, which ought to be its terminus, does not exist. Therefore neither is the potency itself in matter for that form. I distinguish the major: a predicamental relation — I grant; a transcendental one — I deny, as is clear from what was said in the Logic. (*l. 3. q. 6. art. 11.*)

Article XIII. On the Appetite of Matter

Dubitation I. Whether Matter Desires Form

CLI. Avicenna (*1. sua sufficientia 2.*) and Justin Martyr (*in conf. dogmatum Aristotelis*) deny that matter desires form. Albertus seems to support them (*tractat. 3. cap. 17.*) saying that appetite is not in matter but in the one directing and moving it toward form. But Aristotle and his interpreters affirm it, (*1. Phys. Titul. 81.*) notably Scotus. (*1. distinctione 1. quaest. 1. ad finem. Et quaest. 10. quarti, d. 49. §. Respondeo sub 4.*)

CLII. Note I. Appetite proceeds from the nature that desires as its property, and taken universally is described as the inclination of a thing toward a good that is fitting and proportioned to it. Appetite is multiplied corresponding to the multiplicity of things and natures. Since one nature is devoid of cognition and another possesses it, from them is born a twofold appetite: natural and elicited. Natural appetite is the inclination of a nature toward a good fitting to it without any prior cognition — so the earth by natural appetite desires the place below and fire the place above. Elicited appetite is that by which a nature tends toward a good fitting to it with cognition of it preceding. Since nature that knows is twofold — sensitive and intellectual — its appetite is likewise twofold: sensitive, which is also called animal, and intellective, which is also called rational. The former is the natural tendency toward a fitting good with its cognition preceding — so a horse desires oats and an ox hay. The latter is the inclination and propensity of intellectual nature with intellectual knowledge antecedent toward its perfection — so a human being by will desires honor and an Angel felicity. All this the Doctor touches upon (*1. distinctione 1. quaest. 5. §. Ex his patet.*) and Gadius indicates. (*Quol. 13. fol. 182.*)

CLIII. Note II. These three things — appetite, desire, and joy — seem to be related and to differ as follows: appetite abstracts from what is present and what is future. Desire is only of an absent thing, as St. Bonaventure (*3. dist. 26. in expof. lit.*) and Scotus (*ibid. quaest. 31. quest. unic. §. Respondeo Sub E.*) teach after Augustine (*in Psal. 118.*) saying: "Desire is the longing for absent things." Joy or complacency is of a present and possessed thing, which one enjoys and possesses. The Doctor mentions this (*2. dist. 17. quest. unic.*) and Tartaret expresses it (*1. Phys. quaest. 7. not. 4.*) and the Parisian school decides. (*ibid. q. 2. fol. 29.*)

CLIV. Assertion I. Matter desires form by natural appetite. So Scotus (*4. distinctione 49. quaest. 10. §. Respondeo sub A.*) citing that saying of Aristotle (*1. Phys. capite 9. Titul. 81.*): "Matter desires form as the ugly desires the beautiful and the

female the male." It is urged first: every perfectible thing naturally desires its perfective principle. For each thing inclines toward a good fitting to it, as I explained in Note I. But matter is perfectible, being the lowest substance, lacking all adornment, signified by the formless and empty earth (*Gen. 1.*) as Lyra interprets. But form is perfective — since it determines, actuates, and specifies matter, and covers what is as it were naked and obscure with its garment, illuminates it with its splendor, and — as Plato signifies in the *Phaedrus* — adorns it. Therefore matter rightly desires form.

Second: everything beautiful and divine is most desired, as Plato testifies in the passage just cited. But form is something beautiful and divine, as the Stagirite concedes in the passage just cited. For it is a certain participation and likeness of divine being — since just as all being is from God, according to (*1. Caeli capite 9. Tit. 100.*) "from him being is derived, more clearly to some, more obscurely to others" — so from form there is being, according to the common saying: "Form gives being to a thing." Furthermore, a part desires union with its co-part, and an incomplete being desires its complement. But matter is a part of the whole, and form is its co-part, from which together the whole is constituted. And matter is very incomplete and imperfect, capable of being perfected and completed only by form — just as natural materials are adorned and illuminated by artificial forms, as Aristotle suggests. (*loco cit. T. 69.*) Therefore matter naturally desires form.

CLV. Assertion II. Matter indiscriminately desires all forms. So the Doctor. (*1. dist. 1. quest. 1. in fine. Et 2. dist. 18. quaest. unic. §. contra primum infra D.*) It is proved first: matter is defined (*1. Phys. Tit. 82.*) as the first subject of each and every one — that is, of form, as all Aristotle's interpreters explain there. Therefore, since matter has universal capacity and common inclination toward all and each of the forms, it follows that it regards and desires them indifferently.

Second: matter is of itself indifferent and indeterminate. For in this it differs from form, which determines and actuates it. But as the nature of a thing is, so is the potency and appetite corresponding to it, as I was explaining in Note I above. Therefore, since the essence of matter is by its very nature indifferent, its appetite toward forms is likewise indifferent.

Furthermore: every form is a perfection of matter — since matter is specified and actuated by any form; therefore it indifferently desires each one. Just as the material of artifacts does not regard the form of Mercury more than that of Jupiter or another, as the Stagirite indicates. (*1. Phys. T. 69.*)

CLVI. Assertion III. Matter desires with the appetite of desire the form it lacks. This is consistent with the Doctor (*4. d. 49. quaest. 4. ante D. Et 3. d. 31. quaest. vn. §. Respondeo. C.*) and inconsistent with Arriaga. (*disp. 2. Phys. sect. 4. subsect. 1.*) It is proved first from Aristotle (*cit. T. 81.*) where he explicitly says that matter desires

and longs for form. Second: desire is appetite for something not had, as I noted with Augustine and Scotus in Note II; but matter does not have many forms toward which it nonetheless inclines as toward its perfection and complement; therefore it desires them not with the appetite of complacency — which is of a present thing — but of desire, which is of a thing not had and absent.

Furthermore, natural desire is directed toward a fitting good, and good is what all things desire (*1. Eth. cap. 1.*) — but form not existing in matter is something good and beautiful for it, as is clear from Assertion I. Moreover: there are as many appetites of matter as there are forms receivable in it, as Scotus asserts. (*1. distinctione 1. quest. 1.*) But the appetite of matter for a form not yet received in it is not an appetite of complacency, since it does not possess it; therefore it is an appetite of desire — since there is no intermediate between the two recounted above.

One might say: the appetite of matter having and actually possessing one form is satisfied, so that it does not desire another form. For since matter is incomplete and is completed through form, enjoying one form actually, it does not want another. And therefore, since it always underlies some form, it does not desire form by appetite of desire.

Against this: matter actually participating in one form is not at all satisfied, nor is it extensively completed, unless there were a most perfect form containing all the others virtually — as the Doctor says (*in 1. citat. in solut. 4.*) For the same matter obtains another appetite toward another form, because its appetite is multiplied corresponding to the multiplication of forms receivable in it. And existing in one and the same form, there is in it also privation of another form, by reason of which it desires that other form as drawable out from it. Especially because a future and possible form is something good, which is coveted by matter lacking it.

CLVII. One might press: if matter having one form were to desire another, it would be desiring its own destruction — since it cannot obtain the future form without the present one being expelled, for two non-subordinated forms cannot simultaneously be in the same matter. I say this is per accidens, since two forms cannot simultaneously exist in one and the same matter in number on account of their simultaneous impossibility, as the Doctor touches upon (*2. distinctione 18. quaest. unic. D.*) after Aristotle. (*1. Phys. Titul. 81.*) Furthermore, concerning the identity or distinctness of appetite from matter, and its plurality, the same is to be said as was asserted of the potency of matter in the preceding article — with only the term "potency" changed to "appetite" — as Fuentes suggests. (*1. Phys. quaest. 2. dif. 3. art. 3.*)

CLVIII. Objection I against Assertion I. Appetite presupposes cognition of the thing desired, as Aristotle concedes. (*1. magnorum mor. cap. 12.*) But matter is devoid of all cognition, since it lacks soul and mind; therefore it also lacks

appetite. I respond that the major holds of elicited, animal, and rational appetite, as is derived from Aristotle's cited text — but not of innate and natural appetite, about which we are speaking here, with Scotus. (*1. d. 1. q. 5. in fine.*)

CLIX. Objection II. Matter either desires the form it has, or the form it does not have. Not the first, because no one desires what it holds and possesses. Not the second — otherwise it would be troubled and would be under that form violently. Therefore in no way does matter desire form. I respond that matter desires each form but with a different appetite: with the appetite of complacency it desires the form it actually participates in, and with the appetite of desire the form of which it is deprived. Nor does it follow that it is violently under the form by which it is informed, because it does not incline determinately toward the opposite form — which would be the case if it were there violently. Therefore, since matter of itself does not incline more toward one form than another, it follows that it regards all indifferently and naturally inclines toward them, as Scotus teaches. (*1. distinctione 1. quaestione 1. in solut. vult. Et 2. dist. 18. quaest. vnic. D.*)

CLX. Objection III. Natural appetite is the inclination of a thing toward a good fitting to it, as Scotus attests. (*1. dist. 1. in fine quaestionis 5.*) But if matter desired a form it does not have, its appetite would tend toward evil — namely, the corruption of the form it has, since it cannot enjoy the form it desires unless the form it possesses perishes. Therefore no appetite exists in matter.

I grant the major and distinguish the minor: per se — I deny; per accidens — I grant, as Scotus indicates (*in 2. mox alleg.*) For matter per se is directed toward the form to be induced or drawn out into it — and this good is connatural to it. But the cessation of the preexisting form happens to it because of an agent unable to introduce a new form without the prior form being corrupted.

Dubitation II. How Many Kinds of Appetite Matter Has

CLXI. Recent philosophers appear quite discordant in deciding this proposed difficulty. For some — among whom Sghemma is listed (*1. Phys. digreff. 5. quaest. 6.*) — think that the appetite of matter tends toward form in common and universal terms, but not in particular and singular terms. And there are those who assert that the appetite of matter is multiplied corresponding to the multiplication of forms, both in universal and in singular being. Fuentes seems to hold this position. (*1. Phys. q. 2. diff. 3. 4. 4.*) The common view of the moderns, however, is that there is one universal, specific, and indeterminate appetite of matter, regarding form in common and each form in particular.

CLXII. Note I. From John of Magistris (*1. Phys. quaest. 13. scibili 3. dif. 3.*) and the Parisian school (*quaest 1. fol. 28.*) there is a twofold appetite touched upon by Scotus (*1. d. 1. quaest. 1.*) and made explicit by Vigerius (*ibid.*): one aptitudinal and indeterminate; another actual, singular, and determinate. The first belongs to matter taken nakedly and specifically, as its property flowing from its essence,

really identified with it — just as the universal and remote potency of the same matter. The second is adapted to matter disposed with these or those dispositions for receiving proximately this or that form. This latter appetite is really distinct from matter, just as the proximate potency is really distinct from matter and can be separated from it, as Canon notes among others. (*1. Phys. q. 9. dub. 5.*)

CLXIII. Note II. From the Parisian school (*cit. quaest. 2.*) that matter by its appetite is directed toward form can be taken in two ways: adequately and inadequately. Matter adequately regards form taken generically as its complement and perfection connatural and adequate to it. It inadequately regards any particular form, through which together with it there is constituted one per se singular thing, which is the singular composite — just as the universal regards singulars and especially species, individuals, and the relative its correlative, as Aristotle suggests. (*2. Phys. 26.*)

CLXIV. Assertion. Matter by its universal appetite is directed toward form not only with respect to its generic and specific degree but also with respect to its singular and individual degree. This is derived from Scotus (*5. Met. quaest. 7. §. contra confirmationem. Et 1. d. 1. quest. 1. 4. 4. 6. Ad 1. principale. Et 4. distinctione 43. quest. 3. §. Quantum ad istum.*) The Parisian school holds this explicitly (*praealleg. quaest. 2.*) followed by Ruiz (*tract. 1. de materia, quaest. 7. dub. 1.*) and two of our more recent authors. (*disp. 2. quaest. 6. 4. 1.*)

It can be urged first from (*1. Phys. Tuul. 81.*): "Matter desires form as the ugly desires the beautiful." But the ugly desires the beautiful not only in common but also in particular — as a fruit, this beautiful fruit delightful to the eye and pleasing to the gaze. Therefore matter desires form and this form, which renders it beautiful and gracious.

Then (*ibid. Titul. 82.*) matter is defined as the first subject of each and every form; therefore its appetite is founded toward all and each of the forms and toward form in common as well as in particular. And (*2. Phys. Tuul. 26.*) matter is said to be of the genus of relatives and to tend toward form, and toward another form there is another matter — where it is signified that matter is ordered toward universal and particular form, as the Doctor well infers in the Metaphysics passage mentioned.

Second: the appetite of matter is directed toward form as its perfective and completive terminus, so that from both there arises one per se thing, which is the whole. But not only from matter and universal form does there arise one per se universal thing; from matter and particular form too there arises one per se particular thing — as from matter and the form of fire there comes fire, and from this matter and this form of fire there coalesces this fire. Therefore the appetite of matter regards common and particular form.

Third: appetite is given to matter so that it may be perfected and completed. But matter is perfected and completed not only by universal form but also by particular form — for the singular is more perfect than the universal, since beyond the perfection of the universal it includes its own proper perfection, and actions are terminated at it. (*1. Met. in procoem.*)

Fourth: a property is coextensive with its subject, whose property it is, and belongs to those things that participate in the subject — as risibility is adapted to the human being and to each of its singulars, since the human being and each human being is risible. But appetite toward form is a property of matter, just as its potency toward form, as I showed above. Therefore, since there is universal form and singular form, its appetite is directed toward both. I add that a relation regards an adequate and an inadequate terminus — as the relation of species regards the specific nature, which is its adequate terminus, and its singular, which is its inadequate terminus. Similarly the appetite of matter tends toward universal form as its adequate terminus and toward particular form as its inadequate terminus, as I noted in Note II. Moreover, matter is perfected by form with respect to specific and individual being; therefore its appetite is completed and satisfied by both the aforesaid forms.

CLXV. Objection I. The appetite of matter is not one but multiple; therefore matter does not desire universal and particular form by the same appetite. The antecedent is affirmed by the Doctor: (*1. d. 1 quaest. 1. ad 4.*) there are as many appetites of matter as there are forms receivable in it. And (*3. d. 8. quaest. un. §. contra*): in a subject there are several potencies for several forms — but the potency of matter seems to differ little or not at all from its appetite.

This must be handled: the aptitudinal appetite is one, just as the potency of laughing in the human being is one and the potency of neighing in the horse is one; but the actual appetite is multiple, corresponding to the multiplicity of dispositions — in this way Scotus is to be explained from the cited passage, as I noted and explained in Note I.

CLXVI. Objection II. If matter naturally desired a singular form, if it actually possessed that form, it would be under another form violently. But matter cannot be violently under a form; therefore it does not desire a singular form but only the universal. I deny the consequence of the major, because violence designates the resistance of the subject in which form is received. But matter underlying one form does not resist another form receivable in it — on the contrary it inclines toward it; therefore it does not remain in a state of violence, as the Doctor writes. (*1. d. 1. quaest. 1. in fine. Et 2. dist. 18. quest. vnic. D.*)

CLXVII. Objection III. The appetite of matter does not tend toward the impossible — otherwise it would be in vain. But if matter desired singular forms, its appetite would be directed toward the impossible, since some forms are mutually contrary and impossible. Therefore matter does not desire

individual and singular forms, but only common and universal ones. If the major is granted, the consequence of the minor is denied. For even though contrary forms cannot simultaneously exist in the same matter, they can do so successively — as is clear of contrary qualities, which do not simultaneously but successively affect the same subject. Therefore there is no opposition and impossibility on the part of matter, since it is of itself indifferent and indeterminate to receiving any forms. But on the part of the forms themselves, which are simultaneously incompatible and impossible in the same thing — as the Doctor excellently shows. (5. *Met. q. 7. §. pro solutione notandum.*)

Dubitation III. Whether the Appetite of Matter Is Equal toward All Forms

CLXVIII. The prior opinion is that of Toledo, (1. *Phys. quaest. 15. in fine,*) Arriaga, (*disp. 2. sect. 4. Subsect. 1.*) and Ruiz (*tract. 1. de materia queaest. 7. dub. 2.*) who think that matter desires all forms with equal appetite, both noble and ignoble. The posterior opinion is that of others, whose names Ruiz suppresses (*praecit.*) and which is strenuously defended by the twin Scotists (*disp. 2. quaest. 6. art. 2.*) and Pontius (*quaest. 7. de materia conc. 2.*) and others who think that matter desires forms unequally — that is, nobler forms more than ignoble ones.

CLXIX. Note I. Recall from Dubitation I of this article that appetite is twofold: innate and elicited. The innate is the inclination of the desiring potency toward its end and perfection without any elicited act — as Bassolius well shows. (4. *dist. 49. quaest. 6.*) The elicited is conjoined with an elicited act of the desiring potency — so the will by elicited act pursues what is good and fitting to it. The first always remains with the nature and potency whose appetite it is, since they are really identified and differ only formally. The second is sometimes present and sometimes absent — both because it is really distinct from the nature whose appetite it is, and because the desiring potency does not always elicit an act. Hence it comes about that the intellectual appetite, which is the will, always has a natural appetite consequent upon and concomitant with it, which means nothing other than the inclination of the will toward a good fitting to it, as Tartaret notes. (1. *Phys. quaest. 7. scibili 4. in fine.*)

CLXX. Note II. From Anthony of Andrés (1. *Met. q. 2. 9. Respondeo.*) there are many differences of natural, animal, and rational appetite. First, rational appetite is formally free; not so animal and natural appetite. Second, animal and rational appetite sometimes name a potency and sometimes an elicited act, whereas natural appetite names neither — because each thing of itself, without anything added to it, inclines toward its natural end. Third, natural appetite is wider than animal and rational appetite. For natural appetite belongs to all, both animate and inanimate; the others only to those that know and enjoy life. Fourth, the latter two presuppose a prior act of the knowing potency — as the will the act of the intellect, and sensitive appetite the act of the knowing potency — while the former presupposes no act of another potency; so heavy things desire the below and light things the above with no preceding act.

CLXXI. Note III. One form surpasses another in nobility with respect to specific difference and essential degree — as the form of fire is essentially more excellent than the form of earth, and the sensitive soul than the vegetative soul. And one surpasses another with respect to individual and perfective degree — as the soul of Christ the Lord is nobler than the soul of Judas. Therefore among forms one excels another, and among natures form excels matter — and form is more of a nature than matter. (2. *Phys. T.* 12.)

CLXXII. Assertion I. Matter more desires a nobler than an ignoble form. This is gathered from Scotus. (4. d. 49. *quaest.* 10. §. *Respondeo. B. & dist.* 50. *quaest.* 5.) It is proved first: a perfectible thing desires perfection; what is more perfectible desires greater perfection; and what is most perfectible desires the greatest perfection — as Scotus argues from Aristotle (1. *Met. in initio*,) (*ibidem*,) explaining that saying: "All human beings by nature desire knowledge." If every human being by his own nature desires knowledge, he most desires the greatest knowledge. But metaphysics is the greatest knowledge, being the queen of the sciences and the apex of learning. Therefore he most desires it.

Given this, I argue by analogy: matter desires form as the ugly desires the beautiful and the imperfect desires the perfect. (1. *Phys. T.* 81.) Therefore matter more desires a nobler form as its greater perfection than an ignoble one, which is a lesser perfection. The consequence holds, because nature per se tends toward what is better and more perfect. (2. *de gener. T.* 59.)

Second: what more perfects, completes, and satisfies the appetite of matter is more desired by matter — because, since natural appetite is the capacity and inclination toward a fitting good, a greater and more perfect good more satisfies and terminates its tendency. Hence the Doctor adds (1. d. 1. *quaest.* 1. ad 4.) that if there were a most perfect form containing the other forms virtually — as the rational soul contains the sensitive and vegetative — it would completely and fully satisfy the appetite of matter. Therefore if the most perfect form perfects the most, the more perfect form will more perfect and satisfy the appetite of matter than the less perfect.

Third: matter desires form in order that there may be one per se thing and one perfect thing, which is the composite, as the philosopher indicates. (1. *Phys. Titul.* 80.) But from a nobler form there is constituted a nobler and more perfect whole. Therefore matter more desires a nobler form than an ignoble one.

Fourth: matter more desires substantial form than accidental form, as even the adversaries grant — for no other reason than that substantial form is more excellent than accidental. Therefore among substantial forms, the one that is nobler and more perfect is more desired by matter.

Nor does it help to say with Pontius (*citat.*) that matter desires substantial form not precisely because it is more perfect but because through it accidental form is acquired. For in the opinion of the adversaries who assert that matter

immediately receives accidents, matter does not receive substantial form on account of accidental form, but rather the contrary. Then, matter is not perfected by accidental form except in a qualified sense — especially because the proper subject of accidental form is the composite, and from it and the subject there arises only a per accidens one. I add that nature acts for an end (2. *Phys. T. 75.*) — but the principal end of matter is not accidental but substantial form. Therefore matter as recipient is not recipient of substantial form on account of accidental form.

Fifth: elicited appetite tends toward the greater good; therefore natural appetite also tends toward the more perfect good, which is the more perfect and excellent form. The antecedent is clear. (2. *Phys. T. 76. 78.*) Nature per se intends what is better, more fitting, and more perfect.

One might say with Pontius (*ubi supra*) that there is a disparity between elicited or free appetite and natural appetite — since an agent with elicited appetite acts by choice and by discerning one good from another and preferring the nobler and more perfect to the ignoble and less perfect. But the natural appetite of matter, without any prior cognition and discrimination of one good from another, inclines toward form; therefore it equally desires both the noble and the ignoble.

Against this: freedom, which belongs to elicited and free appetite as it is distinguished from natural appetite, is not the cause of the former tending toward a greater good. For sometimes the will by its own pleasure chooses a lesser good — or even evil — as I showed in the Moral Philosophy. (*quest. 3. art. 3. 1. 2.*) The parity holds in this: just as elicited appetite most often tends more toward the greater good, so natural appetite inclines toward the more perfect and more fitting good. Hence Scotus (*in 4. dist. 49. cit.*) asserts that the will by innate appetite inclines toward beatitude, which is its greatest perfection. Therefore judgment and discernment toward greater or lesser good bear extrinsically and impertinently on the matter. All the more because appetite taken precisely is a natural tendency toward a fitting good; therefore toward a greater and more fitting good there is a greater tendency — with any discernment and judgment whatsoever set aside. So a heavier weight rushes toward the center with greater speed and more rapid impetus, as experience shows.

CLXXIII. Assertion II. Matter having a nobler form also desires to be under an ignoble form. This is derived from the Doctor (*in 1. nuper alleg.*) who teaches that in matter there are as many appetites as there are forms receivable in it. It is urged first: each thing desires its own perfection, as I have repeatedly emphasized. But an ignoble form is a perfection of matter, because from this and that there arises one perfect thing, namely the composite. Therefore matter informed by a noble form desires an ignoble form.

Second: appetite is the same as the fitting capacity to receive a form not had. But matter existing under a more excellent form has such a capacity, since it is the receptive subject of all forms. (1. *Phys.* 82.) Therefore, thus existing, it desires a less excellent form.

Third: unless matter participating in a superior form were to desire an inferior one, the perennial generation and corruption of sublunary things would cease, and the whole constituted from matter and the more excellent form would be perpetual, and those that possess the lowest and deepest forms would utterly perish — whereas we experience the continuous generation and corruption of things; but Aristotle testifies that such birth and death arise from the appetite of matter. (9. *Met.* 17. & *premised* 7. *eiusdem operis* 22.)

CLXXIV. Assertion III. If matter enjoyed the most perfect form virtually containing all other forms, the appetite of matter would be terminated. Scotus expressly holds this (*passu proxime cit.*) against Pontius (*ubi supra conclus. 3.*) — preceded by our more recent authors mentioned at the end. It is proved first: the reason matter existing under one form is not satisfied is that its appetite is not intensively and extensively perfected and completed, as the Doctor shows (*ubi supra.*) But through the most perfect form virtually containing all the others, its appetite is both intensively and extensively perfected and completed, as Scotus teaches. (2. *d.* 14. *quest.* 1. §. *Respondeo. B.*) Therefore matter is entirely satisfied through it.

Second: the intellect of the blessed seeing God, who contains all things formally or virtually, is completely perfected and satisfied — according to the psalm: "I shall be satisfied when your glory appears." Likewise therefore matter is entirely satisfied by the aforesaid form.

Furthermore: that is said to be everywhere satisfied which has whatever it desires, as is clear from Augustine: (1. *Trin. c.* 5.) "Blessed is he who has whatever he wills." But matter informed by that form possesses whatever it desires, since it captures all other forms virtually through it.

One might say: the rational soul virtually contains the vegetative and sensitive, and yet the appetite of each kind of matter tends toward formally receiving them in itself — even toward the more imperfect ones. Again, the form of a mixture virtually contains the forms of the elements; nonetheless the form of the mixture does not so satisfy the appetite of matter that it does not also desire to be under another form — whether of an element or a mixture.

This must be handled: even though the aforesaid instances hold for those forms that do not at all satisfy the matter they inform, they do not hold for the most perfect form as described by the Doctor — because this form is supposed to fully satisfy the appetite of matter both intensively and extensively, just as the appetite of the will in the supreme and beatific object is completely quieted, so that it extends no further, as Vigerius notes. (*nuper alleg.*)

CLXXV. Objection I against Assertion I. Matter is indifferent and indeterminate toward any form; therefore it does not desire the more perfect more than the less perfect. I grant the antecedent and deny the consequence — because, together with its indifference and indeterminacy, it is consistent that it should more desire the nobler than the ignoble. Just as the light of the sun and of a lamp is indifferent for illuminating all parts of a hall, yet illuminates the closer parts more than the more distant ones.

CLXXVI. One might say: a surface that is indifferent to whiteness or blackness does not desire the one more than the other. Likewise, artificial matter that is indeterminate toward the form of Jupiter or of Mercury is not more inclined toward one than toward the other. Therefore the same must be said of natural matter with respect to its forms. The parity is to be denied, because both surface and artificial matter are in neutral potency toward those forms, whereas natural matter is in natural potency toward the aforementioned natural forms.

CLXXVII. Objection II against Assertion II. If matter underlying a nobler form desired an ignoble form, its appetite would tend toward evil — because a vile and imperfect form, in comparison to a nobler one, is something evil. For to lose the perfect in order to acquire the imperfect seems to be evil — not only in natural things but also in moral ones. Therefore, when matter is under a more perfect form, it does not desire a less perfect one.

I deny the consequence of the antecedent. For a vile and imperfect form is a substance; therefore it is simply and per se good — even though in a qualified sense and per accidens it may be called evil, because for it to be introduced into matter it is necessary that the preceding nobler form and its composite be corrupted, as Aristotle indicates. (*1. Phys. T. 81.*)

CLXXVIII. Objection III against Assertion III. The appetite of nothing can be completed and satisfied except in an infinite object containing every good, as Vigerius notes among others. (*praecit.*) But no form can be infinite. Therefore no form — however most perfect — can fill the appetite of matter.

I distinguish the major: of rational appetite, which is of infinite capacity regarding the infinite God — I grant; of natural or animal appetite — I deny. For this is completed in a finite object and satisfied in the most noble form virtually containing all other forms — if such a form were given.

Article XIV. Whether Matter Is Per Se Knowable

CLXXIX. That matter is not per se knowable is the teaching of Averroes, (*4. Phys. com. 17.*) St. Thomas, (*1. p. q. 87.*) and Aegidius. (*Quol. 2. q. 13.*) The opposite is defended by Scotus, (*2. d. 12. q. 1. §. Ad argumentum paulò ante R. Et 3. d. 22. q. vn. §. Ad 1. arg. H.*) Faber, (*Theor. 25.*) the Parisian school, (*1. Phys. q. 4. fol. 27.*) John of Magistris, (*q. 11. scib. d.*) Tartaret, (*q. 7. scib. 2.*) and others in the same place, who assert that matter is per se knowable.

CLXXX. Note I. That matter is known by us through the natural transmutation of one form into another. For since such transmutation requires a subject in which it occurs, that subject is called matter — and in this way it is apprehended by Aristotle (*1. Phys. T. 51.*) and defined by him (*ibidem Titul. 82. cap. 9.*) For we experience that something always corrupts and in its corruption something is lost — namely form — and something remains — namely matter. From this we argue that matter is the receptrix now of this, now of that form. And so by reasoning from effect to cause, our knowledge of matter is acquired, as the Doctor signifies. (*in 2. cit. post I.*)

CLXXXI. Note II. That something is knowable can be taken in two ways: one way, per se and absolutely, with respect to its entity, with no other prior cognition required — whether it is knowable a priori or a posteriori; another way, comparatively — that is, through relation and likeness to another. This occurs when something is so hidden from us that it cannot be known by us through its cause or its effect, but only through the likeness and analogy of another, by reason of which we are led to knowledge of it, as the Doctor suggests. (*7. Met. q. 2. §. contrà de inseparabilibus. Et 9. 5. propre finem.*)

CLXXXII. Assertion I. Matter is per se knowable. So Scotus (*ubi supra. Et 2. Met. quest. 2.*) and Anthony of Andrés. (*7. Met. quest. 12.*) It is proved first: every positive being is per se knowable, because knowability is a property of being. (*2. Met. T. 4.*) But matter is a real positive being, since it is a substance. (*12. Met. cap. 2.*) Therefore it is per se knowable. This is corroborated: every color is per se visible, since it is the object of sight; therefore every being is knowable, since being is the object of the intellect. But matter is a being and a substantial part of the complete physical being. (*8. Met. Titul. 3.*) Therefore matter is not excluded from the roster of per se knowable beings.

Second: what is definable is per se knowable, because definition is the instrument of scientific cognition. But matter is defined positively (*1. Phys. Titul. 82.*) and negatively. (*7. Met. T. 8.*) Therefore it is per se knowable.

CLXXXIII. Assertion II. Matter is knowable by us through likeness and analogy to form. So the Doctor. (*in 2. cit. propè finem eis q.*) It is proved first from Aristotle (*1. Phys. T. 69. & 2. eiusdem operis, T. 86. & 2. de generatione T. 53.*) speaking thus: "As the statue is to bronze and a bed to wood, so form is to matter." But we know that bronze is the matter of a statue and wood the matter of a bed. Therefore through the analogy of artifacts matter is known by us. For just as art in its works presupposes matter, so nature also requires matter beforehand for its operations. From this likeness of artifacts, therefore, we arrive at knowledge of natural things, as Averroes aptly explains. (*textum 69. primi Phys.*)

It is urged second: form is more knowable by us than matter; but form is not known by us except through operation; therefore neither is matter. But the effect of matter is to sustain form and together with it to cause the composite.

Therefore matter is knowable by us through its relation to form. The major is clear. The minor is at hand: from a new and diverse operation we argue a new and diverse form; likewise from a new transmutation, with the same subject persisting, we come to knowledge of matter, which is that subject. Furthermore, there are two contrary principles whose contrariety is exercised in a common subject, which is called matter. Moreover, from the sensible accidental form the subject of it is known — according to (1. *animae* T. 11.): "Accidents contribute greatly to knowledge of substance." It is clearly inferred that we pursue knowledge of matter from its relation and analogy to form.

CLXXXIV. Objection I. From (3. *de anima* T. 9. & 7. *Met. c. de partibus definitionis*): the philosopher, in enumerating per se knowable things, mentions form and the composite but not matter. Moreover (7. *Met. T. 35.*) he adds that matter is by itself unknown. Augustine adds: (l. 20. *contra Faustum cap. 14.*) "Prime matter can neither be sensed nor understood by itself." I respond to the two prior passages: Aristotle indeed affirms that form and the composite are known by us, but does not assert that matter is unknown to us. For he affirms one thing and does not deny another. An argument drawn from negative authority is not conclusive.

To the last: the Doctor says (*in expositione eius text. & 3. d. 22. quaest. vn. §. Ad 1. arg. sub H.*) that matter is called unknown because it is not the primary or most potent reason for knowing — but form is, which is the cause of knowing matter in the way stated above. By the same token satisfaction is given to Augustine, who, while indicating the difficulty of knowing it (l. *de natura boni cap. 18.*) writes that matter can scarcely be thought of through no species but through the privation of all species. And (12. *conf. c. 5.*) that we try to know matter by not knowing — or not to know it by knowing.

CLXXXV. Objection II. What is proper to form is not to be attributed to matter. But to be known by the intellect is proper to form; therefore it does not belong to matter. The major is clear. The minor is shown: to be received in a subject, to terminate and inform a subject belongs to form — hence Aristotle adds (3. *animae. T. 6.*): "The soul is the place of forms." I grant the major and deny the minor: for knowability belongs to every being. (2. *Met. T. 4.*) To the testimony of the philosopher I say that it is to be explained of intentional forms, such as intelligible species.

CLXXXVI. Objection III. What is not act nor has act is not per se knowable, because potency is a kind of latency and concealment. But matter is potency (8. *Met. T. 5.*) participating in no act; therefore it is not per se intelligible. The major can be denied, because being, which is divided into being in act and being in potency (6. *Met. T. 4. & 9. eiusdem operis T. 1.*) is per se intelligible. But if the major is granted, the minor must be distinguished: matter is subjective potency having no formal act — I grant; it is objective potency participating in no entitative act — I deny. In this way the testimony of the philosopher adduced must be interpreted.

Article XV. Whether Matter Is Ingenerable and Incorruptible

CLXXXVII. The common run of philosophers together with Aristotle (*1. Phys. c. 9. T. 82.*) grant that matter is ingenerable and incorruptible terminatively and objectively, yet generable and corruptible subjectively. But this manner of speaking, although common to both Thomists and Scotists, both ancient and recent, does not please two of our more recent authors. (*disp. 2. q. 8. art. 2.*) So that the truth of the matter may be evident and the common manner of speaking appear as true and genuine, we proceed.

CLXXXVIII. Note I. From (*5. Phys. T. 4. & 1. de gener. T. 23.*) generation is the transition or change from non-being to being with a subject presupposed, and corruption is the change from being to non-being with a subject remaining. From this it is not obscurely deduced that what is objectively or terminatively generable means nothing other than being the object or terminus of generation — so that what passes from non-being to being is generable, and what passes from being to non-being is corruptible. This terminus is twofold: the terminus quo, which is form, and the terminus quod, which is the composite. Since matter, once created by God, always remains and will endure perpetually, it is therefore said to be ingenerable and incorruptible. But what is generable and corruptible subjectively is what is presupposed and subjected to generation and corruption — and this is called matter, in which the transition occurs from non-being to being and from being to non-being, with it always persisting and remaining, as Aristotle sets out excellently. (*1. Phys. T. 80. & 82. & alibi non rarò.*)

This sense is embraced in common, and this doctrine is freely confirmed by Scotus, (*7. Met. quaest. 8. 10. Et 1. Rep. d. 5. q. 2.*) Anthony of Andrés, (*7. Met. q. 9.*) Canon, (*1. Phys. q. 9. art. 2. dub. 1.*) the Parisian school, (*1. Phys. q. ult.*) John of Magistris, (*ibid. dub. 1.*) Tartaret, (*q. 7. scibili 3.*) Richard, (*2. d. 12. q. 2.*) Bonet, (*1. d. 8. q. 2. q. 2.*) St. Thomas, (*1. p. q. 46. a. 1.*) and all the rest except the two recent authors mentioned, who, opposing themselves to the common sense and thinking that Aristotle is speaking of generation and corruption actively and not passively, in the character of production or destruction — and thus thinking that others are in error — are themselves in error. For those authors explicitly affirm that matter is the common subject of all natural generations and corruptions, not however that it is the subject or terminus of them and is denominatively generable and corruptible from them insofar as they occur in it as in their common subject. Let them read only the passages cited and they will evidently see the truth of the common saying. I add from Augustine (*5. Trin. c. 7.*) and Scotus: (*3. d. 6. q. 1. D.*) "When the matter is established, no violence should be done about the name." I add from Bartolus: (*in l. de nom. §. plurimum*) "In questions of name, common opinion makes truth." Since therefore those recent authors freely admit that through the distinction brought at the beginning of this article the difficulty about word and manner of speaking is resolved and

dissolved, no concern need be taken — especially since it is the assertion of Scotus, whose doctrine they publicly profess to follow.

CLXXXIX. Note II. Generation and corruption are taken in two ways. First, broadly and improperly, for any production, inception, or cessation. In this way, both what are properly created and annihilated, and others that come forth to light and cease to be in another manner, are said to be generated and corrupted. This sense is mentioned (*Gen. 2.*) "These are the generations of heaven and earth," and is indicated (*1. Caeli T. 112. & 113.*) Second, narrowly and properly, for substantial progression from non-being to being with a subject remaining, and from being to non-being with the same subject persisting — and this is called natural generation and corruption, as John of Magistris notes. (*nuper alleg.*) This twofold sense is also taken by the word "is made" — first (*Gen. 1.*): "Let light be made," and (*1. Phys. T. 58.*): "From a musician a musician is made," and (*1. de gener. 13.*): "From the whole mixture blood is made." The second sense: (*Gen. 2.*) "The human being was made into a living soul," and (*1. Phys. T. 64. 6. 8. Met. T. 8.*): "Only the composite is made" — that is, is generated.

CXC. Assertion I. Matter is objectively generable and corruptible in the broad sense of the word. This is derived from Scotus (*2. d. 12. q. 1. §. dico igitur.*) and John of Magistris expressly favors it. (*passu memorato.*) It is proved first from Sacred Scripture: (*Ioan. 1.*) "All things were made through him." But matter was made — that is, created — as I proved in Article IV of this question. Therefore before it was made it was makeable and producible and generable and corruptible in the broad sense of the word.

Second: all things except God are in the aforesaid manner generable and corruptible. For God alone is supremely necessary, unproducibile, and incorruptible. Therefore, since matter resides in the series of created things, it follows that it is generable and corruptible in this sense. Here too belong the things I brought forward in the tract on creation, (*disp. 1. q. 17.*) to show that, except for God, all things are causable and makeable — even according to Aristotle.

CXCI. Assertion II. Matter is generable and corruptible subjectively. The Doctor holds this. (*7. Met. q. 10.*) It is proved first from Aristotle (*8. Met. T. 4.*) calling the matter of sublunary things generable and corruptible. And (*3. Phys. T. 6.*) in defining motion he gives the example of generation and corruption. Generation is the act of the generable as generable, and corruption is the act of the corruptible as corruptible; but what receives these acts is matter. Therefore in the Peripatetic school, matter is generable and corruptible subjectively.

Second: form existing in a subject denominates formally the subject in which it exists — as whiteness inhering in a wall denominates it white. But generation and corruption are formally in matter, since matter is the common subject of

generation and corruption. (1. *Phys. T.* 82.) Therefore they denominate it generable and corruptible — and thus matter is generable and corruptible.

Third: whatever changes from non-subject to subject is generable, since generation is change from non-subject to subject. (5. *Phys. T.* 7.) And what changes from subject to non-subject is corruptible, since corruption is change from subject to non-subject. (*ibid.*) But matter changes from non-subject to subject — as from non-water to water — and from subject to non-subject — as from water to non-water. Therefore matter is subjectively generable and corruptible.

CXCII. Assertion III. Matter is ingenerable and incorruptible terminatively. This is defended by the Doctor. (7. *Met. q.* 8. & in *Report. praealleg. q.* Et 2. d. 1. q. 3. §. Ad. 1. arg. principale sub K.) And it is the express doctrine of Aristotle. (1. *Phys. T.* 82.) It is urged first: matter is subjected to every generation and corruption, and a natural agent does not act except upon prior-existing matter. Hence it is described (2. *Phys.* 28. & 5. *Met.* 2.) as that "from which existing within it something comes to be." For what is generated is born from matter, and what is corrupted is resolved into matter. (1. *Phys. T.* 82.) Therefore matter is ingenerable and incorruptible terminatively.

Second: what is creatable and annihilable is ingenerable and incorruptible terminatively — as is clear of the Angel and the rational soul. But matter is creatable — and in fact was created at the beginning of the world — as I showed in Article IV of this question. Third: the terminus of generation is either total or partial. Matter is not the total terminus of generation, because that is the composite. Nor is it the partial terminus, because that is form. Therefore matter is ingenerable terminatively.

All the more so: generation and corruption occur in sublunary things for the most part from contraries and from what is repugnant; but nothing is contrary to matter — on the contrary, matter is itself the willing common subject of contraries and the foundation of all forms. Therefore it is not subject to generation and corruption.

CXCIII. Objection I against Assertion III. From (7. *Met. T.* 22. Et 8. *eiusdem operis T.* 4.): matter of these lower things is said to be generable and corruptible. Therefore the last assertion conflicts with Aristotle. I respond through the distinction brought forward: matter is generable and corruptible subjectively and denominatively — I grant; objectively and terminatively — I deny. The philosopher's testimonies cited are to be explained in this way.

CXCIV. Objection II. What is the cause of generation and corruption is generable and corruptible. But matter is such; therefore etc. The major is supported by that axiom: (1. *post. c.* 2.) "That by reason of which each thing is such, that thing is more so." The composite is corruptible on account of matter desiring another form; therefore matter itself is more corruptible. The minor is

from Aristotle. (*1. Phys. T. 80.*) "Matter stripped of form contrives harm" — namely, the corruption of the composite. I distinguish the major: in univocal and efficient causes — I grant, as if a hand is cold because of frost, frost is more cold. In equivocal and material causes — I deny. For it does not follow that a person is drunk because of wine; therefore wine is more drunk. In this way the philosopher's maxim is explained.

CXCV. Objection III. What can do the more perfect can also do the less perfect — for what can do the greater can do the lesser, as is established by the argument from the greater to the lesser. But a natural agent can act upon the composite, generating and corrupting it, which is more perfect than matter. Therefore it can also generate and corrupt matter. This is corroborated: the principles of a corruptible thing are themselves corruptible. Since therefore the whole is corruptible, its principles — among which is matter — are corruptible. The antecedent is from Aristotle. (*1. Caeli, 61.*) Furthermore, generation is a change of the whole into the whole, with nothing sensible remaining. (*1. de gener. 24.*) Therefore if the whole is corrupted, whose one part is matter, matter itself is also corrupted.

I distinguish the major: if it is of the same nature and within the sphere of its activity — I grant; if it is of a different nature and outside the sphere of its activity — I deny. For it does not follow that a human being generates a human being, who is more perfect than a dog; therefore it also begot a dog, who is less perfect than it. To the distinction of the major, the minor is to be distinguished. To the corroboration the antecedent is denied universally. To its proof I say that the philosopher's saying is indefinite. For even though it is true of form and privation, it is not true of matter — just as the principles are contrary, namely form and privation, but not matter.

To the other thing added, I say that it is to be understood with respect to the third entity, which is entirely corrupted and another new one entirely generated — not however with respect to all parts; for some persists, which is the common subject of generation and corruption, as Aristotle notes, (*1. Phys. 60. Et 8. Met. c. 2.*) and Scotus (*4. d. 11. q. 1. q. De primo. A.*) and Anthony of Andrés (*ad finem exp. 6. princ.*)

CXCVI. Objection IV. The incorruptible surpasses the corruptible in dignity — just as the immortal surpasses the mortal and the eternal the temporal. But form and the composite are more excellent than matter, since matter is the lowest and most refined being. Therefore matter is not incorruptible, otherwise it would surpass form and the composite in perfection and dignity — which are corruptible.

I distinguish the major: simply — I deny; in a qualified sense — I grant, as is clear of the heaven, which is incorruptible and to which any animate living being is preferred, even though the latter is incorruptible and the former

corruptible. Likewise an element according to the whole is incorruptible and yet is ranked after the corruptible mixture.

One might say: matter needs form in order to exist and subsist, since it is a partial and imperfect substance. Therefore if deprived of all form — which God can do — it would perish and be corrupted; therefore it is not alien to corruption. I say that even though in the order of created things established by God matter is never without form and its appetite is fulfilled through form and it is perfected thereby — nonetheless, given the hypothesis, through the general concurrence of God it would exist per se, since it enjoys its own proper existence and subsistence, as I showed in Articles VI and VII of this question.

Article XVI. What Is the Root Cause of the Corruption of Natural Things

Since we observe around us the unceasing destruction and continual corruption of things, it is fitting to investigate and examine what the original cause of this might be — whether it is form, matter, or something else altogether. Avicenna, in (*1. suff. cap. 3*), holds that sublunary things are assailed and corrupted by contraries. Averroes, in (*l. de substantia orbis*), thinks that the destruction of things arises from contraries and from matter. But the Canonist (*1. Phys. 9. 9. 4. 2. dub. 2*) and John of Maisières (*ibid. quaest. 13. dub. 2*) judge that the corruption and perishing of composites originates from form. However, the common body of philosophers, together with Aristotle (*1. Phys. c. 9. T. 81*), teaches that the root of corruption arises from matter alone.

I do not here rehearse the various modes and degrees of corruption that I explained in the Moral treatise (*1. 5. 9. 2. art. 10*). I note only, following Aristotle (*l. de longitudine et brevitate vitae*) and Scotus (*2. Rep. d. 12. q. 1*), that the principle and cause of corruption is twofold: an active cause, by which a corrupting agent corrupts what is corruptible, and a passive cause, by which the corruptible is corrupted. This is further divided into intrinsic corruption, by which something has an internal principle of corruption, and extrinsic corruption, by which something is corrupted by an external principle. It can also be subdivided into primary corruption, which is the first origin of corruption, and secondary corruption, which follows from and depends upon that primary root. Again, there is remote corruption, by which something lacks the prior dispositions leading to corruption, and proximate corruption, by which something participates in qualities suited to produce corruption. Further, there is subjective corruption, by which a subject is made subject to corruption, and objective corruption, by which something is the object or terminus of corruption. Finally, I note that almost all of these causes of corruption are reducible to one fontal and radical cause, which is intrinsic. For there would be no extrinsic corruption if there were not first intrinsic corruption — since an agent would not act upon a subject unless that subject were capable of receiving its action; and likewise, a corrupting agent would corrupt nothing unless the

subject were open to undergoing corruption, as the Doctor agrees (*2. d. 12. q. 1*) and (*3. d. 12. q. vn. §. Rationes ante C*).

The source and primary root of the corruption of natural things is matter clothed in privation. This is the position of the Doctor just cited (*2. d. 12. q. 1*), together with his disciples. It is proved, first, from Aristotle (*1. Phys. T. 80*): "Matter, deprived of form, contrives mischief" — that is, the corruption of the composite — as the commentators explain there. Second, what is immaterial is incorruptible — as is the angel and the rational soul — while what is material is corruptible; therefore matter is the origin and cause of corruption. One might object that the heavens are material, being composed of matter and form, yet are incorruptible, and so matter cannot be the primary and adequate reason for corruption. Scotus responds (*2. d. 14. q. 1*) and (*4. d. 49. q. 6. §. Hic duo sunt sub B*) that the heavens are corruptible in a remote and absolute sense, yet incorruptible in a proximate and qualified sense, because no natural agent is found capable of overcoming their power and corrupting them. Third, matter desires the form it lacks, as something suited to its good; but it cannot possess a new form without the corruption of the form it currently enjoys, and that form is not corrupted without the whole composite being corrupted. Moreover, matter is in a state of contradictory potentiality — toward being and toward non-being (*7. Met. T. 22, and frequently elsewhere*). It has the capacity to receive a form of which it is currently deprived, just as a place is capable of receiving what is placed in it. And, more to the point, matter receives contraries, one of which cannot coexist with another; thus, when one form recedes, the privation of the other arrives. Now that which receives what harms and destroys another is the cause of its demise and corruption. Therefore, since matter is the common receptacle of contrary principles — namely form and privation (*1. Phys. T. 68*) — matter is undeniably the root of corruption.

Objection I. Where there is no contrary, there is no corruption (*1. Caeli T. 20*) and (*1. de long. et brev. vitae*). Matter has no contrary (*1. Phys. T. 67*). Therefore matter is not the cause of corruption. Confirmation: matter is ungenerable and incorruptible, as was established in the previous article. Therefore it is not the origin of corruption. Response: the major premise holds for corruption proceeding from an extrinsic source, but not for corruption emanating from within, which is what we are discussing here. Hence Scotus, just cited, says that the heavens are in fact incorruptible because no natural agent capable of overpowering and corrupting them is to be found. To the confirmation: I concede the antecedent but distinguish the consequent — in itself and absolutely, I concede; when joined with privation and its own potentiality, I deny — as the Doctor explains (*3. d. 22. q. vn. ante C*).

Objection II. What is the cause of change is the cause of corruption, since corruption is a change (*3. Phys. T. 6*). But form is the cause of change (*1. Phys. T. 68*), since when form informs matter the composite is generated, when it

persists the whole is conserved, and when it departs and is absent the whole is corrupted, as the Philosopher acknowledges in the passage just cited. Therefore form is the cause of corruption. Confirmation: if a preceding form were to coexist with a subsequent form, no corruption would occur, because no change would occur; therefore, since corruption happens through the separation or cessation of form, it clearly follows that form causes corruption. I concede the major; I distinguish the minor: as primary and radical cause, I deny; as secondary and accidental cause, I concede. For just as a sailor by his presence is the conserving cause of a ship and by his absence is the cause of its sinking, as Aristotle notes (*2. Phys. T. 50*) and the Doctor accepts (*2. Rep. d. 34. q. 1*) — so when form is present the composite is conserved, and when it is absent the composite is corrupted. To the confirmation: the same must be said. For even if the composite is not proximately corruptible as long as form remains, it is nonetheless corruptible remotely, on account of the potentiality of contradiction that exists in matter, as was established from Aristotle and Scotus cited above.

Objection III. If form were fully to satisfy the appetite of matter, corruption would not occur. Corruption occurs precisely because the appetite of matter is not satisfied by form. Hence the Doctor adds (*1. d. 1. q. 1*) that if there were given a most perfect form containing all other forms virtually, the desire of matter would cease. Therefore corruption derives from the form that fails to satisfy matter's appetite. Confirmation: as was said above, form is generable objectively and terminatively, being the object and terminus by which generation is directed; therefore it is also corruptible terminatively, and since it is possible and in a state of contradictory potentiality, it follows that form itself is the origin of corruption. Response: even on that hypothesis, although corruption would not actually occur, it would remain possible — since the root of corruption, which is inseparable from and intrinsic to matter, namely its potentiality of contradiction, would remain, as Scotus notes from (*2. de gen. T. 51*) in (*2. d. 12. q. 1. infra A*). For matter existing under that most perfect form would still be capable of being under another form, whether equal or inferior, and would therefore not be exempt from corruption. To the confirmation: I concede that form is corruptible terminatively; but I deny that it is the primary origin of corruption, which is the whole point of the dispute.

Article XVII. Whether Matter Is Purely Passive

Some hold that matter possesses no activity whatsoever, as those cited by Mayr (*2. d. 12. q. 1. art. 5*), followed by Toledo (*1. Phys. q. 11*), Ruvio (*tract. 1. de mat. q. 9*), and Vasquez (*1. p. disp. 196. n. 13*). On the other side, the Manicheans cited by Augustine (*lib. de natura boni cap. 18*) make matter the maker of all corporeal things, and some even suspect it to be God the maker of all things, as Aquinas reports (*1. q. 9. 3. art. 8*). Others, however — such as Scotus (*3. d. 12. q. 1*), (*2. d. 14.*

q. 1), Mayr as just cited, Arriaga (*disp. 2. Phys. sect. 9*), and Poncius (*ibid. ad finem disp. 32*) — treat matter as passive, yet without stripping it of all activity.

Note I. There is not just one question about the activity of matter. One can inquire whether matter is the origin and cause of its own properties; whether it is active in the eduction of the form drawn from its potency; whether it cooperates in the generation of the whole; whether it is a partial cause of the operations proceeding from the whole; and finally, whether it moves the intellect to the knowledge of itself, as other knowable objects do.

Note II. From the Doctor (*1. post. q. 25. §. Ad quaestionem respondeo*), there are two kinds of cause. One acts by transmutation, as a plant produces its flowers and a tree its fruits; the other acts by emanation, as risibility proceeds from humanity and the divine attributes from the Divinity. Again, a cause is divided into physical or real — which emits its effect outside itself, as fire emits heat — and intentional, which receives within itself the operation it produces, as the intellect produces an act of understanding, which is called an intentional action, as will be established and explained elsewhere.

Note III. Among the properties of matter, the following are most important: its ungenerability and incorruptibility, its perpetuity and passibility, its appetite for forms, and its knowability by analogy with forms — all of which are sufficiently evident from what has been said above, and are explained by recent authors, particularly Ruvio and Arriaga as cited.

Assertion I. Matter is the cause of its own properties. This is drawn from the Doctor (*2. loco cit.*), (*ibid. d. 16. q. un.*), (*4. d. 12. q. 3. §. Dico ergo sub E*), (*d. 13. q. 1. §. De tertio art. ante CC*). It is argued, first, that properties or attributes flow most of all from the specific nature, as I explained in the Epitome (*lib. 1. quaest. 3. art. 6*). Now matter is a specific nature, albeit an imperfect and partial one, as I proved in article XI of this question. Therefore its properties arise from matter itself, and it is therefore their cause and origin. Second, every effect requires a cause, since these are correlatives, each requiring the other. But there are several properties that are like effects of matter and proceed from no other cause but matter itself — not from form, nor from the composite, which are generable and corruptible. Someone might say that properties proceed from an act or from something that includes an act, and not from a pure potency such as matter. But on the contrary, matter has an entitative act, as I showed in the present question, article V. It is a substance, whose properties are enumerated in logic in the chapter on substance. Moreover, from matter itself there arise relations of similarity and dissimilarity: one matter is similar or dissimilar to another. Therefore not all active power is removed from matter.

Assertion II. Matter, in its own material genus, cooperates in the eduction of form from its potency. This is drawn from Scotus in the places cited in the previous assertion, and more explicitly (*4. Met. in exp. Tit. 20*) and (*8. eiusdem*

operis, in Tit. 14). First proof: matter is "that out of which something comes to be while it is present in it" (*2. Phys. Tit. 28*). If, therefore, matter cooperates in the generation of the composite, it also cooperates in the eduction of form, since form depends upon matter both in its becoming and in its being. Second, an immaterial form is introduced into matter from without, while a material form is drawn out from it; therefore matter in some way co-acts in its production. Perhaps this is why it is called "material," because it is caused from matter. Furthermore, if matter were merely presupposed for the production of form and contributed nothing to it, then if form preexisted and were presupposed to matter, one would say it comes to be from the preexisting form — just as it is said to come to be from the preexisting matter. But this is false. Therefore, for a form to be drawn from the potency of matter means nothing other than that matter cooperates in the production of that form, as Mayr rightly saw. Someone might say: if matter causes form, then since both are principles, one principle would come to be from another, which contradicts (*1. Phys. Tit. 42*). The inference is denied, because, as I said in question I of this book, article I, note II, "to come to be" properly belongs to the composite; and so it is only in an improper sense that form is said to come to be — properly speaking, it is drawn out from the potency of matter by an agent.

Assertion III. Matter exercises partial activity in the generation of the whole. The Doctor supports this (*3. d. 2. q. 2. art. 1. §. Quantum ad 1. C*). First proof: from (*7. Met. Tit. 7*) and (*8. eiusdem, cap. 2. Tit. 3*), the composite is said to be a third thing caused from matter and form as two partial causes that together make up one total cause. Second, matter is one of the four genera of cause (*2. Phys. Tit. 28*), and it causes the composite partially, because the whole arises from it and form together. Therefore matter performs the function of a cause in the generation of the composite. More on this when I treat the composite.

Assertion IV. Matter does not cooperate in the operations of the whole. This conflicts with Poncius as named above, but is favored by the Doctor, who in the third assertion cited above makes the whole distinct from its parts taken together. Therefore the actions that proceed from the whole do not proceed from its parts — especially from matter, which is passive. First proof: from (*1. de anima Tit. 64*), where the Philosopher denies that actions belonging to the whole — such as building and weaving, and those attributed to a human being — belong to the soul; therefore neither form nor matter cooperates in those works, otherwise they would in some way be attributed to them. Second, if matter cooperated in the works of the whole, it would be knowable from those works, just as form is known through its operations. But matter is not knowable by us except by analogy with form, as I showed above in article XIV of this question. Therefore it contributes nothing to the works of the whole. Third, if matter were to cooperate actively in the effects of the composite, mixed things would not be distinguished from the elements, nor would animate things be distinguished from inanimate, nor would there be any distinction between these and those

species of things, since they all share the same common matter and the same active principle. But it is established that the genera, species, and individuals of things are diverse, as are their faculties and operations. Hence Lucretius sings: "And in this matter it is impossible that all things come from all things, for in certain things there resides a hidden power."

Assertion V. Matter can act upon an intellect freed from the senses by an intentional action. This is indicated by the Doctor (*2. d. 12. q. 1. Ad arg. R.*). First proof: an object moves a faculty to an intuitive cognition of itself when present, or by means of a species representing it when absent. But matter is a per se intelligible object, being a substantial being. Therefore it can act intentionally upon the intellect. Second: just as the sensitive relates to sensibles, so the intellective relates to intelligibles (*3. anima cap. 1. Tit. 3*). But the sense is acted upon by the sensible — it is moved by it to sensation — therefore the intellect too is moved by the intelligible, of which sort matter is. Third, quantity is considered by all to be in the genus of passive things, yet by an intentional action it moves the cognitive faculty to knowledge of itself, since it is known by us as the primary accident of corporeal and material substance. Therefore, even though matter is passive, it must not be excluded from intentional activity.

Objection I. From (*1. de gen. Tit. 55*) and (*2. eiusdem Tit. 52*): it belongs to matter to suffer. Augustine gives the reason in (*lib. de natura boni cap. 18*), comparing matter to a wood or forest. For just as a wood is suited to have something made from it, but not to make anything itself, so matter makes nothing; rather, something is made from it, namely the composite. Confirmation: efficient cause and material cause do not coincide, for they are two generically distinct causes (*2. Phys. Tit. 31*). Therefore neither is matter the effecting cause of its own properties nor of anything else. Response: I explain the Aristotle passages by means of a distinction. Matter suffers insofar as it receives form — I concede this. But insofar as it causes its own properties, or the composite, or anything else — I deny it. In this sense, sensing and understanding are said to be a kind of suffering. For just as the sense in receiving sensation is passive, but in causing it is active — so the intellect suffers insofar as it receives an act of understanding, but acts insofar as it produces it. The same response applies to Augustine's authority and the confirmation, which Scotus supports (*2. d. 25. q. vn. §. Ad 1. sub V*), giving the example of a physician who, insofar as he induces health in himself by his art, is called active; but insofar as he receives it, is called passive.

Objection II. A second act, which is action, presupposes a first act, which is its principle. But matter is neither a first act nor does it include a first act, being pure potency (*8. Met. Tit. 5*) and (*12. eiusdem, Tit. 22*). Therefore matter is not active in anything. Confirmation: properties arise from a specific nature, which is constituted and determined by its proper difference — as whinnying comes from equinity. But matter belongs to no species, since it is indifferent and indeterminate. Therefore it does not produce its own properties. Response: I

concede the major; I distinguish the minor. It is not a formal act — I concede. It is not an entitative act — I deny. It is indeed a potency, but not an objective potency — a subjective one, as I made clear in article V of this question. To the confirmation: granted the major, I say as to the minor that matter is specifically one in an incomplete, not a complete, sense, as was said above in article XI.

Objection III. If there were no matter, the effects that are now caused would still be caused — for instance, heat would cause heat, and snow would cause cold.

Therefore matter is the cause of nothing, since it produces no effect.

Confirmation: matter does not virtually contain form or anything else.

Therefore it is purely passive. Response: although not all effects proceed from matter — since form is more active — nonetheless, without matter, neither material form, nor the composite, nor any other operations would be produced, as the Doctor demonstrates well (*2. d. 12. q. 1. §. positio ista*). To the confirmation: I deny the antecedent, since it is asserted without proof. Therefore it is dismissed with the same ease with which it was advanced.

Article XVIII. Whether There Is a Seminal Reason in Matter Co-Eternal with It

This difficulty appears quite hard and arduous to both ancient and modern philosophers, both on account of its considerable obscurity and on account of the multiple disagreements among great men, as Mauritius notes above others (*in 7. Met. quaest. 12*), and as St. Bonaventure touches on (*2. d. 18. q. 3*). On this topic there are two principal positions. The affirmative position is attributed to Albert by the Scotist commentators (*Scot. 2. d. 18. q. un.*) and to Henry (*Quol. 4. q. 14*), who hold that form preexists in matter as co-eternal with it, cooperating with the extrinsic agent in generating the composite. Five modes of this opinion are adduced and refuted by Scotus (*7. Met. q. 12*) and Antonio Andrea (*ibid. q. 11*), and two by the Seraphic Doctor in the passage cited. One mode alone is treated by Durandus (*2. d. 12. q. 2*) — that of a pure possible residing in matter, distinct from it, transmutable into form, which he calls the seminal reason or inchoation of forms. These modes have been so thoroughly contested, routed, demolished, and nearly extinguished by the Doctor (*in loco cit.*) and also (*2. d. 18. q. un.*), by Bassolis (*ibid.*), Richard, and others, that one is almost reluctant to add anything further, and hardly anyone is found at this time who attempts to defend them. The negative position, which these authors embrace, teaches that nothing of form preexists in act in matter.

For the understanding of this, I observe with the Canonist (*2. Phys. q. 1*) that being is divided into actual and potential, and potential being is subdivided into subjective and objective — the explanation of which is known from what has been said above. I also observe, with the same author there, that when it is said that an active principle is found in matter, this can be taken in two ways: in one way, as the whole general or particular form, and in this sense there is no active principle in matter; in another way, as a certain prior disposition of the form to

be generated, and in this sense such a principle in matter can be granted as an instrumental active principle for the production of a new form. It is perhaps in this sense that Augustine speaks (5. 9. *Super Gen. prop. finem*), saying that in a grain of wheat there is a power by which wheat rather than a bean is produced from it, and in a bean there is a power by which not wheat but a bean is produced. This is noted by the Canonist (2. *Phys. q. 1. dub. 4*) from Averroes (6. *Met.*).

Assertion. Nothing actual or possible of form exists in matter before generation. The assertion is twofold, defended by Scotus in the passages already narrated. The first part is proved, first, from (1. *Phys. T. 82*), where Aristotle makes matter alone to be ungenerated and incorrupt — for it is the primary subject from which all natural things come to be, and into which they are all ultimately resolved. And in (7. *Met. Tit. 29*), he adds that, just as a house comes to be from an extrinsic principle alone, namely from an intelligent agent, so fire is generated not from an intrinsic but from an extrinsic principle only. Therefore, according to Aristotle, nothing is found in act in matter that always remains with it for the production of a new form and the generation of a composite. Second, contrary principles do not simultaneously persist in the same subject, especially if they are privative contraries, of which one denotes the absence of the other in a suitable and fit subject, as I explained in Logic (*lib. 3. q. 9. art. 6*). But privation and form are privative contrary principles (1. *Phys. Tit. 66 and 67*). Therefore, when privation is present in matter, nothing of form exists in it.

Someone might say there is something of an imperfect form in matter. On the contrary: between privative opposites there is no intermediate, just as between contradictory opposites (10. *Met. Tit. 15*). Therefore between form and its privation there is no such thing as an imperfect form or inchoation of form. For either form is in matter, or privation of it is — as the Philosopher argues (1. *Phys. cit.*). But before generation, form is not actually in matter; therefore only its privation is there. Third, the termini of a motion are incompatible (5. *Phys. Tit. 26 and at the end of that book*). But privation and form are the termini of generation — privation being its terminus from which, form being its terminus toward which, and their common subject being matter (1. *Phys. Tit. 60*). Therefore nothing of form always remains in matter as co-eternal with it. Fourth, form is impartible and invariable, from the book of the Six Principles, cap. II, and this is signified in (8. *Met. cap. 5. Tit. 10*): "Substances are like numbers, to which no addition or subtraction is made, otherwise they do not persist as the same." Now form is a substance, which in respect to essential and specific being admits no more and less, but only in respect to individual being. Therefore one part of it is not co-eternal with matter while another part is newly produced by the generating agent, since it is simple and indivisible. I add the simultaneous incompatibility of forms in the same matter, their syncategorematic infinity, parity with accidental form which does not precede in act before being drawn from its subject, and with artificial form which is

extracted from a subject by the artisan when nothing of it preexisted in that very subject — as Antonio Andrea shows together with the author of the Six Principles in the exposition of the cited chapter.

The second part is proved, first: every potential and possible being is either subjective or objective, as I observed not far from the beginning of this article. But that pure possible which the adversaries locate in matter — lest form come to be from nothing — is not subjective, since Aristotle in (*1. Phys. esp. c. 9*) admits no other subjective being besides matter. Nor is it objective, since this is the terminus of active potency, and the pure possible located in matter is not of this kind. Someone might say: it is not matter itself, but something possible in matter, transmutable into form. On the contrary: what is in matter is either a property of it — but this is not the case, since a property always remains in it, whereas this does not always remain but is transmuted into form — or it is something really distinct from matter. But it is not privation, which does not pass into form since privation is its terminus from which; nor form itself, which is its terminus toward which; nor the composite, which is the total and adequate terminus of generation. Therefore it is nothing, and thus the adversaries do not avoid the creation of form, which they strive to escape by means of that pure possible.

Second: every being is either actual or potential (*9. Met. T. 1*). But the pure possible imagined in matter is not an actual being, as its very name indicates, nor a potential being — since this is either subjective or objective — and the first argument recurs. Third: that pure possible resides in matter before form is produced from it, just as privation is present in matter when form is absent. Therefore, if it actually exists in matter, it is an actual being, because no being is found in another unless it is an actual being. Therefore, if it is an actual being, it is either uncreated — and is God — or created and produced from nothing, which the said authors deny. And if they say it is a potential being, since the possible does not yet exist, or it comes to be from something, and unless we proceed to infinity, we must assign that from which it comes to be — which cannot be anything other than matter — yet they distinguish it really from matter and hold it to be incapable of being made. And furthermore: the pure possible is in act nothing; therefore if form comes to be from it, it comes to be from nothing — which they refuse.

Objection I. Against the first part of the assertion: Aristotle (*7. Met. T. 29. cap. 9*) writes that in matter there pre-exists a part of the thing to be generated. Therefore, in the Peripatetic tradition, something of form preexists in matter before the generation of the whole. Augustine adds (*7. cap. lib. 3. de Trin.*): "The hidden seeds of all things that are born lie concealed in the elements of the world." Hence Augustine himself (*lib. de natura boni cap. 18*) calls matter a "wood," because just as from a wood planted with trees artificial works are made, so from the forms preexisting in matter natural composites are generated. Response: I

explain the Philosopher's text with Scotus there in the commentary — by "part" he understands a cooperating power in the generation of form, just as prior dispositions dispose matter and cooperate instrumentally in the production of form. Likewise, the potencies and faculties of the soul are called its "parts" by the same author (3. *anima* 1), as Scotus notes (2. d. 16. q. un.) together with the Seraphic Doctor (*ibid.* d. 24. q. 1. art. 2). For this reason Boethius (*lib. divis.*) divides the soul like a whole into virtual parts. The same response applies to the first passage from Augustine — for the same saint plainly acknowledges, in (3. *de Gen.*) and (5. and 9. *eiusdem operis*), the aforesaid active power in the generation of trees and animals, as Richard rightly noted (2. d. 18. q. 2. art. 1). To the second passage: the comparison holds in this respect, that just as an artisan draws out artificial forms from the trees in a wood, so a natural agent draws out natural forms from matter. But just as there are no actual artificial forms in the wood, so neither are there actual natural forms to be found in matter, as Aristotle signifies (1. *Phys. T.* 69 and 2. *eiusdem operis T.* 86).

Objection II. Unless form preexists in matter in some manner, there would be generation but not creation — for form would be produced from nothing of itself. But creation is the production of a thing from nothing. Therefore either part or the whole of form preexists in matter as co-eternal with it. I deny the inference of the major. The reason is that form is produced not from nothing but from preexisting matter; therefore it is not creation, which is production from no presupposed subject, as the Doctor teaches (2. d. 1. q. 2).

Objection III. If form does not precede generation in any respect of its being, generation would not be natural but violent — because it would lack an intrinsic principle, which is required for it to be natural, and would have only an extrinsic principle, which renders it violent, since the violent is that whose principle is extrinsic (3. *Eth.* 1). Therefore in some respect of its being form precedes generation. I deny the inference of the antecedent. For generation participates in an intrinsic principle — not indeed an active one, but a passive one, naturally inclined toward form, which is all that is required for what is properly called natural, as the Doctor sharply explains (2. d. 18. q. un. §. *Contra D.* 1).

Question III. On Privation

Since in matter privation precedes form, as Scotus notes (3. d. 3. q. 1. §. *si autem G*), because privation is the terminus from which of generation, as Aristotle says (5. *Phys. Tit.* 7), and as Antonio Andrea expresses (10. *Met.* q. 4), while form is the partial and principal terminus toward which, which is undoubtedly posterior to the former — for this reason we treat of privation before form.

Article I. Whether Privation Exists

There are those who deny privation any existence on the side of the thing, among whom are numbered Soncinas (10. *Met.* q. 15) and other Thomists, who

hold that it depends solely on the intellect and is therefore a being of reason. The more common opinion, however, is that of Scotus (*1. d. 23. q. un. §. Item arguo H*) and (*4. d. 22. q. 1. §. De primo A*) and (*Quol. 18. §. Ex isto Y*), Auriol (*2. d. 2. art. 2*), Mayr (*Quol. 7. punct. 5*), Parisian (*1. Phys. fol. 25*), and the other Scotists, who hold that privation exists on the side of the thing independently of any intellectual operation.

Note I. From Scotus (*1. d. 23. q. un. §. Item arguo H*) and (*in Rep. d. 28. q. 1. §. A. quaest. dico*) and Durandus (*d. 23. q. 3*), privation is taken in three ways. In one way, for the lack of something of which something is capable — not according to genus or species but according to a common and transcendental notion — so a person is said to be deprived of the supreme and infinite perfection that a being, or God, is naturally disposed to participate in, and this is called privation outside the genus. In a second way, for the lack of something that something is naturally disposed to have according to its genus — so a mole is called blind because, as an animal, it is capable of sight, and this is called privation in the genus. In a third way, for the lack of something in a proper subject according to species — so a person who does not see is properly said to be deprived of sight, or blind. The first two acceptations are improper and are called negations rather than privations. The third is the proper sense, which is under discussion here.

Note II. Privation and negation are not infrequently confused with one another, but they are distinguished in this: negation exhibits no aptitude or capacity in the subject of which it is said — so a stone is said not to see, because it is in no way capable of sight. Privation properly speaking, however, denotes capacity and suitability in the subject of which it is predicated — in this manner a person deprived of sight is said to be blind, as Augustine suggests (*lib. 3. de lib. arb. cap. 24*). More on this in Logic (*lib. 3. q. 9. q. 6*).

Assertion. Privation is conceded to exist in the nature of things independently of any intellectual operation. So Scotus as cited, and (*2. d. 12. q. 2. §. Ad 1. rationem sub F*) and (*5. Met. with Arist. cap. 22*). First proof: from Sacred Scripture (*Gen. 1*): "Darkness was upon the face of the deep" — that is, privations of light, according to the interpretation of Lyra there. Second proof: from the Fathers — Augustine (*lib. de decem categ. cap. 18*) and (*in imperfecto de gen. ad lit. cap. 5*): "One thing is light, another are those privations of light which God arranged in the contraries called darkness"; Anselm (*lib. de casu Diaboli cap. 41*) and Damascus (*cap. 2. of his Philosophy*). Third: opposites exist on the side of the thing, as is clear with contrary opposites such as heat and cold; but privation and form are opposites, as is evident in the postpredicaments chapter on opposites. Likewise, privation is established as a principle of natural generation (*1. Phys. T. 75, 79*) and as a terminus of change (*5. Phys. T. 7*). Furthermore, privation, as has been said, means nothing other than the absence of form in a suitable subject. But such an absence is sometimes found in the nature of things — night is a privation of light in the air, blindness is a privation of sight in a blind person, deafness is a

privation of hearing in a deaf person, and so with the rest. Therefore privation cannot be denied existence on the side of the thing.

Objection I. Non-being is not on the side of the thing, because non-being is tantamount to nothing; but privation is a non-being (*1. Phys. T. 75 and elsewhere*). Therefore privation is not on the side of the thing. Response: I distinguish the major. Non-being is not on the side of the thing absolutely, as something participating in positive being in the nature of things — I concede. It is not on the side of the thing in some manner, as the terminus from which of a positive being — I deny. For privation is in this manner, as Aristotle indicates (*4. Met. Tit. 2*) and Scotus there, when they count privations and negations among the substances and accidents that stand in relation to them, and which are said to be insofar as they in some way regard those positive beings, as the Doctor notes there.

Objection II. Everything that is, is either a real being or a being of reason. But privation is not a real being, since it is the negation of a real form. Therefore it is a being of reason. Response: the major is insufficient. To it must be added: or it is a privation or negation of a real being. For Aristotle in the passage just cited places privations and negations among beings — which he would not do, Scotus adds in that place, unless negation and non-being possessed being in some manner.

Objection III. Affirmation and negation are treated by logic, which deals with beings of reason, and are acts of reason or intellect. Therefore if negation is a being of reason, so too is privation. Response: if affirmation and negation are taken for active acts of the intellect, they are real and belong to psychology; if they are taken for passive acts, they belong to logic and are beings of reason. But they also belong to privation independently of any intellectual operation — as night is, blindness is, a person is not a stone, a plant is not a lion — as the Doctor suggests (*1. d. 23. q. un. E*) and (*2. d. 12. q. 2. ante G*) and (*Quol. 19. q. de tertio Y*).

Article II. What Privation Is

The Canonist (*1. Phys. q. 10. art. 2*) and the Parisian (*ibid. q. de privatione prop. 2*) report that Thomas the Englishman thinks privation to be a real positive being; but the opposite is defended by Scotus (*1. d. 25. q. un. §. Item arguo H*) and (*in Rep. d. 28. q. 1*), Auriol (*2. d. 2. q. 2. art. 2*), John of Maisières (*1. Phys. q. 13*), Tatar (*ibid. q. 1. dub. 1*), and the rest, who deny that privation is anything real and positive.

Note I. Privation, properly taken, presents two aspects: one in the direct case or formal aspect, which is the absence of form; and another in the oblique case or material aspect, which is the subject apt and suited to receive the form. Through the first, privation and negation agree, because both are an absence of form; through the second, they differ from one another, since negation requires no suitable subject. Hence St. Augustine (*3. de lib. arb. c. 24*) adds: "Blindness in eyes newly born is not a defect, nor can it properly be called blindness" — so an

infant is not called imprudent, because it is not yet capable of prudence. Therefore in these cases there is negation of sight before the ninth day and the appropriate time; but afterward, if deprived of those forms, they are said to be deprived — so that the one is called blind, the other imprudent. And this is what the Doctor signifies (*1. d. 5. q. 2. §. Tertio principalius infra P*) and (*d. 28. q. 2. §. Quantum ad 1. B*) etc.

Note II. Being taken universally, insofar as it abstracts from the positive, the privative, and the negative, is equivocal, as the Canonist (*ibid.*) suggests and the Doctor in (*Rep. 1. d. 42. q. 2*), with whom Antonio Andrea (*4. Met. q. 2. §. Ad argumenta*) and John of Maisières (*1. Phys. ubi supra*) agree, accepting the division of real being into positive, privative, and negative. Hence real being is taken in two ways: in one way, improperly — so privation and negation are called real beings; in another way, properly — and so only positive being is real.

Assertion I. Privation is not a positive being. This is the position of the Doctor in the passages already cited. First proof: from Aristotle (*1. Phys. T. 75*), calling privation a non-being — that is, a non-positive being, as Antonio Andrea explains in the *Met.* passage cited, along with other interpreters. And in (*5. Met. cap. 22*): "Privation is the absence of form in a suitable subject" — as blindness is the privation of sight. But blindness in a blind person formally designates no positive entity. Therefore, according to Aristotle, privation is not a positive being. Second: privative opposites relate to one another such that one is positive and the other privative — as light and darkness, from the postpredicaments chapter on opposites. If privation were a positive being, there would be no opposition between them, for they would be positive, and they would be called habits rather than privation and habit, as privative opposition requires. Third: a created positive being is the terminus and object of a productive and factitive potency and of positive change; but privation is the terminus of corruption and destructive change. Fourth: evil is not a positive being, but the privation of good, as I showed in the Moral treatise (*1. 2. q. 2. art. 3*). But privation is evil, because through it matter contrives mischief — that is, the corruption of the form it possessed. Therefore privation formally presents nothing positive.

Assertion II. Privation is rightly called a privative being. This is the view of Scotus above, especially (*4. Met. with Arist. ibid. T. 2*), where Aristotle affirms that privations and negations are beings. But they are not positive beings, as I proved in the previous assertion; therefore they are privative beings. Hence the Doctor in the cited Reports explicitly says: "Of beings, some are positive, some privative." First proof: being is the participle of the verb of existence "sum, es, est." Privation, however, is like blindness in an eye deprived of sight — "and a blind man is one deprived of sight." For it is valid to say "the blind man exists," therefore "the blind man is an existing thing." But a blind man is not an existing thing except through blindness; and what is existing is a being, since existence is its mode. Therefore it is rightly concluded that privation is a privative being.

Second: the principle of natural generation is a being, because from it a natural composite comes to be. For "from nothing nothing comes to be" is the common maxim of the philosophers (*1. Phys. T. 33, 34*), as I have sufficiently discussed in this book, question I, article VI. Again, privation is the terminus from which of positive change (*5. Phys. T. 7*), as Scotus confirms (*4. d. 43. q. 3*), and it is one of the contrary principles (*1. Phys. T. 66*). Moreover, distinction is a property of being; but privation is distinguished from other principles and from other things that are not privation. Further, darkness, which is the privation of light, truly exists in dark air, and in (*Gen. 1*) is said to have been upon the face of the deep, and in (*Luc. 23*): "Darkness came over the whole earth." Therefore if privation exists and is said to have come to be, it is certainly a being — not a positive one, therefore a privative one, as Arriaga perceives (*disp. 2. sect. 12*).

Someone might say, with Mastri and his associate (*disp. 4. q. 1. art. 1*) following Hurtado (*disp. 3. sect. 12*), that it is self-contradictory for privation to be a real privative being, since a real being is the same as a positive being, which differs from non-being and from a being of reason. Furthermore, one could equally say that illness is a privative health, and sin is a privative justice. On the contrary, there appears rather to be a contradiction in saying that a real privation exists on the side of the thing — as they concede — while denying that it is a real privative being. For what exists in the nature of things independently of any intellectual operation, such as deafness in an ear and blindness in an eye, is a real being. The copula signifies such being as is its predicate, and the predicate is real privative; therefore it signifies real privative being. Hence when one asks whether there is a vacuum, it is equivalent to asking whether there is a place deprived of a body. Furthermore, common usage must be maintained, as the Major testifies (*1. Praedicabilium q. de proprio*). And the customary usage, both among the ancients and among moderns, is to call privations privative beings, as may be seen in Scotus cited, in Fuentes (*q. 3. diff. un. art. 1*), John of Maisières, the Parisian, and countless others. Nor does it help them to append the examples of health and illness, sin and injustice — for these are qualities, as is evident in the chapter on quality, which are positive beings agreeing univocally in the generic notion of quality; therefore one cannot say that illness is a privative health, nor that sin is a privative injustice, since both illness and injustice are positive beings placed in that predicament. Nor does it help what others add with Auriol (*2. d. 2. art. 2*), that it is better to say "form is not present" than "privation is present" — for instance, "light is not present" rather than "privation of light is present." For among everyone, the following locutions are admitted as true: "Night is," "death approaches," "darkness arises." Hence Augustine (*1. contra Manich. cap. 4*) writes: "Where light is not, there is darkness." And Damascus (*2. fid. cap. 7*) adds: "Darkness is not the substance of air, but the privation of light." The reason given is not incongruous: for things are thus understood and expressed as they are on the side of the thing; and such privations exist on the side of the thing — namely, night is the privation of light,

and blindness is the privation of sight. Therefore such expressions and locutions should not be dismissed.

Assertion III. Privation is the absence of form in a suitable subject. So Scotus (*1. d. 5. q. 2. infra P*) and elsewhere. First proof: from Aristotle (*5. Met. cap. 22*), who defines properly-taken privation in just this way, as stated above. Second: that is a correct and fitting definition in which genus and difference are present, or quasi-genus and quasi-difference in those things that cannot be exactly defined, such as privation. But the aforesaid definition has a quasi-genus — namely, absence of form, in which privation and negation agree — and a quasi-difference, indicated by the following words. Therefore it is well formulated. I add that it contains nothing superfluous and nothing deficient, which is required for an exact and genuine definition, as I have insisted not infrequently in the foregoing.

Objection I. Against the first assertion: what is created is a positive being, since it is the terminus of a positive production. But privations are created — as darkness, which is the privation of light, according to that passage (*Isa. 45*): "I, God, who made light and created darkness." Therefore privation is a real positive being. Confirmation: privations invite praise and blessing of the Lord, as is evident in the hymn of the three youths: "O light and darkness, bless the Lord." This therefore is a sign that they are positive beings. Response: I concede the major; I deny the minor. As to the testimony of Isaiah, Augustine responds (*q. 106 of the Old and New Testament*) that by light is to be understood heaven, and by darkness, earth — which is the same as Moses' statement in (*Gen. 1*): "In the beginning God created the heaven and the earth." It can also be explained as an improper and metaphorical creation, just as the praise and blessing attributed to them are interpreted metaphorically — which also explains the passage adduced in the confirmation, and that of (*Josh. 24*): "Behold, this stone shall be a witness to you, because it has heard all the words the Lord has spoken."

Objection II. A real positive effect proceeds from a real positive cause and principle; but to be set in motion, to become evil, to be corrupted, and the like are real positive effects proceeding from privation, as is evident from (*1. Phys. Tit. 80, 81*). Therefore privation is a real positive being. Confirmation: privation is perceived by the senses — for sight distinguishes darkness and light (*2. anima Tit. 138*). Therefore privation should not be removed from positive being. Response: I concede the major; I distinguish the minor. Per se — I deny; per accidens — I concede, as Aristotle explains there. The same distinction applies to the confirmation. For sight attains light per se and positively; darkness per accidens and negatively, insofar as it does not perceive light, whose absence is called darkness — just as silence is said to be where there is no sound, nakedness where there is no clothing, and void and emptiness where there is no body, as Augustine explains (*lib. de natura boni c. 16*) and (*contra epist. fundament. cap. 30 and 31 in fine*).

Objection III. What is nothing determines nothing; but privation determines a subject, which is why one sometimes says "the blind man walks" or "the blind man loves" — not because blindness is the reason for walking or loving, but because the subject in which such a privation resides is the subject of that predicate, that is, the subject is determined by that predicate, as the Doctor writes (*1. d. 23. q. un. infra H*). Therefore privation is a positive being.

Confirmation: privative opposites differ from contradictory opposites not by reason of the negation in which they agree as a genus; therefore they differ by reason of the other extreme, which is positive — and therefore privation formally implies the positive. Response: I concede the major; I distinguish the minor. Positively — I deny; privatively — I concede. For privation, beyond the absence of form, connotes a subject suited to receive the form of which it is deprived. Therefore actions are attributed to it by reason of what it connotes, as the Doctor excellently explains in the passage cited. To the confirmation: I say that contradictories differ from privatives in that the latter in one extreme designate the absence of form in a suitable subject — which is properly called privation — while the former designate the absence of form without any capacity of the subject of which they are predicated, as I noted in note I and the Doctor fully explains (*1. d. 28. q. 2. §. Quantum ad 1*).

Objection IV. Against the third assertion: St. Augustine (*lib. de natura et gratia, contra Pelagianos cap. 51*) teaches that through blindness the power of seeing is lost; therefore privation is not the absence of form in a suitable subject, since where there is no power, there is no aptitude. I deny the inference. For there can be aptitude in a subject to receive a form, even if there is no power in it to produce that form — just as in a suitably organized body there is aptitude and capacity to receive a soul, yet no power exists in it to create that soul and infuse it into the body. Or I distinguish the antecedent: the proximate power of seeing is lost — I concede; the remote and radical power — I deny. For this is inseparable from the subject in which it resides, since it is distinguished from it formally only.

Article III. How Many Kinds of Privation There Are

Some, who strip privation of all entity, consistently remove from it all plurality and distinction as well. Others, however, who grant privation some mode of being, concede it a corresponding unity, plurality, and distinction, in proportion to the unity and multiplicity of the opposed forms. For the understanding of this, what I said in the preceding question on the potency of matter (*art. 12*) and on its appetite (*ibid. art. 13*) is in some way helpful. It will now be useful to note a twofold privation: one remote or indeterminate, the other proximate and determinate. This is illustrated by example. Matter can receive in itself all forms other than the one it currently possesses, and since it does not have them, it is said to be deprived of them by a remote privation — since it cannot participate in them without prior dispositions by which it is, as it were, brought near to

them. Therefore it does not look to them proximately, because it looks indifferently and no more to one than to another. But when it is disposed and prepared by suitable qualities for the reception of some particular form, it is said to be brought near to that form and to acquire the proximate and determinate privation of that form rather than of another.

Assertion I. Privation is multiplied in proportion to the multiplication of opposed forms. The Doctor agrees (*2. d. 12. q. 2. §. Ad argumenta F*) and (*Quol. 18. §. Ex isto Y*). First proof: from Aristotle (*1. perih. cap. 5*), where the Philosopher holds that the number of negations is derived from the number of affirmations, which denote the positive forms to which their privations are immediately opposed, as Scotus notes (*2. d. 2. q. 1. §. Hic dicitur*) and (*q. 9. ante M*). Therefore privation is multiplied in proportion to the multiplication of opposed forms. Second: of opposites there is one science and one account (*1. Top. cap. 14*) and (*2. priorum sect. 3. cap. 1*). But privation and form are privative opposites, chapter on opposites. Therefore according to the multiplication of one, the other is multiplied. Third: there is no terminus toward which unless the terminus from which precedes it, as is clear in progressive motion. But privation is the terminus from which of natural change, and form is the terminus toward which; therefore when the latter is multiplied, the former is also multiplied — and so there are as many privations as there are opposed forms.

Assertion II. Privations differ from one another just as the habits or forms to which they are opposed. Scotus teaches this (*2. d. 37. §. Ex ista solutione E*) and (*Quol. 18. §. Ex isto Y*). First proof: that by which something is constituted is the same as that by which it is distinguished, for the constitutive principle and the distinguishing principle are the same (*1. d. 26. q. un.*). But privation is constituted by the absence of form in a subject capable of receiving it (*5. Met. cap. de privatione*). Therefore it is distinguished primarily from the form opposed to it. And just as that form has its quasi-species and individuals — as is evident in the elemental and mixed forms, and in the vegetative, sensitive, and intellective souls — so privation in its own way acquires its species and individuals: thus deafness and blindness differ from one another as quasi-specifically, and this deafness from that deafness, and this blindness from that blindness, as quasi-numerically distinct. Second: a shadow follows an opaque body in relation to the light of the sun or another luminous body; therefore just as a body acquires its specific positive difference, so a shadow has its specific privative difference — and thus this body and this shadow share a numerical difference. Third: a being of reason does not lack its own species and individuals, just as the positive being on which it is founded does not. Likewise, therefore, a privative being, which is privation, is not deprived of its privative species and individuals. I add that opposites are adequate to one another — as is especially evident with contraries — and one is placed in the definition of the other in the oblique case; and these are recognized through and reduced to their positive opposites, as Antonio

Andrea observes with Scotus (*4. Met. q. 2. §. Ad argumenta*). Therefore one must philosophize in like manner regarding the distinction of privations as of forms.

Objection I. Against the first assertion: Aristotle (*1. Phys. Tit. 79*) makes privation one in number with matter. Therefore, according to Aristotle, privation is not multiplied in proportion to the multiplication of forms. Confirmation I: there is one potency numerically in matter for all forms; therefore there is also one privation of all forms. Confirmation II: one relation can be directed toward several terms; therefore also one privation toward several forms. Response: I distinguish and explain the text already cited. Privation and matter are one in number subjectively — I concede; formally and intrinsically — I deny. To Confirmation I: I distinguish the antecedent. In species — I concede; in number — I deny. For there are as many numerically distinct potencies in matter as there are forms receivable in it, as the Doctor teaches (*1. d. 1. q. 1. §. Ad 1. G*). To Confirmation II: I deny the antecedent. For relations are multiplied in proportion to the multiplication of their terms, as I proved in Logic (*lib. 3. q. 6. art. 7*).

Objection II. Many privations can be opposed to just one form — as many kinds of darkness are opposed to the light of the sun, by which not only they but also other kinds opposed to the light of fire and other luminous bodies are dispelled. Therefore it is not necessary for privations to be multiplied in proportion to the multiplication of forms. Confirmation: in moral matters, extreme vices, which are privations of virtue, are opposed to one single habit of virtue — as prodigality and avarice are opposed to liberality. Therefore, analogously, in natural things many privations can be opposed to one form alone; and thus, without form being multiplied, privations can be multiplied. Response: I deny the antecedent, since there are as many kinds of darkness as there are lights opposed to them. For the light of the sun is one thing, that of fire another, and so on with the other luminous things, which differ in species. To the confirmation: I deny the antecedent, for there are several formally distinct virtues because there are several formally distinct objects, and diverse rules and teachings are given about them, as Scotus suggests (*2. d. 17. q. 2*) and (*3. d. 36. q. un.*).

Objection III. Against the second assertion: what differs in species or number is placed in the predicaments, which are a series of genera, species, and singulars; but no privations reside in the predicaments, since these are positive beings, while privations are privative beings. Therefore no specific or numerical distinction is to be sought in them, as in those opposed forms. Response: I distinguish the major. What differs positively — I concede; privatively — I deny. Especially because privations are reduced to the categories in which the habits opposed to them are placed, just as shadows are reduced to the bodies whose shadows they are.

Article IV. Whether Privation Is Distinct from Matter

Earlier philosophers, as Aristotle notes (*1. Phys. T. 79*), make privation and matter one; later philosophers, however, together with the same Aristotle there, distinguish privation from matter.

Note that distinction is a property of being (*4. Met. cap. 1*) and (*5. eiusdem, cap. 9*), and does not extend further than its subject, which is being. Now since being is divided by Scotus (*in Rep. 1. d. 42. q. 2*) into positive and privative, it follows that between real positive beings there is a real positive distinction; and between positive being and privative being there is a real privative or negative distinction, as the Canonist notes (*1. Phys. q. 1. art. 4*), followed by Ruvio (*Tract. 3. de privatione, ad finem q. 3*).

Assertion. Privation is really and negatively distinct from matter. The assertion is twofold and agrees with Scotus (*2. d. 12. q. 1*) and (*4. Met. Tit. 2*) and (*12. eiusdem Tit. 12*), and is explicitly defended by the Canonist (*ubi supra*), Tatar (*ibid. q. 1. dub. 2*), and the Parisian (*q. 1. de privatione, prop. 3. fol. 25*). The first part is proved, first: those of which one remains while the other does not are really distinct, as Scotus explains (*2. d. 1. q. 4. §. contra istam*). But matter always remains, being ungenerable and incorruptible (*1. Phys. T. 82*), while privation departs when form arrives (*ibid. Tit. 60*). Therefore privation really differs from matter. Second: a subject and what is in the subject are really distinguished, as is evident with an accident, which is in a substance, and a soul, which is in a body. But privation is in matter, which is their common subject and that of form. Therefore privation and matter are really distinct. Furthermore, privation is the cause of mischief or corruption of the composite (*1. Phys. T. 81*), and is the terminus from which of generation and a non-being; but matter is a substance, an essential part of the composite, the receptacle of all forms — and these and similar things argue a real distinction between the one and the other. Moreover, if matter possessed all forms, there would be no privation in it; therefore a distinction falls between them, since an evident sign of real distinction is the separation of one from the other. And this is signified by Aristotle in the postpredicaments, where he warns that to be blind and blindness are not the same. For a person is blind, but blindness is the privation of sight. Therefore matter and the privation residing in it are really distinct. The second part is shown against Arretinus (*1. Phys. in annot. q. 21*): between two real positive beings there is a real positive distinction, as between Peter and John; therefore between a positive being — such as matter — and a privative being — such as privation — there intervenes a real privative or negative distinction. Furthermore, they are called privative opposites, taking the denomination from the one extreme that is only privative, even though the other is positive; therefore likewise the distinction between matter and privation is called negative, because privation is a privative or negative being. Moreover, distinction — from what was noted above — is a property of being; therefore, such as the being is, such is the

distinction. But privation is a privative being; therefore between it and matter there intervenes a privative or negative distinction.

Objection I. Privation and matter are distinguished by the same distinction as form and matter; but the latter differ from one another by reason alone. Therefore so do the former. The major holds by parity, because each is a distinct principle receivable in matter. The minor is supported by the authority of the Philosopher (*1. Phys. T. 60*), who says that form and matter differ by reason. Response: I concede the major; I deny the minor. As to the testimony of Aristotle, I say it must be interpreted as meaning by "reason" the essence and definition, not merely the operation of the intellect, as he indicates (*ibid. T. 29*) and in the antepredicaments, where he plainly teaches that the reason of univocals is the same — that is, their essence and quiddity.

Objection II. Distinction is a property of being and a real relation, as I noted above; but privation is not a real being. Therefore between it and matter there is no real distinction. Response: I concede the major; I distinguish the minor. It is not a real positive being — I concede; it is not a real privative being — I deny. Therefore between matter and privation there falls a real negative distinction.

Objection III. By no power, not even by God's absolute power, can matter exist without privation, since matter cannot receive in itself all possible forms — especially those that are simultaneously incompatible — therefore between them there is no real distinction, which falls between what can be separated from one another at least by divine power. Response: even if this holds collectively, it does not hold distributively — just as integral parts are really distinct from one another, and each can be individually separated from the others, even if not all simultaneously, since otherwise the whole constituted from them would be destroyed. Or one may say this arises not from the side of matter, which is capable of all things as far as it itself is concerned, but from the side of the simultaneous incompatibility of those forms, as the Doctor hints (*2. d. 12. q. 1. F*). Someone might say: matter, setting aside everything that is not itself, is deprived of form; therefore in its own essence it includes privation, and consequently privation does not differ from matter. Response: I distinguish the antecedent with the Canonist cited: formally — I deny; fundamentally — I concede. Just as being precisely and formally is neither finite nor infinite, but fundamentally and radically it is, above all because being is the foundation and origin from which finitude and infinity proceed — so matter in itself and in its essence does not formally include privation, yet by reason of the appetite it has for forms it is the root and foundation from which privation emanates, and in which it is grounded and resides.

Article V. Whether Privation Is Truly a Principle of Natural Generation, and in What Sense

Plato denies this, according to Aristotle (*1. Phys. Tit. 80*), from whom the Nominalists do not appear to depart, according to the Parisian (*q. 1. de privatione fol. 24*), who make privation and matter into one principle alone. Aristotle affirms it in the passage just cited, along with his commentators there, establishing privation as a second principle of natural change and distinguishing it from matter and form, which are the remaining principles of the same natural generation.

Note I. Recall from what has been said that privation is indeed a principle of things in their becoming, but not in their being already made. That is to say: it is a principle of generation as a terminus from which and by way of origin, as Tatar rightly explains (*1. Phys. cap. 3. q. 1. dub. 1*). It is not, however, a principle of composition, since only matter and form enter into the composition of the whole as its essential and quidditative parts. Furthermore, it must not be passed over that "principle" has a wider extension than "cause." For a cause has influence upon an effect, but it is not necessary that a principle furnish influence upon what is principiated — it suffices that it be prior to what proceeds from it; so that the precise notion of a principle is to be prior to that of which it is the principle, as is clear of the point that initiates a line, contributing nothing to it, and of the terminus from which of a motion, which is its principle while contributing nothing to the motion itself.

Note II. From Scotus (*2. d. 1. q. 2. §. Respondeo Ad A*), priority is twofold: of duration and of nature. Priority of duration belongs to what precedes another in time, as Adam is prior in time to Abel. Priority of nature is twofold: positive and negative. The positive priority is that by which one thing precedes another in act and is placed first in the order of things — as animal is positively prior in nature to rational, and rational is prior to risible, and in general a cause is prior to its effect. The negative priority is that which belongs to what would truly have preceded another, had it not been impeded by an agent — as at the beginning of the world, privation would have been in matter before form, had not God co-produced and co-created form in it. The Doctor says the same (*q. 3. §. Tenentes autem H*) and (*in Rep. q. 3. §. Ad q. dico*) and (*q. 4. §. prima istarum in solutione 3*).

Note III. From the same Doctor (*3. d. 2. q. 3. §. Ad rationes E*) and (*d. 7. q. 2. §. Ad argumenta E*) and more clearly (*in Rep. 3. d. 3. q. 3. in fine*), change is taken in two ways: broadly and strictly. In the first way, it is taken for any transition of a thing whatsoever — so creation is called a change (*2. d. 1. q. 5. §. Secundum T*) and (*4. d. 10. q. 1. §. Quantum G*) — the new presence of Christ's body in the Eucharist is called a change, and (*1. d. 39. §. Ad 1. argumentum 3. q. 5*) progression from one contradictory to another is also called a change. In the second way, strictly, it is taken for a transition from the privation of form in matter to the form itself — so matter is changed because it goes from not having form to having it, and is otherwise now than before, as the proper notion of change given by Aristotle (*5. Phys. T. 7*) and accepted by Scotus in the places cited and explained by Lychetus

(*ibid.*) and (2. d. 2. q. §. *Respondeo ad 1. contra*) demands. Therefore change properly requires that privation temporally precede form in matter, and that form's arrival cause privation's recession, and that matter be changed from privation of form to form. Since two privative opposites cannot simultaneously be in the same subject, it follows that privation is first and form is afterward, as the Doctor says (3. d. 7. q. 2. E) and (4. d. 43. q. 5. §. *De tertio H*), and Bassolis agrees (3. d. 7. q. un. q. *Ad 1. in oppositum*). By this twofold acceptance of change, Mastri and Poncius can be brought into harmony. For Mastri (*disp. 4. q. 3*) holds that privation is a principle of natural generation insofar as it temporally precedes form in matter; while Poncius (*q. 1. de privatione disp. 34*) holds it sufficient that privation precede by nature, if not positively, at least negatively. They can be reconciled, I say, if we hold that Poncius is speaking of change taken improperly — that is, generation as production — in which sense privation is required only to precede by nature privatively or negatively, as when the generation of fire had been from eternity, and as in the generation of things at the beginning of the world, in which forms of the heavens, elements, and mixed things were produced simultaneously in time with matter; and as in the worm generated through the corruption of the Eucharist, a new matter with form produced by God in an instant in which privation precedes only by nature. And this is all that is proved by the arguments that Poncius accumulates there. Mastri, however, speaks of change taken properly, and of generation as change, not merely as production, as he himself explains there. Nor do the authorities and reasons he accumulates prove anything else. For proper change does not occur unless the subject is otherwise now than before, through the reception of a new form of which it was previously lacking. And so the dispute seems to be one over a name rather than a thing, in which the common usage of authors is to be maintained, as I noted elsewhere.

Assertion I. Privation is a per se principle of natural generation. So Aristotle (1. *Phys. T. 67, 79*) and (12. *Met. T. 12, 22*), and Scotus in the commentary there. First proof: a per se principle of something is that from which something arises and begins, as is clear from note I above. But natural generation arises from non-being, which is privation — as a horse comes from what is not a horse, and a human from what is not human, as the Philosopher argues against the ancients in the passage cited. Therefore privation is a per se principle of natural generation. Second: natural change requires two termini — a terminus from which and a terminus toward which; the first is where it begins, the second where it ends. But the former is privation (5. *Phys. T. 7*), and the latter is form. Third: when air passes from darkness to light, the principle and terminus from which is not the air, because it is the subject; nor is it the form to be expelled, because the agent does not per se intend to expel it, but to introduce a new form — and if the preceding form were to persist, no new generation would arise from it. Therefore the terminus from which, or the principle, is established to be darkness, which is the privation of light.

Someone might say privation is a per accidens principle (*1. Phys. Tit. 81*). The Doctor responds in the commentary (*12. Met. T. 12*) that privation is a per accidens principle of the thing generated, because it neither exists nor remains in it; but it is a per se principle of generation, because generation begins from it, as a line from a point and local motion from its terminus from which.

Assertion II. Privation temporally precedes form in matter before that form is drawn or introduced from it by generation. So the Doctor (*3. d. 7. q. 2. E*) and (*4. d. 43. q. 5. H*) after Aristotle (*1. Phys. T. 43, 44*). First proof: a natural agent does not act instantaneously but successively, since it is of finite and limited power. For it first disposes and prepares the subject with prior and suitable qualities, then expels the former form so as to introduce a new form into the same subject — and this entire progression takes place in time. For there is a transition from privation to form; therefore privation in matter temporally precedes form. Second: natural generation is a change between opposed termini, of which one is called privation and the other habit or form. But these termini cannot simultaneously coexist in the same subject. It is impossible that non-form, or privation, and the form that is opposed to privation, should simultaneously be in the same subject — just as it is impossible for contradictories to be simultaneously in the same subject and said of the same subject, so that the same thing is and is not at the same time. And privative opposites repugn one another as much as contradictories do, although the latter are wider and more extensive than the former, as the Doctor rightly notes (*in Rep. 2. d. 1. q. 6. in fine*).

Someone might say that privation naturally precedes form, so that in the first instant of nature there is privation, and in the second instant of nature there is form — both, however, at the same and identical moment of time. And this becomes especially clear because generation is an instantaneous change, in which way there is no repugnance or contradiction between the aforesaid opposites, since they are distinct signs of nature, which suffice to remove contradiction. On the contrary: such signs of nature, even if sufficient for conceiving and prescinding one from another, are not sufficient for dividing them. For I can conceive of the sun without light and a human without risibility; but I cannot rightly separate the sun from light and a human from risibility, nor deny that the sun is luminous and a human risible; nor can I simultaneously say in the same instant of time that the sun is not luminous and is luminous, that a human is not risible and is risible, because these mutually contradict one another. Analogously in our matter: in the same instant of time, form and its privation cannot coexist, otherwise the same form would simultaneously be with its privation and not be — and so contradictories would coexist, as the Doctor argues (*3. d. 3. q. 1. E*). Furthermore, generation is called instantaneous when understood only as the introduction of form into matter, not as the entire progression required for it, as I showed in the book on generation. Third: one must philosophize in nearly the same way about artificial form and its privation as about natural form and its privation, as Aristotle repeatedly notes, especially

(1. *Phys. Tit.* 69) and (12. *Met. Tit.* 12). But the privation of artificial form in a subject precedes the form itself. For before the form of Mercury is fashioned from wood, in the wood itself the absence of that form precedes — and previously it was true to say that the wood does not have the aforesaid figure and form. Therefore, by analogy, privation preexists in matter before the agent draws from it the form opposed to that privation; and consequently privative opposites are successively grounded in matter, and in generation privation is temporally prior to form.

Assertion III. Privation initiates after the manner of a terminus from which and by way of origin — which others call "through its own non-being." This is drawn from Scotus (12. *Met. in com. Tit.* 11 and 12) and (2. *d. 1. §. Secundum T*) and (4. *d. 11. q. 1. §. Dico ergo E*). First proof: privation initiates when form is drawn from the potency of matter, because generation then begins, and generation cannot be initiated without a principle. But when form is drawn from the potency of matter, privation no longer exists, because it yields to the arriving form, as darkness flees when light comes. Therefore privation initiates by way of origin, or through its own non-being. Second: privative opposites do not coexist in the same subject simultaneously — for one is the negation of the other in a suitable subject. But when generation arises through the power of an extrinsic agent, privation does not remain, because form, with which it cannot coexist, arrives; and when form arrives, privation recedes — just as the terminus from which perishes in motion through the acquisition of the terminus toward which, to which the former is opposed. Third: the terminus from which of creation — which is nothing, or negation outside the genus — when a thing is created does not exist, because nothing and a thing cannot simultaneously be. Therefore, just as when the creation of a thing begins its negation no longer exists, so when a thing is generated, privation escapes, driven out by its contrary, which is form — and thus privation is established as a principle of generation through its own non-being and by way of origin.

Objection I. Against the first assertion: principles are those from which all natural things come to be (1. *Phys. T.* 42). But nothing comes to be from privation, because privation is a non-being (*ibid. Tit.* 75), and from non-being nothing comes to be, since non-being is nothing, and "from nothing nothing comes to be" is the common maxim of the philosophers there (*Tit.* 33). Therefore privation is not a principle of natural generation. Confirmation I: a principle is more noble than what is principiated, just as a cause is nobler than its effect (3. *anima T.* 19), as cited by the Doctor (1. *d. 3. q. 7*) and (4. *d. 44. q. 2*). But privation is not more excellent than the composite, which is the principiated, since the composite is a real positive being while privation is a real privative being. Confirmation II: a principle produces and has influence upon what is principiated, which is produced by it. But privation does not produce but corrupts, does not construct but destroys what is produced, since it is the cause of corruption of natural things (1. *Phys. T.* 81). Therefore privation is not to be

numbered among the principles. Response: I concede the major; I distinguish the minor. As the terminus from which of generation — I deny; as an intrinsic part of composition — I concede. For just as the terminus from which of creation is nothing or negation outside the genus, so the terminus from which of natural generation is privation or negation in the genus; and something comes to be from privation as from a terminus from which, physically. But from negation outside the genus or from nothing, nothing comes to be naturally, as I explained at length (*lib. 2. q. 1. art. 6*). To Confirmation I: I distinguish the major. Absolutely and universally — I deny; in a qualified and indefinite sense — I concede. As matter, which causes the composite partially, is nobler in a qualified sense and in the notion of a principle — but absolutely and simply, the composite is more excellent than it, as a whole is more excellent than its part. To Confirmation II: I distinguish the major. Principle of composition and of being already made — I concede; principle of generation and of becoming, which is what privation is — I deny. Just as I explained of the point that is the principle of a line while contributing nothing to the line itself, in note I. To the minor: I say, with Aristotle there and Scotus (*2. d. 12. q. 1. I*), that this is per accidens — not with respect to the thing to be produced, of which privation is the principle, but with respect to the thing produced, of which it has no character of principle.

Objection II. Against the second assertion: Aristotle (*7. Phys. T. 1*), (*5. eiusdem*), and also (*1. Caeli T. 103*) establishes that motion, time, and other created things have existed from eternity. And Scotus (*2. d. 1. q. 3*) defends as a problem that the world could have been created by God from eternity. On that hypothesis, the generations of things would have existed from eternity. But in eternal things there is no before or after in duration. Therefore in matter, privation would not have preceded form — and thus for generation to occur, it is not necessary that privation temporally precede form. Confirmation: generation is a momentary change, just as illumination is (*2. d. 2. q. 9. sub L*). But in it there are always required two termini — from which and toward which — without any priority or posteriority of duration, just as a relation requires two extremes naturally simultaneously existing, from which it emerges. Therefore privation need not preexist before form. Response: even if in this and certain other matters the Philosopher erred, nonetheless on that hypothesis the production or generation would not be a proper change but an improper one. Therefore it does not require privation to precede positively but only negatively, as was made clear with Scotus in note III above. By the same reasoning the confirmation is answered: generation, insofar as it is not properly a change but only a production, does not require privation preceding in matter positively but only negatively. Therefore between privation and form to be received in matter no temporal interval intervenes.

Objection III. Against the third assertion: action is not without an agent, therefore neither is initiation without a principle and initiator. Therefore, just as

a cause in act has its effect in act (*2. Phys. T. 38*), so a principle in act has what is principiated in act and vice versa; therefore if privation initiates, it initiates through its own actual being. Confirmation I: privation initiates when it is expelled by form; but at that point privation exists, because what is expelled and the expelling thing must simultaneously exist. Confirmation II: privation is deemed a principle as the terminus from which of generation; but the terminus from which exists when something proceeds from it, as is clear of one who travels from one city to another. Confirmation III: from (*4. Met. T. 22*), that which casts away retains something of what is cast away; likewise, therefore, when privation is cast away, something of it remains which exists, and therefore it initiates through its own existing being. Response: the argument concludes only about a principle that has real influence upon what is principiated, and about a principle that is intrinsic, constitutive, and permanent in what is principiated — but not about a principle that causes nothing in what is principiated, that is extrinsic, that departs and recedes from the subject and the principiated, as the Canonist suggests (*1. Phys. q. 10. art. 3*), after Aristotle (*1. Phys. T. 68, 60, 61*). To Confirmation I: I say this holds in the case of an effective collision and conflict of contrary opposites, as with heat and cold which mutually expel one another from the same subject — but not with privative opposites, of which one is said to expel the other through its own being posited: so when form is posited in matter, privation departs — just as when light comes, darkness is driven out, not by any efficient action of light against darkness, but by the sole position and presence of light, by which darkness is expelled, having been immediately before that light in the air. To Confirmation II: I concede the major; I distinguish the minor. About a terminus from which that remains, as illustrated in the example — I concede; about a terminus from which that departs and recedes, as privation does — I deny. And this is clear from night, which vanishes as day approaches. To Confirmation III: I say with Scotus in the commentary there that this passage is to be understood of things that are moved and changed, of which some parts persist — as matter — and others cease to be — as form. Or of things capable of intension and remission, of which some parts grow and others diminish — from which arose the opinion of Heraclitus and others who held that all sensible things are in continuous motion.

Article VI. Whether There Is a Return from Privation to Habit

Aristotle in the postpredicaments, chapter on opposites, pronounces this saying, frequent on the lips of the Peripatetics: "from privation to habit there is no return." This is variously explained and illustrated by various interpreters, as may be seen in the Coimbricans (*ibid. q. un. art. 5*). Bassolis however notes (*4. d. 43. q. 2. art. 2*) that this was proved by the Philosopher but not demonstrated, since it is proposed not universally but indefinitely, as Antonio Andrea in the exposition of that passage and Scotus (*8. Met. in cap. 5*) indicate. Just as "principles are contraries" (*1. Phys. T. 41, 42*) is indefinite — meaning not all

principles are contraries, such as matter which receives contraries, but form and privation (*ibid.* T. 67) — so likewise in our matter, sometimes there is a return from privation to habit, as from darkness to light; and sometimes there is not, as from death to life. Therefore the aforesaid maxim is not universally true.

To clarify in which cases it is true and in which it is false, I observe with Scotus in the passage cited and (*q. 41. praedicam.*) that the form which is opposed to privation either proceeds from an intrinsic principle and is innate and congenital to the thing — as sight in a human, the privation of which is blindness — and in this and similar cases the Philosopher's saying is true, that from privation to habit there is no return, which is illustrated by the cited example of blindness and sight, and of baldness and hair, in which cases there is no recovery. Or the form arises from an extrinsic principle — as light from the sun in the air — in which way dark air becomes luminous and passes from privation to habit through the illuminating action of the sun. And such a return is possible: the reason is that an extrinsic agent, when it ceases to operate in a subject capable of the form induced by it, deprives the subject of that form, and the subject is said to be deprived. But if the same agent again approaches and operates upon the said subject, it restores the same form to it — in this way there is a return from privation to habit, as from darkness to light. In the former cases, however, the contrary occurs: because in the catalogue of natural things, no agent is found capable of repairing in a subject a form once lost there, as no one can restore to a person deprived of life the life of which he has been stripped. Therefore in these cases, from privation to habit there is no return. Others add — among whom is Antonio Andrea — that the latter privations deprive subjects of forms both actually and potentially in which they exist, whereas the former deprive them of forms only actually; therefore to the latter recovery is impossible by the forces of nature, while to the former it is possible.

I further note a twofold return: immediate and mediate. The first is when one thing is turned by a single change into what it was previously — as when water becomes air and immediately from air water returns; and when waking becomes sleep and from sleep waking returns. The second is when, through many changes of things, what previously existed returns — as (*2. Post. cap. 7. T. 15*): from rain falling on the earth vapors arise, from vapors clouds are born, and from clouds rain returns. The same is suggested by Augustine (*6. de Genesi ad lit. cap. 13*) and (*lib. de spiritu et anima cap. 15*), and Scotus in the Met. passage cited. But each kind of return is not to the same thing in number, but to the same in species (*2. de gen. T. 70. in fine*). By divine power, however, a return to the same thing in number is possible — (*Ioan. 11*): Lazarus, who had been dead, came back to life at the voice of Christ the Lord calling him: "Lazarus, come forth."

Against the teaching just presented, certain authors such as the Coimbricans cited above object: first, coldness is a form congenital and co-created with water; but if it is removed from water, when left to itself the coldness returns to it, as is

clear with heated water, which afterward returns to its original coldness. Therefore the said teaching is not true. Granted the major. To the minor: I say that heated water is actually deprived of coldness, but not potentially. Therefore when left to itself and with heat expelled, it returns to its native coldness. Hence the teaching in question holds for privation that deprives both actually and potentially, but not for privation that deprives only actually. For this reason the Philosopher uses the example of blindness, which deprives a person of sight both actually and potentially, as Augustine explicitly teaches (*l. de natura et gratia, contra Pelagianos c. 51*): "through blindness the power of seeing is lost."

Second objection: privation and form are two principles of natural change (*1. Phys. T. 67*), and hence also two termini of the same (*5. Phys. T. 7*). The terminus from which is privation, and the terminus toward which is form. Therefore since there is a change to these termini, it follows that there can be a return from privation to habit. Response: that proposition is not universal but indefinite, as I noted just above at the beginning of this article. Therefore in some cases it is accepted, in others rejected, as I made clear with the examples cited above, confirmed by authority and reason.

Third objection: one of two contraries includes privatively the opposite of the other (*10. Met. T. 15, 16*). But between contraries there is a change, as from heat to cold and vice versa; therefore also between privative opposites. Response: in the present theme and proposition under discussion, the Philosopher is speaking of a perfect privation, which belongs to one extreme in relation to the other extreme that is form — not of an imperfect privation, which belongs to one imperfect contrary, such as black, which in relation to white is said to be deprived of some perfection that white possesses, as Scotus rightly notes in the proximate *Met.* passage cited. Or one may say that this does not occur precisely by reason of privation but by reason of the contrary joined to it. Or one may deny the parity. For the change of contraries always occurs with motion properly so called and in time; but not always so with privative opposites, as is clear with illumination, which occurs in an instant (*2. anima T. 70*).

Question IV. On Form

Form occupies the third place among the principles. For although it is prior in order of dignity, it is nonetheless posterior in order of generation to privation. For since privation and form are contraries, they consequently require and presuppose their common subject — matter, which is the first principle; then follows privation, the second principle, which is the terminus from which of generation; and afterward form, the third principle, which is the terminus toward which of the same — its formal and principal terminus — about which it now remains to speak last.

Article I. Whether There Is a Substantial Form

Among the ancient philosophers, hardly any are found who acknowledge substantial form, as is clear from (*1. Met. sum. 2. cap. 1*). After Aristotle, however, the affirmative position so prevailed in the schools regarding substantial form that it is not an uncertain and non-evident dogma — indeed, the opposite is deemed erroneous, as Scotus writes (*in com. 7. Met. sum. 2. cap. 1*).

Note I. Because of the diverse and excellent functions form performs, it receives many names and epithets. First, it is called "one," because it draws indifferent and indeterminate matter to a determinate and fixed species, and chiefly constitutes what is one per se — namely the composite. Then it is called "species," both because it specifies matter and because it renders it beautiful and fair; for this reason Augustine writes that species and form coincide (*lib. de vera religione cap. 18*). And Aristotle had not unreasonably prefaced this: "Matter desires form as the ugly desires the beautiful" (*1. Phys. T. 81*). Furthermore, it is called "ratio," because from it especially the definition of natural things is derived; in this sense it is sometimes also called "what a thing is" and "quiddity." Besides, it is called "exemplar, light, character, act, entelechy, end, terminus," and the like — by which it is wondrously adorned and illustrated.

Note II. Form is divided into natural and artificial (*1. Phys. T. 69*): the latter is produced by art, while the former is drawn by nature from the potency of matter. Natural form is subdivided into substantial and accidental (*7. Met. Tit. 7 and elsewhere*), as Scotus expresses (*4. d. 11. q. 3. §. Alij Y. AA*). The former is a being simply and a primary act that together with matter constitutes what is one per se; the latter is a being in a qualified sense and a secondary act that together with its subject makes what is one per accidens. Furthermore, substantial form is subdivided into assisting and informing, as Aristotle indicates (*1. de partibus cap. 1*): the assisting form moves its subject from without by directing it, as a sailor steers a ship and a charioteer a chariot. The informing form moves from within the subject in which it exists, as the soul moves the body it informs. Finally, the informing form is divided into one conjoined with and inseparable from matter — as the form of a horse — and one separable from matter — as the rational soul, of which the Philosopher makes mention (*3. anima T. 19*).

Assertion. Substantial form exists. So Scotus as cited, after Aristotle (*1. Phys. T. 65*) and frequently elsewhere. First proof: from matter and form as two substantial parts there coalesces what is one per se substantially — namely the whole. Therefore form is a partial substance. The antecedent is clear from (*8. Met. T. 2*); the consequent holds from (*1. Phys. T. 51*): "From non-substance no substance comes to be" — that is, as intrinsic parts and principles constituting what is one per se, the substantial composite. But if every form were an accident, it would produce what is one per accidens — since from a subject and an accident what is one per accidens arises (*7. Met. Tit. 16*). Second: natural things differ in species from one another — as a human and a brute. But this specific difference is not derived from matter, which is common to both; therefore it is

derived from form, which is certainly a substance just as matter is — indeed, substance is more properly derived from it (*7. Met. Tit. S*), and it is more "nature" (*2. Phys. Tit. 12*). Third: substantial changes occur — as fire is transformed into air, air into water, and so with the rest; and perpetual substantial generations are observed. "The sun and the human generate the human" (*2. Phys. T. 26*). And there are the continuous corruptions of sublunary things, especially at the sun's retreat, as is clear with herbs, plants, and animals generated from putrid matter. But these do not occur without the production of new substantial forms and the perishing of the old ones. For since matter is ungenerated and incorrupt (*1. Phys. T. 82*) and the substantial whole is produced — certainly the substantial whole is not produced anew unless some substantial part of it is produced, namely form, which passes from non-being to being. Furthermore: diverse operations proceeding from diverse agents argue for their diverse substantial forms — for forms are known chiefly through their sensible operations, as Scotus teaches (*7. Met. q. 6. ad finem*) and (*q. 20. §. contra movens*). For just as matter becomes known to us through change, so form becomes known through operation. Someone might say: to save all this, accidental forms suffice. For it is clear that fire heats through heat, and water cools through coldness, which are accidental forms. Therefore no argument compels us to introduce substantial form into the schools. On the contrary: fire ignites not through heat — since through heat it only heats — but through an ignitive principle, which is its substantial form. Likewise water produces water, not coldness which is an accident, but through its own substantial form. For if water is heated and boils and loses its coldness, when left to itself it returns to its native coldness — not through coldness which was removed by the heat residing in it, nor through matter which is passive; therefore through an intrinsic principle, which is its substantial form. Finally, it has been established by faith in the Council of the Lateran under Leo X (*sess. 8*) and in Vienne under Clement V, as is read in the Clementine constitution on the supreme Trinity (§. 2), that the rational soul is the substantial form of a human. Therefore the same must be affirmed of the remaining souls and forms, both of elements and of mixed things.

Objection I. The motives of the ancient philosophers, touched on by Aristotle (*1. Met. sum. 2. cap. 1*) and explicitly treated by the subtle Doctor there in the commentary, by which they were moved to deny substantial form and to admit only one primary principle of all natural things, which is matter, are: first, matter is that from which all natural things come to be; second, all things are resolved into matter; third, from it per se and primarily all things come to be; fourth, matter alone remains while the others begin and cease to be. Therefore, besides matter, there is no substance that serves as a principle of natural things, and if there is any form, it is accidental. Response: the aforesaid arguments show that matter is the first principle of natural things, the primary subject of forms, that it enters into their essence, that they are at last resolved into it, and that it endures perpetually. All this we indeed admit. But we reject the claim that

it is the sole substantial principle, and we establish a substantial form from which, together with matter, the substantial whole coalesces as from intrinsic and essential parts.

Objection II. Aristotle (*2. de gen. cap. 7, 8*) writes that the forms of the elements are the primary qualities, which are accidental forms. Therefore the same must be affirmed of the forms of mixed things, since the reasoning is equally valid in both cases. Confirmation: the same Philosopher frequently compares natural things with artificial ones, as is clear (*1. Phys. Tit. 69*), (*2. eiusdem, Tit. 35*), (*7. Met. T. 26*), and (*8. eiusdem T. 15*). But the forms of artificial things are accidental; therefore so also are those of natural things. Response: the Philosopher speaks there by circumlocution, taking the qualities or properties of elements for their substantial forms, because the latter are hidden from us while the former are manifest. The same is done in (*5. Met. Tit. 18*), where quantity is defined through divisibility, which is its property. To the confirmation: I say the parity consists in this, that just as an artisan draws artificial forms from a preexisting and presupposed subject, so a natural agent draws natural forms from the potency of matter. In the rest there is a disparity — especially because natural forms are substances, while artificial ones are accidents, as will be more clearly apparent in the following book.

Objection III. Every substance exists and subsists per se. For this term "substance" is derived from subsisting per se, as I said in the Epitome (*dia. lib. 1. q. 4. art. 3. ante n. 10*). But a form drawn from the potency of matter does not exist or subsist per se, because it depends upon matter both in its becoming and in its being, as is clear from the soul of a dog, a lion, and the rest. Therefore no substantial form is found. Confirmation: substance is not in a subject, as Aristotle teaches in the antepredicaments. But every form is in a subject — namely in matter, which is its primary subject (*1. Phys. T. 82*). Therefore no substantial form exists. Response: I concede the major; I distinguish the minor. Actually — I concede; potentially — I deny. For even though a form drawn from the potency of matter actually enjoys the company of the matter that is its partner, it can nonetheless by divine power be separated from it and, thus separated, exist by itself, as Scotus teaches (*2. d. 12. q. 2. in fine*). To the confirmation: I concede the major; I distinguish the minor. Through inherence — I deny; through information, as a part exists in its counterpart — I concede. As is clear from second and universal substances, which are in first and singular substances through inexistence, not through inherence, which belongs to accidents.

Article II. What Form Is

There is not one definition of form held by all. Plato defines it thus: "Form is the image of a divine exemplar impressed upon things." The Arabs: "A participation of the first act, or of God, impressed upon things." Porretan in the book of the Six Principles, cap. I: "Form is what is contingent to composition, consisting of

simple and invariable essence." Aristotle (*2. Phys. Tit. 28*): "Form is the account of quiddity and essence." The Complutensians (*dispositione 4. Phys. q. 1*): "Form is the first act of a body." Others, more commonly and accurately: "Form is the primary act of matter, constituting with it what is one per se." This is drawn from the Doctor (*4. d. 11. q. 3. Y*), and its individual elements are explained. It is called "act" because of matter, which is potency. "Primary" is added to distinguish it from accidental form, which is a secondary act. It is located "of matter" — if it does not presuppose another subordinate form, as the form of an element; but if it does presuppose another form, even in relation to a non-subordinate form, it also holds the role of matter — as the soul, which presupposes the form of corporeity, in relation to which it is an act; hence it is defined as "the act of an organic body" (*2. anima T. 6*). The remaining words are added to distinguish it from the accidental composite, which is one per accidens. The definition of form thus explained is easy to prove by the common and ordinary method — it clearly possesses a genus, which is "act," and a difference, indicated by the subsequent parts; and it contains nothing superfluous and nothing deficient, as a good and fitting definition requires, as Porretan notes in his definition cited above.

Objection I. An absolute being is not defined by a relative one, since each is of a distinct genus. Therefore, since form is an absolute being, it is badly defined through its relation to matter, as is done in the aforesaid definition. Response: I distinguish the antecedent. In the direct case — I concede; in the oblique — I deny. So too an accident is defined by its relation to the substance in which it is grounded, science by its relation to the knowable, and the soul by its relation to the body. Especially because the said definition is not quidditival but descriptive, as Fuentes notes above others (*1. Phys. q. 4. diff. 1. art. 2. n. 7*).

Objection II. What is simple cannot be defined, because a definition consists of parts corresponding to the parts of the defined (*7. Met. T. 33*). But form is simple and a part ordered toward constituting the whole. Therefore no definition of it is to be given. Response: I distinguish the major. By an exact and complete definition — I concede; by an incomplete and rough one — I deny. Especially because form, even if it is simple with the simplicity opposed to physical composition, is nonetheless not simple with the simplicity opposed to metaphysical composition — since it is in the predicament of substance and coalesces from what is quasi-genus and partial difference, being an incomplete and partial substance.

Objection III. A fitting definition does not belong to anything other than the defined. But the aforesaid definition of form belongs to God, who is a first and simple act. Therefore that definition is incongruous. Response: I concede the major; I deny the minor. For God is a pure act composable with nothing, whether physically or metaphysically, and is supremely simple with a simplicity opposed to all composition.

Article III. Whether Form Is Newly Produced in Matter

The Parisians (*Ioannes de Magistris 1. Phys. c. 9. q. 12. art. 3*) and Durandus (*2. d. 18. q. 2*) enumerate three principal classes of ancient philosophers disagreeing among themselves about the origin and production of form, of which two are extremes and the third is in the middle. The first is that of Anaxagoras and his followers, who held that forms proceed from within, are all actually in matter, are contained as if in its bosom — though hidden and confused — and that the natural agent brings them to light, distinguishes and manifests them by its power, like silver immersed in mud, which by the artist's cleansing appears, shines, and gleams. The second is that of Plato in the *Phaedo* and his disciples, who held that forms proceed from without, or from ideas, as universal efficient causes of singular sublunary things, really separated from them. Avicenna adds (*1. suff. cap. 10*) that forms come from a certain intelligence, which he calls the giver of forms. The third consists in a middle position, which belongs to Aristotle and all the Peripatetics, who teach that forms are partly from within and partly from without — that is, forms do not preexist in act in matter before generation, but are contained only in its potency, from which they are drawn by the power of natural agents.

Note I. An agent is divided into equivocal, which is of a different nature than the effect it produces — as the sun is an equivocal cause of the generation of a human (*2. Phys. T. 26*) — and univocal, which shares the same nature and species as the effect it produces. This is further divided into an immediate agent, which immediately attains the effect — as fire immediately generates fire — and a mediate agent, which generates an effect by means of seed severed from itself, as a human generates a human by means of seed.

Note II. From Tatar (*1. de gen. q. 1. Scibili 1*), between creation and generation the following distinction is to be noted. Creation is the production from nothing — that is, from no presupposed subject — so that the terminus from which of creation is nothing, that is the negation of a being. Generation is the production of a thing from preexisting matter, or from a presupposed subject, so that the terminus from which of generation is the privation of the form that is introduced or drawn from the potency of matter. But "to be drawn from the potency of matter" means nothing other than that the form, in its becoming and in its being, depends upon matter, as will be made clear in the next article.

Assertion I. Forms do not proceed from within, as Anaxagoras and his followers hold. This is defended by the Doctors in the commentary on Aristotle (*1. Met. T. 16. sum. 3. cap. 2*) and (*7. eiusdem T. 28*), and has already been proved in article XVIII, question II, of this book. I judge nothing needs to be added for its corroboration, especially since it is an outdated, routed, and obsolete opinion.

Assertion II. Nor do forms proceed entirely from without, as the Platonists hold. This is given by the Doctors (*1. post. q. 3. §. ad quest.*) and rejected by us in Logic

(1. 2. q. 1. art. 3) regarding the ideas that Plato established as the universal efficient causes of singular things — if what Aristotle ascribes to him throughout his writings is true, some of which I cited in the passage referred to. As regards the giver of forms invented by Avicenna, it is condemned as an erroneous opinion by the University of Paris (*cap. 7 of the collection that precedes the first Sentences of the Seraphic Bonaventure*), and Trombetta testifies (12. Met. q. 6). Furthermore, a univocal natural agent generates an effect similar to itself (7. Met. cap. 7, 8) — as fire generates fire and a human generates a human. Therefore the forms of natural things are produced not by an intelligence but by a natural agent. And more to the point, because no intelligence is capable of producing a substance, as Scotus proves (4. d. 1. q. 1. §. *Ista ergo M*) and (§. *Secunda Y*). The principal reason is that an angel acts through intellect and will, which are productive potencies of accidents but not of substance; and what substances are produced by it come to be through the application of active to passive principles, as is clear in the frogs produced by the magicians of Pharaoh (*Exod. 8*).

Assertion III. Material forms are drawn from the potency of matter by the power of natural agents. Scotus teaches this (2. d. 12. q. 1. ante §. *Ad argum. 1. G*) and (4. d. 12. q. 3. I) and (d. 13. q. 1. §. *ex dictis*), and Augustine suggests it (12. *Confess. c. 32, 18*). First proof: what depends in its becoming and in its being upon matter is drawn from its potency, as I observed in note II. But material forms depend in their becoming and in their being upon matter, without which they are neither produced nor conserved, and from which they cannot be separated — otherwise they would be creatable, immortal, and incorruptible, like the rational soul, which is created by God and infused by him into a suitably organized body. Therefore material forms are drawn from the potency of matter by a natural agent. Second: one must philosophize about natural form in the same way as about artificial form (1. *Phys. T. 69*) and (2. *eiusdem T. 36*). But artificial form is drawn from a preexisting matter — as the form of Mercury from stone, and the form of an ox from wood. Therefore the same must be affirmed of natural form.

Objection I. What is in potency is the same as what is in act — as the same man who was creatable is the one now formed (8. Met. T. 15), where Averroes and Scotus agree. Therefore forms are actually in matter just as they are potentially, and consequently they are not drawn from the potency of matter. Confirmation I: something more excellent and noble is not drawn from something more ignoble and inferior; but form is more excellent than matter; therefore form is not drawn from matter. Confirmation II: from Scotus (*Quol. 9*), substantial forms do not depend upon matter, only accidental ones. The reason is, from the same author (1. d. 35): "Nothing that has a more perfect being in any genus depends upon what has a less perfect being in that genus." Response: I explain the testimony of Scotus cited as referring to objective potency, not to subjective potency, of which we are now speaking. To Confirmation I: the major can be

denied. For from earth gold is drawn, from water coral, from a dead grain of wheat a living one, and other things from other things, which plainly surpass in nobility the things from which they are drawn. To Confirmation II: I say that even if this is not explicitly stated in Scotus cited, one must nonetheless answer that substantial forms indeed do not depend upon matter as upon an inherence subject, as accidental forms do — but they depend upon it as upon a sustaining subject, as a part depends upon its counterpart. As to the reason adduced from the same author: I say he explains himself, for he says "in the same genus." Since form, however, depends upon matter not in the genus of formal cause but of material cause, it is consequently not incongruous for the former to depend upon the latter in this way. And this can be explained regarding the whole, which, though more noble than its parts, nonetheless depends upon them essentially.

Objection II. What contains another has that other actually in it, as is clear of a vessel actually containing wine. But matter contains forms, since it is their subject (*1. Phys. T. 82*). Therefore forms are actually, not virtually, in matter. Confirmation: from (*5. Met. T. 2*): "From matter something comes to be as from what is pre-existing in it — as bronze of a statue, and silver of a cup, and their genera." Therefore if matter and form remain, from which the whole coalesces, it is inferred that form preexists actually in matter. Response: the argument concludes about a virtual containment, which is the kind of containment matter has in respect to the form drawable from it by the power of a natural agent. To the confirmation: I say that from preexisting matter as material cause, and from form as another formal cause, the composite is indeed produced; but I deny that form is actually present in matter without being drawn from it by a natural agent, as Scotus indicates in the commentary on the passage cited.

Objection III. The vegetative and sensitive souls are material forms which, according to Scotus (*2. d. 18. q. un.*), have their origin from God. Therefore not all material forms are drawn from the potency of matter. Response: I concede the antecedent; I deny the consequent. The reason is that they indeed originate from God, but not without the intervention and cooperation of matter — therefore they are not created but drawn from the potency of matter by God's power.

Article IV. What It Is for a Form to Be Drawn from the Potency of Matter

Several modes of speaking are recited and refuted on this topic by the inseparable Scotists (*disp. 2. q. 7. art. 2*), Poncius (*disp. 33. q. 2*), and Suarez (*disp. 15. Met. Sect. 2. n. 14*) and following, of which I adduce and express the four principal ones in the next four assertions.

Assertion I. For form to be drawn from the potency of matter is not for it to be drawn from the potency of a natural agent. This is drawn from the Doctor (*2. d.*

18. *q. un. §. contra*) and is contrary to Gerard of Odo, according to the Canonist (2. *Phys. q. 1. dub. 1*). First proof: the eduction from the potency of matter designates a relation of material cause, not of efficient cause, as Fuentes rightly noted (1. *Phys. q. 4. dif. 2. art. 1*). Therefore such an eduction is not from the potency of a natural agent but from the potency of matter as patient. Second: if God were to draw a form from matter, as he draws the vegetative and sensitive souls according to Scotus (*ubi supra, §. Dico igitur I*) — such an eduction would not be from the potency of a natural agent, yet it would be a true and proper eduction. Therefore the eduction from the potency of matter does not consist essentially in the efficient activity of a natural agent. Third: given the opinion of Gerard named above, form would come not from within but entirely from without, as Plato and Avicenna held — both rejected above. For form would be produced by an agent that is extrinsic, while matter does not concur and from which it is extracted, since it is only virtually contained in matter.

Assertion II. The eduction of form from the potency of matter does not require that matter previously exist in time under privation of it, but only in nature. This agrees with Scotus (1. *d. 39. §. quantum ad 1. sub E*) and is explicitly treated (2. *Rep. d. 17. q. 3. §. Item quaro*) against the Coimbricans (1. *Phys. q. 12. art. 5*) and the Complutensians (*ibid. q. 2. §. 3*). First proof: instantaneous productions — such as the illumination of the sun in the air — are true eductions of forms from the potency of matter; indeed all generations of sublunary things, with prior dispositions removed, occur in an instant, as I said (1. *de gen. q. 2. 4. 3*) after Scotus (2. *d. 2. q. 9. sub L*). Therefore the eduction of form from matter does not require priority of duration in matter stripped of form. Second: if God were to draw the form of a worm from new matter in the Eucharist, there would be no duration or succession, since such an eduction would be in an instant and would not be delayed by preceding dispositions — since none would be present there. Therefore it is not necessary that matter deprived of form temporally precede the form to be drawn. Third: accidental forms that by their nature emanate from subjects — as heat from fire and cold from water — are drawn from their potency just as substantial forms from the potency of matter; but subjects do not temporally precede those forms; therefore neither does deprived matter precede those latter forms. For the reasoning is the same in both cases, as Scotus suggests (8. *Met. c. 6. sum. vnic.*).

Assertion III. Nor does the eduction of form from the potency of matter consist in form and the composite being produced by one and the same action. This assertion is at variance with Fuentes (1. *Phys. q. 4. dif. 2. art. 1*) and Suarez as cited (*n. 15*), supported by Lychetus (2. *d. 17. q. un.*) and Mastri (*disp. 2. Phys. q. 7. art. 2*). First proof: from the Doctor (4. *d. 13. q. 1. §. Ad huius autem F*), eduction is a distinct action from generation, because the former is directed to form as its terminus, while the latter is directed to the composite as its total and adequate terminus. But relations are distinguished by their distinct termini, as was decided in Logic (*q. De relatione art. 7*). The same is gathered from the same

Doctor (4. d. 1. q. 1. *ante HH*) and (d. 43. q. 2. §. *potest dici*) and also (2. d. 17. q. 1) and (d. 18. q. un.). Second: the prior is caused as prior before the posterior, as is clear from a cause, which is produced before its effect. But form is prior to the composite, since it is its intrinsic and essential cause; therefore eduction is not the same action by which the composite is produced. Third: form is not generated per se but the composite is (7. Met. Tit. 26) and following. Therefore form is produced by one action and the composite by another. Furthermore, the composite pre-requires the union of matter and form as its constitutive principles, and the simple — namely form — precedes the composite. And if God were to draw form from the potency of matter without uniting it to matter — since they really differ — form would be produced, but not the composite. Therefore form and the composite are produced by distinct actions.

Assertion IV. For form to be drawn from the potency of matter means nothing other than for it to depend upon matter in its becoming and in its being. This is drawn from Scotus in the places cited above, and also in the Reports in the same passages as in the Oxford writings. Canon (2. Phys. q. 1), Bassolis (2. d. 18. q. un. art. 2), and Trombetta (12. Met. q. 5) subscribe to this. First proof: from the refutation of the other modes of speaking in the preceding assertions, of which the present is the better, more fitting, and more common. Second: the eduction of form from matter thus explained is distinguished from creation, according to Scotus (2. Rep. d. 17. q. 3), and from generation and other productions (4. d. 13. q. 1. §. *Ad huius*). Therefore it is to be accepted. Third: the eduction of accidental form from a subject is of this kind (7. Met. T. 16) and frequently elsewhere; and artificial form is drawn in this way from preexisting matter — as from wood or marble — as Antonio Andrea rightly develops (*in exp. lib. sex principiorum, cap. 1*).

Objection II. Against the second assertion: the eduction of form from matter includes in itself an alteration. For it is necessary, in order to draw form from matter, that fitting and suitable dispositions precede, which cannot be produced except successively and in time. Therefore matter with privation of form temporally precedes form to be drawn from it. Confirmation: form is first in potency before it is in act. Therefore prior to the eduction of form from matter the aforesaid temporal priority is required. Response: I distinguish the antecedent. Precisely and formally — I deny; antecedently and extrinsically — I concede. For God can draw form from matter without any temporal interval or gap of duration. I add that generation occurs in an instant, understood as the production of the whole constituted from matter and form; likewise eduction is momentary, understood as the sole production of form in matter. To the confirmation: I say the argument infers only a priority of nature. For it suffices that a cause naturally precede its effect, as is clear from Augustine (6. Trin. cap. 1): "If the sun had existed from eternity, its splendor would have existed from eternity — the sun would have preceded, however, not in time but in nature only," as Scotus rightly develops (2. d. 1. q. 3. §. *Hic dicitur*) and (§. *Tenentes autem M*).

Objection II. Against the third assertion: Aristotle (*7. Met. Tit. 26*) and following writes that form is produced by the same action by which the composite comes to be — that is, it is co-made with the composite. Therefore the eduction of form is the same action by which the composite comes to be. Confirmation: Scotus (*2. d. 17. q. 1. §. Dimissa A*) and (*§. Ad 1. C*) and (*in Rep. ibid.*) establishes that the form drawn from the potency of matter is the form produced by the same production as the whole; while one produced by a different production is created. Response: I say Aristotle there only means that form does not per se come to be or is generated. The Doctor gives the reason in that passage: because if form were generated, and since what is generated comes to be from matter and form, it would follow that form comes to be from form — which is false and absurd. The Philosopher says, however, that form is co-made and co-generated — not because it is not produced by a different action than the action of the whole (since form is prior to the whole and its cause), but because it is not produced by a different action outside matter — and this is what happens with form that is created by the action of the supreme agent. The same response applies to the confirmation. For, as is clear from the passages cited above, form is indeed produced by a different production than that of the composite; yet because it does not pass outside but remains within the limits of matter, it is said to be produced by the same action as the composite, as Lychetus just cited notes.

Objection III. Against the last assertion: the rational soul presupposes matter — namely a suitably organized body. Therefore if our opinion is true, the rational soul is also drawn from the potency of matter — which was rejected above. Therefore our assertion that form's being drawn from the potency of matter is its dependence upon matter in becoming and in being does not seem to be true. Response: I deny the inference. The reason is that in the efficient production of the rational soul, matter does not cooperate as it cooperates in its own genus in the eduction of a corporeal and material form — as the Doctor shows (*2. d. 18. q. un. §. contra primum A*).

Article V. Whether the Forms of the Heavens and the Elements Were Drawn from the Potency of Matter in the First Production of Things

Although the common run of philosophers, with the exception of the rational soul, holds that all forms are drawn from the potency of matter, the moderns nonetheless raise a special question whether the forms of the heavens and the elements in the first framing of the world were evoked from the power of matter by God. Some, cited and followed by the Complutensians (*1. Phys. q. 3. §. 1*) and (*q. 4*) and the Coimbricans (*ibid. in cap. 9. q. 12. art. 5*), deny that both the forms of the heavens and the forms of the elements were drawn from the potency of matter. Others, to whom Suarez adheres (*disp. 15. Met. sect. 2*), though they reject that the forms of heavenly bodies were drawn from the potency of matter, admit this of the forms of elementary bodies. Still others — such as Fuentes (*dif.*

2. q. 4. art. 3), Hurtado (*disp.* 4. sect. 2), and Ruvio (*Tract.* 2. *de forma.* q. 2) — assert that the aforesaid forms were drawn from the potency of matter.

Assertion I. The forms of the heavens were drawn from the potency of matter at the beginning of the world. This is drawn from the Doctor (2. d. 17. q. 1. §. *Dimissa B*). First proof: the said forms depend in their becoming and in their being upon matter, as a true and genuine eduction of form from matter requires, from what was said in the preceding article. Therefore they were drawn from the potency of matter. The antecedent can be further supported. For if the aforesaid forms were independent of matter, they would be incorruptible — like the rational soul — which is false and erroneous. The consequent holds, since matter was naturally created before being adorned with those forms, as the Doctor suggests (2. d. 12. q. 1) following Augustine (12. *Confess.* c. 7, 8). Second: every form is either created or drawn from the potency of matter, as the Doctor teaches (d. 18. q. *unica*, §. *contra*). But the forms of the elements were not created, since they were produced from presupposed matter and depend upon it in being and operation. Therefore they were drawn from the potency of matter. The major is clear because between creation and eduction there is no intermediate. Third: God could in the beginning of the world have created matter together with the fitting dispositions for the form of the heaven; since form and matter are really distinct from one another, he could then from matter so disposed have drawn out the form of the heaven — as among the adversaries Fonseca concedes (5. *Met. cap.* 2. q. 4. sect. 1). Therefore in that case the form would truly have been evoked from the power of matter; therefore also in fact, since no compelling reason to the contrary exists, as is clear from the preceding article.

Assertion II. The forms of the elements likewise, in their first production, were drawn from the potency of matter. This is gathered from the same Doctor (*ubi supra*) and is proved by the same reasons by which the preceding assertion was confirmed and established. But the argument of Suarez cited and of the others is futile and empty, already overturned in the previous article.

Objection I. (*Gen.* 1): "God created the heaven and the earth." Therefore, since by "heaven" are to be understood the celestial bodies, according to Lyra's interpretation, and by "earth" the elementary bodies, it is inferred that their forms were not drawn but created. Confirmation: everything produced is either created or generated; but the heaven is ungenerable and incorruptible (1. *Caeli sum.* 6. *Tit.* 20). Therefore it is created, and consequently its form was not drawn from the potency of matter but created from nothing. Response: the verb "created" is used there broadly, not strictly for producing a thing from nothing, as is clear from that passage of Sacred Scripture: "God created the great sea creatures and every living soul that moves, which the waters produced, according to their kinds." Then: "God created man." And afterward: "God formed man from the clay of the earth" (*Gen.* 2). From these and similar passages it is abundantly clear that creation is taken broadly in the cited Scripture passage as

the production of anything from preexisting matter; but strictly and properly creation is the production from nothing — that is, from no presupposed matter — of which sort is the production of an angel and of the rational soul. By this the confirmation is answered: if the major is admitted by taking "created" in the two senses just explained, the minor is to be distinguished. *Per se* — it is denied; *per accidens* — it is conceded. For the heaven has no contrary, nor is there found in the nature of things a created agent that by its own power could destroy or construct it, as the Doctor rightly notes (4. d. 49. q. 6. §. *Hic duo B*) and (11. Met. sum. 2. in exp. cap. 3), followed by Mauritius in the annotations on the theorems there.

Objection II. The celestial and elementary bodies were produced in a single moment of time together with their parts, so that creation was first directed to those wholes, and then to their parts — which were therefore co-created. Confirmation: the attributes and powers of things are not drawn from them as from a matter or quasi-matter; subsistence is not drawn from the substance of which it is the subsistence; existence and universally the modes of things are not extracted from the potency of those things whose modes they are. Therefore the same must be affirmed of the forms of the heavens and the elements. Response: although those bodies together with their parts were produced in the same instant of time, nevertheless their parts were by nature produced before the composites assembled from them — for parts precede in origin the composites constituted from them, just as principles precede principiated things and causes their effects, and divided things precede the members that divide them, as the Doctor touches on (1. d. 5. q. 1 and 2). To the confirmation: I concede the antecedent; I deny the consequent. The reason is that those attributes emanate, flow, and spring from the natures of things — not so forms. For those attributes do not require an external agent, since they flow from the intrinsic principles of things; but forms do require an extrinsic agent to extract them from the power of matter. The same nearly applies to subsistence, which is the ultimate terminus of a substantial nature; and to existence and the other modes that modify things.

Query: whether eduction is identified with union? Response: No. The reason is that eduction precedes union. For in order for form to be united to matter, it must already have been drawn from the potency of matter. The unifiable extremes are presupposed before they are united, just as I was saying about the parts of a whole. I add that eduction is a relation intrinsically accruing, while union is a relation extrinsically accruing; and the terminus of the former is form, but that is not the terminus of the latter. Furthermore, there can be union without eduction — as is clear with the rational soul, which is indeed united to the body but not drawn from it. These and similar considerations clearly show, against Suarez (*disp. 13. Met. Sect. 9. n. 10*), that eduction is distinct from union.

Article VI. Whether Accidental Forms Are Drawn from the Potency of Matter

I note in the present context that "matter" is not taken here for prime matter but for second matter, which is the whole said to be "matter" because accidental forms are grounded in it. I further note that some accidental forms are real — such as heat — and some intentional — such as light. Real forms are subdivided into natural, which proceed from a natural agent, such as whiteness, and supernatural, which proceed immediately from God, such as grace. Thus, since there are two kinds of agents — natural and supernatural — in proportion to this twofold respect, a form is called natural if produced by a natural agent, or supernatural if produced by a supernatural agent. But in respect to the subject in which it is received, it is natural if the subject inclines to it, violent if the subject resists, and neutral if the subject neither inclines nor resists. This teaching is given by the Doctor (*q. 1. Prol. §. ad q. igitur L*). Furthermore, some forms are artificial, worked by an artisan through art, such as the form of a house.

Assertion I. A natural, real accidental form is drawn from the potency of a subject. This is common, defended particularly by Scotus (*4. d. 1. q. 1. §. Idea dici potest GG*) and Mayr (*2. d. 13. q. 4*). First proof: every such form depends in its becoming and in its being upon the subject of which it is an accident, as a genuine eduction of form from the potency of matter requires. Therefore it is drawn from the potency of its subject. The antecedent is at hand: since an accident's being is to be in a subject — that is, to inhere in a subject — from which it either naturally proceeds or is produced by another and grounded in that subject or in another. Second: such a form is not created. For since it is produced by a created agent, it cannot come to be through creation, since a created agent can neither principally nor instrumentally attain creation, as Scotus teaches in the passages just cited. Nor is it generated — since generation belongs to the composite alone (*7. Met. Tit. 27*). Therefore it is drawn. Third: what proceeds from matter or from the composite is drawn, since eduction is the dependence of form upon matter or another subject in becoming and in being. But every accidental form proceeds from the matter in which it inheres, according to some; or from the composite, according to Scotus and other philosophers. But matter or the composite cannot cooperate in creating anything, since creation belongs to the supreme independent agent. Therefore every natural form just mentioned is drawn from the power of matter.

Assertion II. A natural intentional form is drawn from the potency of a subject. The Doctor presupposes this (*2. d. 13. q. unic.*), and Mayr (*ubi supra*) and Richard (*eadem d. art. 2. q. 1*) explicitly defend it, followed by the greater part of the moderns. First proof: an intentional form is natural, just as a real form is. For it produces a real natural effect — as light illuminates a medium, a sensible species cooperates partially in sensation, and an intelligible species cooperates in an act of understanding. But a natural real form is drawn from the potency of its

subject, as proved in the first assertion. Therefore so also is an intentional form. Second: what is produced with the cooperation of a subject is drawn from its potency, as the word "eduction" indicates. But light is produced with the sun's cooperation, and an intentional species is co-caused by the object whose role it plays. Therefore every intentional form is extracted from the power of its subject. Hugo of St. Victor adds (*lib. de sacr. part. 6. cap. 26*): "Works of creation, multiplication, and annihilation are possible for God alone." Therefore since light proceeds from a luminous body and intentional species from objects, it is clearly inferred that such forms are drawn from the potency of the subject.

Assertion III. Supernatural acts — such as the acts of faith, hope, and charity elicited by a created agent — are drawn from the potency of their subject. The Doctor teaches this (*1. d. 17. q. 2. §. Ad argumenta pro opinione PP*). First proof: the aforesaid acts are elicited by a created agent dependently upon the subject, just as natural acts are caused partially by a habit and an eliciting potency. But these are drawn from the potency of their subject; therefore those are too. Second: only an act immediately produced by God is properly said to be created, because it belongs to God alone to act independently of matter and subject. But such acts are caused by a supernatural habit and a natural potency — namely the intellect or will. Therefore they are not properly created but drawn from the potency of the subject.

Assertion IV. Supernatural habits — such as faith, hope, grace, and the light of glory — are created by God. The Doctor holds this (*1. d. 17. q. 2. §. Ad solutionem*) and (*§. sexto q. 3*) and (*2. d. 34. §. Ista quaestiones A*) and (*4. d. 1. q. 5. §. Ad primam ergo*). First proof: what is produced immediately by God alone is created, since creation is the production from no presupposed subject, and God alone acts independently of matter and subject. But the aforesaid habits proceed from God alone — as of grace and the light of glory specifically is found in (*Ps. 83*): "Grace and glory you will give, O Lord." Therefore they are created. Second: the aforesaid habits are not drawn from the potency of their subjects; therefore they are created. The consequence holds because there is no other mode of producing them. The antecedent is proved: forms that are drawn from the potency of a subject are natural; but those habits are supernatural and so eminent in their order as the rational soul is in its own catalogue — and the rational soul is created; therefore so also are they.

Assertion V. Artificial forms are drawn from the potency of the subjects from which they are extracted and in which they are grounded. This is drawn from Aristotle (*1. Phys. T. 69*) and (*7. Met. sum. 2. cap. 7. Tit. 27*) and Scotus there, who compare natural forms with artificial ones. But the former, as established above, are drawn from the potency of matter; therefore so also are the latter. Furthermore, art can accomplish nothing except from preexisting matter, as is confirmed by experience — the carpenter, to make a seat, presupposes wood; the blacksmith, iron; and so with the rest. Further, art presupposes nature, of

which it is an imitator (2. *Phys. T.* 79). But nature does not produce form from nothing, since from nothing nothing comes to be naturally; therefore neither does art — and consequently artificial forms are drawn from the potency of a subject, just as natural forms are.

Objection I. Against the second assertion: the eduction of form from matter is a real action having a real terminus and proceeding from a real physical agent. But light is an intentional form, as the Doctor concedes (2. *d.* 13. *q.* *vn.*).

Therefore an intentional form is not drawn from the potency of a subject.

Response: with Scotus just cited, light participates in both. It is a real form, because it really illuminates the medium; and it is an intentional form, because through that illuminated medium an object bathed in light is seen by us.

Objection II. Against the fourth assertion: an accident's being is to be in a subject, from Aristotle (7. *Met. cap.* 1. *T.* 2) and Scotus (4. *d.* 12. *q.* 5. §. *Ad q. respondeo sub E*). But supernatural habits are accidents; therefore they are in a subject, depend upon it in being and becoming, and consequently are not created. Confirmation I: creation is of self-subsisting things; but the said habits do not subsist, since they are not substances; therefore they are not created. Confirmation II: what God creates persists in eternity — as the rational soul and the angel; but the aforesaid habits do not always endure — as faith and hope do not remain in the fatherland; grace perishes through sin. Therefore such habits are not created. Response: aptitudinal inherence in a subject is indeed a property of an accident. But this does not prevent the said habits, which are accidents, from being created by God. For the rational soul is in the body, informs it, and yet is created; likewise the said habits are in the subject which they inform, and yet are created by God. To Confirmation I: I deny the major, which is supported by no argument. Therefore it is dismissed with the same ease with which it was advanced. To Confirmation II: I say the major is not universally true — even if true of the rational soul and of the angel, it is not true of grace, which on account of the demerit of the sinner is annihilated by God, as the Doctor writes (2. *d.* 35. §. *Ex ista solutione Ad 2. in fine*) and (3. *d.* 23. *q.* *vn.* §. *Ad 1. principale sub K*).

Objection III. Against the fifth assertion: what is drawn from the potency of a subject is drawn by a proper and distinct action of the agent, as the verb "to be drawn" indicates. But artificial forms result from cutting, planing, and polishing, which are local motions by which the instruments of artisans are moved and the parts of the matter from which the artificial whole — such as a statue or a house — is constituted are brought together. Therefore the said forms are not drawn from the potency of a subject. Response: I concede the major; I deny the minor. For even if those aforesaid motions are pre-required, nevertheless the aforesaid forms are produced by a proper action of the artisan — since art is a habit productive together with right reason — and are drawn from the power of the subject, just as other forms, as Antonio Andrea states (*in exp.* 1. *sex principiorum*).

Article VII. Whether Several Substantial Forms Can Simultaneously Inform One and the Same Matter in Number

The present dispute is not about subordinate substantial forms, of which one is presupposed and ordered to another — as the form of corporeity and the form of the living being, treated (*in 2. de anima*) — but about disparate and unrelated forms, of which the one does not regard the other, such as the form of a dog and of a lion. The proposed and put forward difficulty can be treated in two ways: naturally and supernaturally. With regard to the first way, hardly anyone asserts that several forms can simultaneously inform one and the same matter — both because one form sufficiently and totally completes and perfects the matter it actually informs, and because from those forms there would arise what is one per accidens, since one would accrue to another when the whole was already constituted, which is an accident. Moreover, one form does not coexist simultaneously with another, as experience confirms: "The generation of one thing is the corruption of another," as one reads in Aristotle (*1. de gen. cap. 3. T. 17*) and Scotus (*2. d. 1. q. 5. §. Ad 1. arg. L*). For the agent must necessarily, in order to generate a new composite, expel the original form so as to introduce a fresh form into the same matter — since both simultaneously in the same subject are incompatible, as Scotus writes (*2. d. 2. q. 7. §. Ideo ante D*) and (*5. Met. q. 7. §. pro solutione*) and (*2. d. 15. q. vn. §. Dico ergo sub A*) and (*d. 1. q. 3. sub L*). With regard to the second way, however, there is no small controversy among the scholastics. For Gregory (*2. d. 12. q. 3. art. 2*), Fonseca (*5. Met. c. 4. sect. 5. q. 4*), Ruvio (*tract. 2. de forma q. 7*), to whom the twin Scotists (*disp. 5. q. 7. art. 2*) and Poncius (*disp. 33. q. 33. q. 3. concl. 2*) adhere, following Sghemma (*2. Phys. digreff. 7*), affirm this. But Fuentes (*1. Phys. q. 4. dif. 3. art. 1*), the Complutensians (*ibid. disp. 4. q. 6. §. 1*), Vasquez (*de incar. disp. 24*), Arretinus (*in annot. q. 19. primi Phys.*), and several others of both schools deny it.

Assertion. It cannot be brought about by uncreated power that two substantial forms simultaneously inform one and the same matter in number. The Doctor holds this in explicit terms (*4. d. 49. q. 16. §. Ad 1. argum. prop. finem*): "Nor can it be said that it is in alien matter, because two specific substantial forms cannot simultaneously perfect the same matter." He suggests the same (*ibid. 4. d. 11. q. 3. §. Alij concedentes*) and (*d. 10. q. 2. §. Dico ergo*) and (*2. d. 2. q. 7. §. Et ideo D*) and (*Quol. 9. §. De secundo*). Lychetus and Gadius agree in those places. Someone might say either that Scotus is proposing and opposing arguments against the assertion he himself holds — as in the first passage cited — or that he is speaking naturally. Therefore Scotus is not a proponent of the aforesaid assertion. On the contrary: Scotus himself, in the former passage, answers those things that fight against his teaching and refutes the contrary. But to the incompatibility of two forms simultaneously in the same matter, he gives no answer — and this is evidence that he in no way admits it, as becomes clear afterward in the other passages just mentioned, in which he reasons about created power. As is clear to anyone reading the adduced testimonies, Poncius therefore wrongly draws

Scotus himself into the opposite opinion — as is also made clear by the reasons to be adduced presently, which are in conformity with his principles to support our proposed assertion.

The assertion is proved, first: what is per se, simply, and ultimately subsisting through one substantial form and one matter, cannot tolerate another substantial form in the same matter in number, because that is a supposit or person which is incommunicable both as "by which" and as "which," as the Doctor explains (*Quol. cit.*). But a composite of matter and one substantial form is simply subsisting, since it is a supposit. Therefore in that matter there can exist only that one form that informs such matter — and consequently two substantial forms cannot coexist simultaneously in the same matter. This argument is akin to that first one which the Doctor gives in the passage cited above, to prove that an angel cannot inform matter.

Someone might say the argument does not conclude, since a supposit is adequately subsisting, independent, and incommunicable, while a composite of matter and form is not subsisting except through the suppositional being which is its ultimate terminus. Therefore nothing prevents matter, which does not subsist by the subsistence of a form but of the whole, from being able to receive two forms simultaneously in itself. On the contrary: suppositional being is the terminus of both natures assembled from them. Therefore if one form in its own genus and order totally and simply causes it, another cannot simultaneously cause that same being — otherwise the same effect would simultaneously be caused by two causes of the same order and kind, which Scotus denies (*3. cit.*).

Someone might say this holds for total and adequate causes, but not for partial and inadequate ones. On the contrary: just as two total causes cannot totally and simultaneously produce the same individual effect, so neither can two partial causes of the same order and kind simultaneously and partially, though inadequately, attain the same individual effect. For in their own way, the reasoning runs equally in both cases. Second: if two substantial forms were to simultaneously inform the same matter in number, they would give it either an act simply or an act in a qualified sense. Not the latter, since that belongs to an accidental form that accrues to a thing already complete and perfect in its essential and substantial being. Nor the former, since it is the common maxim of the philosophers that from a twofold act simply there arises what is one per accidens. Therefore in no way can two substantial forms coexist simultaneously in the same matter. This argument is similar to the latter one which the Doctor uses in the cited *Quodlibet* to show that an angel cannot be united to matter as an informing form.

Someone might say, with the cited Poncius, that this holds naturally but not supernaturally. On the contrary: what is required for the essence of something cannot be supernaturally removed without its essence being destroyed. For it

cannot be that there is a human unless he consists of body and soul, nor a binary unless it is assembled from two. But from act and potency — that is, from matter and form — what is one per se arises (8. *Met. T. 15*), and no other reason is given except that the one is potency and the other is act; and from a twofold disparate act there arises what is one per accidens — and no other reason is adduced except that each is an act, and neither is ordered to the other, but one is accidental to the other. Therefore it is impossible for two forms to simultaneously inform a single matter — otherwise one would be ordered to the other, and they would be subordinate, which is contrary to the thesis. Furthermore, is matter completely and fully actuated by one form, or is it not? If not, then the whole assembled from both is not complete — which is false. If it is, then while that form remains in matter, there is no aptitude or capacity in it to simultaneously receive another form — just as while whiteness remains in a wall, there is no capacity in it to simultaneously receive blackness.

Third: if one matter in number could simultaneously be informed by two forms, it could also be informed by three — indeed by infinitely many, if there were infinitely many — since no stronger reason appears for two than for infinitely many. But this is impossible; therefore so also is the former. The major is shown from the Doctor (3. *d. 1. q. 2. §. Contra*), who employs the same form of argument against Varron: "If human nature could be supposed by several supposits, then by infinitely many, since no determination to a fixed number is apparent." Analogously, if one matter could be actuated simultaneously by two forms, then also by infinitely many — and so it would be infinite, since it would be the receptacle of infinitely many forms. Nor does it help to say with the cited Poncius that this does not argue such an infinity in matter as is not argued by the infinity of a place, which can receive infinitely many bodies. For, beyond the fact that the Doctor argues in this way in the passage cited, a place receiving several bodies does not have this from within — as matter would have on the given hypothesis — but from without, as Lychetus rightly explains there from Scotus (4. *d. 10. q. 2. §. Dico ergo K*).

Fourth: it is repugnant for a human nature, and for any other singular and numerical substantial nature, to be supposed simultaneously by three supposits. Therefore it is also impossible for the same matter in number to be actuated and informed simultaneously by several forms. The antecedent is Scotus's in the third passage just cited. For it is impossible for the same nature to depend adequately and totally on many supposits simultaneously — just as it is impossible for one effect to be caused simultaneously by many total causes of the same genus and order, otherwise it would be caused simultaneously by them and would not be caused, and would simultaneously depend essentially upon them and would not depend, as the Doctor excellently infers in the passage cited. The consequent is proved: one form is the total informative and completive principle of one matter, and the total determinative principle of the same in a fixed species and individual. Therefore the very same matter cannot

simultaneously be adequately and totally actuated, informed, and determined by another form — otherwise it would be totally actuated and informed and would not be totally actuated and informed by that form, since it is totally actuated and informed by another.

Someone might say that form does not fully and adequately complete the appetite of matter nor adequately perfect it. Therefore the adduced parity with the plurality of supposits and forms does not hold. The antecedent is the common saying of the philosophers, notably Scotus (2. d. 1. q. sec. *ad finem*) and (2. d. 14. q. 1. §. *Respondeo B*). On the contrary: even though matter, in respect to another form, inclines to it and desires it, it does not do so with the same appetite simultaneously but separately, with a distinct appetite. Hence the Doctor in the first citation premits that there are as many appetites in matter as there are forms receivable in it. Therefore the parity holds, and the argument retains its force — whatever our aforesaid modern authors may contrive to assert to the contrary.

Objection I. Matter is the receptive subject of all forms, no more determined to one than to another, since each is its perfection and complement. Therefore one matter in number can be informed by two forms for which it is disposed and prepared. Response: I distinguish the antecedent. Successively — I concede; simultaneously — I deny. Just as wood is suited for the artisan to draw from it the form of Jupiter or Mercury, yet those images can be formed in that wood not simultaneously but successively. Analogously, Scotus in the third passage cited concedes that one nature, taken separately, can indeed be hypostatically and personally assumed by three persons, but not jointly.

Objection II. By the absolute power of God, two bodies can simultaneously exist in the same place, according to Scotus (4. d. 49. q. 16); several relations can exist in the same foundation (3. d. 8. q. un.); and very many accidents can exist in the same subject (5. Met. q. 7). Therefore also two substantial forms in the same matter. Response: I concede the antecedent; I deny the consequent. The reason for the disparity is that all those things are extrinsic to the subjects in which they reside, and they accrue to them complete and perfect in their own being — therefore they are forms in a qualified sense. But a substantial form intrinsically constitutes and essentially actuates matter, and determines it in a fixed species and individual; therefore it is a form simply — and consequently, while one remains in the same matter, another cannot simultaneously coexist in that very matter, because of their incompatibility and repugnance.

Objection III. By the supreme power of God, two contraries in the highest degree can simultaneously exist in the same subject — as supreme heat and supreme cold; therefore likewise two forms can simultaneously inform the same matter in number. Response: I deny the antecedent with Scotus (1. d. 17. q. 3. §. *Contra istam opinionem*) and (3. d. 4. q. un. §. *Ad argumenta H*), after Aristotle (4. Met. Tit. 19 and 27). For if contraries in the highest degree could simultaneously

inform the same subject, contradictories would simultaneously be true of the same thing. Therefore if contradictories cannot be simultaneously verified of the same subject, neither can contraries simultaneously inhere in the same subject.

Article VIII. Whether One Form Can Simultaneously Inform Several Matters

The views of the philosophers here are nearly as many as those set out in the preceding article. Indeed, naturally no one doubts that no form can simultaneously inform many matters. But that it is possible supernaturally is asserted by Fonseca (5. *Met. cap. quarto, sect. tertia, q. quarta*), Ruvio (*Tract. secundo de forma, q. septima*), as indicated by Auriol (3. *d. 1. q. quarta, art. secundo*) and Durandus (*ibid. q. tertia*), followed by Poncius (*disp. trigesima tertia, q. quarta*). That it is impossible, however, is indicated by Scotus (3. *d. 1. q. 2. §. Ad quest. A*), Lychetus there, Faber (*disp. quarta*), Fuentes (1. *Phys. q. 4. dif. 3. art. 3*), and Mastri (*disp. quinta, q. septima, art. secundo*). And Richard had previously indicated this (3. *d. 1. q. 4*).

Note I. Form is divided into partial or inadequate — such as the form of a head or foot — and total or adequate — such as the form of the whole body. Again, into conjoined, which is integrated from all the parts simultaneously, as a form that simultaneously informs all the parts of the body joined together; and into disjunct, as if form were to inform certain parts severed from the whole and remote in place. Further, into divisible or material, which is drawn from the potency of matter, such as the soul of a dog; and into indivisible, which is created by God, such as the rational soul. The question is principally whether one complete and total form can inform several total and adequate matters in number; and also whether it can simultaneously inform several partial matters, severed and remote in place.

Note II. The more extensive and unlimited a form is in informing and perfecting many things, the more excellent and perfect it is — as is clear from the rational soul, which primarily and adequately perfects the whole body, and inadequately its individual parts, since it is whole in the whole and whole in all its parts. But since form confers essential and perfectional being upon the body it informs, if it could adequately inform several bodies simultaneously, it would be more perfect; and if infinitely many simultaneously, it would be infinite — because it would confer perfectional being upon infinitely many, which it could not do unless it were infinite. As Lychetus rightly inferred from Scotus cited about a nature giving being to infinitely many supposits.

Assertion I. One form by the force of nature cannot simultaneously perfect two adequate matters, nor two inadequate matters remote in place. The conclusion is twofold, as the Doctor suggests (8. *Met. in com. cap. 6. Tit. 15*) from Aristotle there, and (2. *d. 1. q. 3. §. Ad 1. L*) and (*d. 12. q. 1. §. positio*) and frequently

elsewhere. The first part is proved, first: adequate perfection by its very nature requires an adequate perfectible. For one thing is seen by experience to be adapted and proportioned to another. But form is the adequate perfection of matter, and matter is its adequate perfectible, since from both joined together what is one *per se* arises, as the Philosopher says in the passage just cited — for no other reason than that matter is potency and form is act. But if another form of the same order is added, what is one *per accidens* arises — for from a twofold act what is one *per accidens* arises (7. *Met. T.* 26). Therefore one form requires one matter only. Second: only two intrinsic causes are required to constitute a composite, which is distinguished from what is simple in that it consists of two parts — namely matter and form — while the latter is devoid of parts, as the Doctor develops well toward the end (§. *positio ista. d. 12. secundi q. 1*). Third: a metaphysical composite coalesces only from genus and difference, and an individual from nature and individual difference — as a human from animal and rational, and this human from humanity and thisness — as Scotus teaches (2. *d. 3. q. 6. §. Ad q.*). Therefore a physical composite is certainly also content with one form and matter. It is further clear in the perpetual motion and vicissitude of sublunary things, as well as in their birth and perishing — whether of elements or mixed things — that only one matter and one form are found: as when air becomes water and water becomes air. In these and other cases, the same matter is in the generated thing as was in the corrupted, as the Doctor notes (5. *Met. in exp. capitis sexti Titulo duodecimo*). Finally, an agent, in order to introduce a recent form into matter, must necessarily expel the original form. From which that common saying derives (1. *de gen. Titulo vigesimo*): "The generation of one thing is the corruption of another." Therefore one form encompasses only one matter. The second part is evident: if a hand is amputated from a human, that hand dies; and if a branch is cut from a tree, that branch perishes. The reason is that the soul informs the organic body, its members, and its continuous and contiguous parts joined and linked together; therefore if such parts are severed and separated from it, the soul ceases to inform them and to give them life — and so they pass away and perish.

Assertion II. It is impossible for one form to adequately perfect several total matters. The Doctor holds this in the third passage cited (§. *contra hoc obiicitur*). First proof: what is of the intrinsic and formal notion of something cannot, even divinely, be otherwise — as it is of the essence of a human to be a rational animal, so it cannot be that there is a human who does not participate in the nature of a rational animal; so that it is necessary that he consist of precisely these two — animality and rationality — neither more nor fewer. But a physical whole is composed of matter and form, and is a third thing essentially assembled from both (7. *Met. Tit. 7. cap. 1. sum. secunda*). For its essential definition is thus: and what enters into the definition of a thing is of its essence — especially since matter and form are causes, parts, and constitutive principles of the whole (2. *Phys. T.* 52) and (5. *Met. T.* 2). Therefore it involves repugnance for

one form to totally inform many adequate matters. Second: matter and form are relatively opposed (*2. Phys. Titulo vigesimosexto*), and form is the terminus of generation, from which the relation is specified. And in as many ways as one of the opposites is said, so also the other (*1. Top. cap. duodecimo*). But in the preceding article I showed that one matter, by either created or uncreated power, cannot be informed by several forms; therefore neither can one form simultaneously inform several matters. Third: those things are numerically one whose matter is one (*5. Met. cap. sexto, Titulo duodecimo*) — which Scotus there explains as referring to the individual difference by which a nature is singularized and individuated. Therefore if one individual difference is required for singular being and suppositional being, one suppositional being follows — so that several suppositional beings and singularities in one and the same simultaneously repugn. The same must be affirmed of several matters in relation to one form. What I adduced in the preceding article to corroborate that assertion also pertains here.

Objection I. Certain saints — such as Denis at Paris and Mitre at Aix — carried their amputated heads in their own hands for some miles and at that time preached to the people; which could not have occurred unless the soul informed the head severed from the body. Therefore it does not involve contradiction for a form to simultaneously inform and perfect several matters remote from one another in place. Response: this was accomplished through a miracle — not in order that one and the same soul should inform several total and adequate bodies, but only certain members, which are parts of the body and inadequate matters, such as the head of which mention is made in the argument.

Objection II. Place is an accidental form and can be simultaneously in two subjects informing them — as if two bodies were to exist simultaneously in the same place. Scotus holds it possible by divine power (*4. d. 49. q. 16. §. Respondeo F*). Therefore if one accidental form can simultaneously inhere in two adequate subjects and inform them, certainly one substantial form can simultaneously perfect two total matters. The parity is conceded by the Doctor (*3. cit.*). The Doctor responds (*§. Ad argumenta D*): there is one material place and a twofold formal one — for on the given hypothesis the two bodies would be encompassed by the same surface, which is the material place; but there would be two active circumscriptions and localizations of the two said bodies, which are the formal places, as Gilbertus notes (*lib. 16. Sex principiorum, cap. 5*). Someone might say: the same surface encompasses those two aforesaid bodies, and since it is an accident in them, it undoubtedly inheres in them. But a surface is an accidental form of the genus of quantity. Therefore one form can simultaneously inform several total and adequate subjects. Response: I say the surface only encompasses the body that is circumscriptively in place — but not another, which prescribes from local replenishment, as the Doctor establishes (*4.*

passus memorato). And so it does not follow that one accident simultaneously inheres in two adequate subjects.

Objection III. One supposital being or personhood can terminate the dependence of two supposable or personalizable natures, according to Scotus (3. d. 1. q. 3). Therefore also one form can simultaneously perfect two adequate matters. Response: I concede the antecedent; I deny the consequent. The reason for the disparity is that form is a real positive being, really informing the matter of which it is the form; while supposital being formally presents only a twofold negation — as "by which" and as "which." And if it is defended that personhood formally designates something real and positive — as the Doctor holds as probable — one may say it stands as a cause in respect to the supposable and personalizable nature. But it is not repugnant for one cause to simultaneously have several effects, as is clear from a father who simultaneously has several children. I add that Scotus in this and several other matters is problematic and shows that the opposite opinion does not lack probability — which Bassolis, Mayr, Poncius, and many others defend. But he seems to incline to the negative side, as Fuentes noted above (*art. 3*), and his principles and foundations indicate this. Someone might say Scotus in the passage cited frankly acknowledges that the divine supposit can supposit several natures simultaneously, and that in fact in the unity of the divine supposit of the Word the divine and human natures are united. Therefore there is absolutely no implication at all. Response: there is a disparity, since a created supposit enjoys only a twofold incommunicability, while a divine supposit has a threefold one — on which I treated at length in the treatise on the Incarnation.

Question V. On the Union of Matter and Form

Union requires the extremes it unites and simultaneously connects, so that from them there arises one thing, which is a third constituted from them. Therefore, having examined matter and form — which are the two extremes to be joined together in order to cause the composite — it is now fitting to dispute about the union of both.

Article I. Whether There Is a Union Distinct from Matter and Form

The prior opinion belongs to Ockham (1. d. 30. q. 1), Gregory (*ibid.* d. 26. q. 2), Auriol (2. d. 22. q. 1. art. 3), and the other Nominalists and many Thomists, who affirm that matter and form are united by themselves, so that no bond is interposed between them distinct from them. The posterior position is that of Scotus (2. d. 1. q. 5. §. *contra istam opinionem ante A*) and (3. d. 2. q. 2) and other places, and of his disciples and not a few Thomists, who teach that the union of matter and form is something distinct from them.

Note. Union is taken in three ways. First, for an aggregation or conjunction of certain things — so many stones are joined for the construction of a house, and

many soldiers for the composition of an army. Second, for the concord and love of many — so in (*Ioan. 17*) Christ the Lord prays to the Father that his disciples may be one — namely, in love and charity. And Augustine, cited by Calepinus, adds: "For who doubts that this can occur in so great a union of souls?" Third, for the bond or link of matter and form for composing the whole — and it is about union taken in this sense that the philosophers dispute here.

Assertion I. Matter and form are not united by themselves to make the composite, but by means of a union distinct from them. The Doctor holds this in the passages just reviewed. First proof: union is the bond of two extremes distinct from one another. For nothing is united to itself but to another — since from Scotus (*4. d. 43. q. 3. §. Hic duo sub B*), union is the relation of one being to another — that is, of the perfectible to the perfecting, and of the perfecting to the perfectible — or the respect of matter to form and conversely, as will be more apparent in the next article. But a relation or respect differs from the extremes of which it is the respect, since those extremes are absolute, while the relation is a relative being, and it is the common dogma of the philosophers that a relative being differs from an absolute one. Therefore union differs from matter and form. Second: unless union adds something real and positive above the united extremes, the separated extremes would be united, and things united simultaneously would be separated — which is self-contradictory. Therefore union is distinct from the united extremes. The consequent of the antecedent is shown: if union does not differ from the extremes, since the extremes retain exactly the same essence and existence whether separated from one another or joined, it is rightly concluded that separated things are joined and vice versa — which involves repugnance. Someone might say: when they are united, one is in the other — namely form in matter — and both enjoy mutual presence. On the contrary: at least by divine power, form can be in matter and present to it without any information or causality, as is clear with an angel and with God, who are present to things without informing them. And more to the point, because approximation and presence — according to the Nominalists against whom we are arguing — present no real positive being; therefore the argument retains its force and strength. I add that approximation, presence, and the like are rather prerequisite conditions than essential to the said principles. Third: a thing is not changed unless it newly receives something real in itself, as the Doctor notes (*2. d. 1. q. 5. §. Secundum primam T*). But when matter and form are simultaneously united, they are changed — for matter goes from not being informed to being actually informed, and form from not informing to actually informing. For it is impossible to pass from one contradictory to another without change, as the Doctor argues (*1. d. 39. §. Ad tertiam quaestionem*). Therefore union implies something distinct from the simultaneously joined extremes. Fourth: the divine Word and humanity are simultaneously united in the hypostatic union, which differs from them both joined together — as is clear in the triduum in which it was removed when Christ truly died. Likewise in logic

the union of subject and predicate differs from them; and this is easily induced from the remaining unions of other things.

Assertion II. Union is really distinct from matter and form simultaneously united. This is drawn from Scotus in the passages cited. First proof: those of which one remains while the other perishes are beyond doubt really distinct from one another — as Peter and Paul are really distinguished from one another, since Peter lives while Paul is dead. But when union is dissolved, the extremes can remain — as is clear at the death of Christ the Lord, in which the union of humanity with the Word was destroyed while the Word itself and his rational soul persisted. Second: what can exist separately, at least by divine power, really differs. But matter and form by divine power can exist separately with their union destroyed, as is clear at the death of a human, in which the union of soul and body perishes while both persist. Therefore between the united extremes and their union there intervenes a real distinction. Someone might say: union cannot exist without the united extremes, just as a relation cannot be without a foundation and a terminus. Therefore if it is impossible for union to be separated from its extremes, it clearly follows that it does not really differ from them. On the contrary: a predicamental relation, from what was said in logic, really differs from its extremes, and yet is inseparable from them. Likewise the composite is really distinguished from its parts simultaneously united, and yet cannot be disjoined from them because of the essential dependence it has upon them. So the same must be said of union, which — being a relation — has an actual dependence upon the extremes it connects; therefore it cannot be separated from them, even though between them and it there falls a real distinction.

Objection I. Against the first assertion: matter and form are immediately united to one another by the agent so as to cause the whole. Therefore no union intervenes between the two. The antecedent is shown from (8. *Met. Tit. 15*) and (2. *de anima, Tit. secundo*): "From matter, which is potency, and form, which is act, what is one per se comes to be, and nothing further is required as a medium for connecting those two extremes." Response: I distinguish the antecedent. Matter and form are immediately united as "what" — I concede; as "by which" — I deny. As to its proof, this is clear by the same distinction: for union is not united but is that by which matter and form are united — just as action is not acted but is that by which an agent acts; and place is not located but is that by which a body is located. Hence from matter and form as immediate and essential parts what is one per se arises, and these the agent connects by means of union as their bond.

Objection II. If there were a union to simultaneously bind matter and form, it would either precede form in matter, accompany it, or follow it. Not the first, because since union is a relation, it presupposes the extremes, one of which is form. Not the second, because matter more immediately and directly regards form than union, since the former is a substance and the latter an accident; and

the substantial order precedes the accidental order, as I shall show (*1. 5. q. 1*). Not the third, because nothing posterior necessarily connects what is prior and really distinct from it. Therefore no union of matter and form distinct from them is to be admitted. Response: union follows matter and form, from which as its extremes it arises. Nor is it incongruous that a posterior thing necessarily follows — just as existence follows essence, subsistence substance, relation its extremes, and a creature follows God.

Objection III. If there were a union differing from matter and form, it would be either a substance or an accident — neither can be said; therefore it is not to be conceded. The major is clear because substance and accident immediately divide being. The minor: it is not a substance, because substance is sufficiently divided into matter, form, and composite (*2. Anima Tit. secundo*); nor is it an accident, otherwise the union would be accidental, and consequently the whole would be a being per accidens, which conflicts with (*8. Met. Tit. decimo quinto*) where the Philosopher establishes that from matter and form simultaneously joined there arises what is one per se. Response: I concede the major; I concede the first part of the minor; but I deny the second part and its inference. For even though union is formally an accident, it is nonetheless substantial — because its extremes are substances, just as generation is called substantial not formally, since it is an action, but terminatively, because its terminus is a substance. Likewise the hypostatic union of the divine Word is called substantial by Scotus (*3. d. 7. q. 1. art. quinto*), because its extremes are substances and united in the subsistence of the Word himself — even though it is formally an accident, namely a relation extrinsically accruing, from the same (*ibid. d. 1. q. 1. art. 1. A. §. de primo dico*).

Article II. What the Union of Matter and Form Is

Several moderns — such as Suarez (*3. p. disp. 8*) and Vasquez (*ibid. disp. decimasecunda, cap. tertio*) — hold that the aforesaid union is a substantial mode, which is the foundation of a transcendental or predicamental relation, as others think. But Scotus, in both the places cited in the preceding article and also (*3. d. 22. q. vn. §. Ad 1. arg. L*) and (*4. d. 12. q. 1. §. Ad q. N*) and (*d. 43. q. 1. ante §. Aliter ponitur sub B*), Bassolis (*2. d. 12. q. 2*) and (*3. d. 1. q. 1*), Oviedo (*ibid. dub. 2*), and Mastri and Bellutus (*disp. 5. Phys. q. 9*) teach that this union is a predicamental relation extrinsically accruing.

Note. Union is taken in two ways. First, actively — so union is the same as the unitive action of a natural agent uniting matter with form. For it is necessary that matter and form be united before the composite is generated, as Scotus agrees (*1. Rep. d. 1*): causes always precede their effect, at least by nature. Second, passively — in which way union is the effect of the uniting action of the agent that unites matter with form; and this union is the bond or link of both. This teaching is excellently explained and corroborated by Faber (*3. disp. 3. cap. 3*) regarding the hypostatic union of the divine Word with human nature, in which

through the action of the most holy Trinity nothing is produced except a relation extrinsically accruing to the dependent and sustained nature, in relation to the independent Word, sustaining personally and hypostatically — as the Doctor excellently notes (*in Rep. 3. d. 1. q. 2*).

Assertion I. Union is not a substantial mode. Defended by the Doctor (*3. d. 1. q. 1. §. De prima A*) and (*in Rep. q. 2*). First proof: a substantial mode is intrinsic to the thing of which it is a mode, since it follows its nature and is inseparable from it, and is distinguished ex natura rei or modally from it — as the adversaries seem to concede. But the union of matter and form can be destroyed while they persist — as when the composite is corrupted, the union perishes while matter and form remain, separated from one another in the death of a human; and by divine power they can persist separated, since they really differ, as the Doctor signifies (*2. d. 12. in fine q. 2*). Therefore union is not a substantial mode. Second: every being is either a substance or an accident (*5. Met. T. 14*). But that mode is not an accident, as the adversaries concede; nor is it a substance, which (*2. anima T. 2*) is sufficiently divided into matter, form, and composite. Third: if union is a substantial mode and something absolute, it is either in one extreme only or in both. Not the first, because each extreme is united, and they mutually refer to one another. It is necessary that there be a foundation in both for a relation to arise in both; but both refer to one another; therefore that mode exists in both, since it is the foundation of the said relation. Nor the second, because the same form, whether substantial or accidental, cannot simultaneously inform two subjects; and the adversaries themselves admit that union is found in only one of the extremes. Moreover, that absolute thing would have to be united to matter and form, as the Doctor infers (*8. Met. q. 4*) — and so it is not a union but something uniteable by means of a union, as in the humanity assumed by the Word, which the Doctor proves to be false in the passage cited and Faber develops effectively.

Assertion II. Union is a relation — not indeed intrinsically, but extrinsically accruing. The assertion is twofold, held by the Doctor in the passages cited above. The first part is proved, first, from Aristotle (*2. Phys. T. 26*), who calls matter and form simultaneously united relative beings. But they are not relative beings except through the union accruing to them — since they are substances that receive absolute being. Therefore union is a relation. Second: union is the relation and bond of the united things. For one thing is not united to itself but to another; therefore union is not a being "to itself" but "to another." But a respect "to another" is a relation; therefore union is also a relation. Third: the hypostatic union of the divine Word with the assumed humanity means nothing other than the relation of dependent human nature to the independent Word in the notion of personality, as the Doctor shows in the passage just cited. Therefore the union of matter and form also formally is nothing other than the said relation. The second part is argued: a relation intrinsically accruing arises necessarily when its extremes are posited. But when matter and form are

posited, the relation does not arise unless they are simultaneously joined; and if they are separated from one another, the said relation of union perishes.

Therefore union is not a relation intrinsically accruing but extrinsically accruing — one that does not arise from the nature of the extremes but upon the positing of some condition of presence, approximation, or other circumstance of each extreme. Furthermore, the union of an accident with the subject in which it inheres is a relation extrinsically accruing — for God can separate an accident from its subject and conserve it thus separated; and the same can be done with matter and form, as the Doctor rightly teaches (*4. d. 12. q. 1. §. Ad q. ante O*).

Therefore this union is numbered among the relations extrinsically accruing.

Objection I. Against the first assertion: what enters into the constitution and composition of something, if that thing is a substance, is certainly itself also a substance — as is clear with matter and form, which, since they constitute the composite substance, are themselves also substances. But by means of union the whole is constituted, which is a substance; therefore union is a substance, or rather a substantial mode. Confirmation: if union is not a substance, then it is an accident; but an accident cannot unite extremes except accidentally, and if it unites them accidentally, it makes what is one per accidens — which conflicts with (*8. Met. T. 15*), where the Philosopher establishes that from matter and form simultaneously joined there arises what is one per se. Response: I concede the major; I distinguish the minor. As a part entering into the essence of the whole — I deny; as a prerequisite condition — I concede. For it is necessary that the parts first be simultaneously united before they cause the whole — just as the approximation of a thing in place is necessary so that it be placed in place, and of fire to tinder so that the tinder be burned. Hence union is not an essential part of the whole but only the bond of the parts, as the Doctor rightly explains (*2. d. 2. q. 2. §. quantum ad 3. F*). To the confirmation: I concede the consequent for the subsumption; I say union unites the extremes substantially — both because its extremes are substances, from which it receives its denomination, just as generation, which is an action and therefore an accident, is denominated substantial from the substance that is generated by it; and also because its total terminus is a substance, namely the composite.

Objection II. Against the second assertion: from (*5. Phys. T. 10*), there is no per se motion to a relation. But if something were produced by means of union, there would be per se motion toward it, since it would be produced by the action of an agent. Therefore union is not formally a relation, being as it is in the genus of sterile things. Response: I distinguish the major. To a relation extrinsically accruing — I deny; to a relation intrinsically accruing — I concede. So the Aristotelian saying cited is to be explained. For there the Philosopher gives the example of the "where" — which is a relation extrinsically accruing, as Faber just cited notes above others.

Article III. How Many Unions There Are Between Matter and Form

On this question, as on the preceding one, certain philosophers — such as Suarez (*disp. 13 Met., sect. 9*) and the Complutenses (*1 Phys., disp. 6, q. 3*) — hold that there is only a single union connecting matter and form simultaneously. Others, however — such as Scotus (*2 d. 1, q. 5, § Secundum primam 5, and ibid. in Rep., q. 6, § Ad aliud, cum dicitur, and 8 Met., q. 4*), Mauritius (*ibid. in annot.*), and Mayr (*3 d. 1, q. 3*), to whom our recent Scotists also give their assent (*1 Phys., disp. 5, q. 10*), and Pontius (*disp. 34, q. 3, n. 31*) — hold that there is a twofold union between matter and form: one grounded in matter and directed toward form, and another grounded in form and directed toward matter.

Note and recall from what was said in the *Epitome* (*1 l. 1, q. 4, a. 8*) that one kind of relation is mutual, being real in both extremes — as the relation of similarity between two white things — while another kind is non-mutual, being real in one extreme and of reason in the other, as the relation of knowledge to its knowable object: in knowledge it is real, but in the knowable object it is of reason. The former relations are said to be of the first or second mode, being grounded in unity and plurality or in active and passive potency. The latter are of the third mode, being grounded in the measure and the measurable, as is evident from (*5 Met., cap. 15, T. 20*). Furthermore, recall from the same passage cited above that relation is subdivided into relations of equiparance, which share the same common account — such as relations of similarity, which are said to be of the same kind, and whose extremes are therefore equated, meaning they stand equally in that common account — and relations of disquiparance, which receive a diverse account. These are called relations of disquiparance because their extremes stand unequally with respect to the account that grounds them, as in the relations of paternity and filiation. For the relation of paternity is grounded in active potency, while the relation of filiation is grounded in passive potency. Nor do I think it should be omitted that there is a certain difference between mutual and non-mutual relations on the one hand, and relations of equiparance and disquiparance on the other. Although all mutual relations are either of equiparance or of disquiparance, as is clear from the examples already given, it does not follow validly that: it is mutual, therefore it is of equiparance — since it could be of disquiparance. The non-mutual relation, moreover, extends further than the relation of equiparance. Therefore in these matters the argument holds negatively but not affirmatively: it is not mutual, therefore it is not of equiparance.

Assertion. Between matter and form there exists a twofold union: one inhering in matter and directed toward form, and another in form, directed toward matter. This is the teaching of the Doctor in the passages cited above. It is established first from Aristotle (*2 Phys., T. 26*), who calls matter and form relatives, which cannot exist unless they are mutual. They are indeed relatives of the second mode, grounded in active and passive potency. For matter is passive and form is active. Therefore they are mutual relatives, and accordingly, just as a relation of union arises from matter toward form, so likewise a relation of union

results from form toward matter — and thus a twofold union is determined between matter and form, simultaneously united to compose the composite.

Second, the parts that are disposed and ordered together toward constituting a whole are united and mutually embrace one another in causing it. But matter and form are the essential parts of the whole, ordered toward causing it.

Therefore, if a real relation regarding the other part arises from one part, there certainly corresponds a relation from the other part in turn. And since from what has been said union is formally a relation, it clearly follows that the union is doubled in accordance with the doubling of the parts.

Someone might object, appealing to the case of the creature's real relation to God, while — according to Scotus (*1 d. 30, q. 2, M.*) — God has no real relation to the creature. Likewise, the humanity assumed to the assuming Word in the unity of hypostasis has a real relation, whereas the Word has no real relation to the humanity, according to the same Doctor (*3 d. 1, q. 1, § De primo. A.*). In the same way, it need not be surprising that from one part of the composite there should arise a real relation without one arising from the other. On the contrary: the reason why God has no real relation to the creature is that He is most actual and most perfect, and nothing new can come to Him, as the Doctor cited just above maintains. The parts of a whole, however, are ordered toward one another and mutually perfect each other. For just as matter is potential and capable of perfection, so form perfects, actualizes, and informs. Hence the same Doctor in the passage cited (*1 d. loc. cit., L.*) says that all the parts of the universe are ordered to the universe as a whole, because they are potential with respect to the form of order, which is the arrangement of like and unlike things, in the words of Augustine (*19 Civ., cap. 13*). Therefore matter and form regard one another with a reciprocal relation, and accordingly there is no parity between God and the creature, or between the Word and the humanity hypostatically assumed by Him, that would support the defense of a single union existing in only one of the parts of the whole.

Third, there are as many unions as there are terms toward which the union is directed, since union, being a relation, is multiplied in accordance with the multiplication of terms. But there are two terms capable of being united. For just as the union of matter is directed toward form, so the union of form in turn tends toward matter. Therefore the union is doubled in accordance with the duality of the parties. For there seems to be no stronger reason why the union should intrinsically affect one part rather than the other, since both are in fact united simultaneously. Therefore between them a mutual relation exists.

One might object with the Complutenses (*cited at the beginning of this article*) that there is a single union intrinsically affecting both parts simultaneously, just as one point unites and connects two parts of a continuum, one instant connects two parts of time, and one piece of glue connects two parts of a plank. On the contrary: it is incompatible that one and the same accident should be

simultaneously subject in two subjects, as is clear from what was established above. But a union is an accident, since it is a relation, as the Complutenses also concede. And matter and form are two distinct subjects, being two substances — though incomplete and partial ones. Therefore a single union cannot simultaneously affect both intrinsically. The analogies adduced above are of no help, since a point is something absolute and connects integral and non-essential parts — which is not the matter at issue here. The same must also be said of the rest, as will become clearer below. I add further that the union by which body is united and which inheres intrinsically in body cannot unite the rational soul, since the soul is spiritual while the body is material. That a bodily and material thing, whatever it may be, does not physically touch or intrinsically affect a spirit is indicated by Augustine (*12 in Gen., cap. 29*) after Aristotle (*1 de gen., T. 43 and following*), and it is treated explicitly by Doctor Scotus (*4 d. 44, q. 2*).

First Objection. Union is described as the bond and tie of two things, by which two extremes are bound and fastened together. Therefore there is only one union of matter and form as jointly connected. The antecedent is obvious; the consequence holds: for if the union were doubled, each part would have its own union, and therefore the two extremes would not be united by a single union, nor would they be joined together to cause the whole. First Confirmation: The divine Word and the humanity assumed by Him hypostatically are united by a single union in personal subsistence. Therefore the same must be said of matter and form as jointly connected. Second Confirmation: In natural and artificial things, a single union suffices to unite two extremes — just as one rope binds two bodies. Therefore matter and form are united by a single union so as to cause the composite.

I concede the antecedent and deny the consequence. In response to the proof of the consequence, I say that from each of the two extremes there arises a doubled relation of union, and this is called their bond — just as the relation of similarity is the assimilation of two similar things, and the relation of equality is the relation of two equal things, even though from each extreme there arises a real relation of similarity in similar things, and of equality in equal things. The reason is that, since they are mutual relatives, it is impossible that once all the extremes are posited and simultaneously conjoined, a relation of union should not result and intrinsically affect each of them. In absolute bonds, however, the case is different, and therefore a single bond and a single union suffices to join them — just as two parts of a line are coupled and united by the same point, as Aristotle teaches (*in the passage on quantity*), because the point, which is their bond and connection, is an absolute indivisible. To the first confirmation, I concede the antecedent and deny the consequence. The reason for the disparity is that the Word, being most actual and most perfect, cannot give rise on its part to a real relation of union toward the humanity assumed by it personally. But from matter and form, since they are parts and incomplete substances tending toward sharing in the perfection of the whole, if they are simultaneously joined,

a twofold relation of union necessarily arises, as the Doctor indicates (*3 d. 1, q. 1, § De primo. A. and Quol. 9, § De tertio. M.*). To the second confirmation, I distinguish the antecedent: in natural things that have essential parts, I deny it; in natural things that have integral parts, I concede it. The reason for the disparity is that essential parts are ordered to the whole, are perfected and completed by its perfection — but not so the integral parts, which when joined to the integral whole or separated from it do not possess greater or lesser perfection, as the Doctor says (*Quol. now cited, a little before N.*). As for artificial things, the parity does not hold, because either the bond is of the same entity as the united extremes — as when several ropes are bound by one rope — or if it is of a different kind, it is something absolute which the agent can connect to the separated parts and extremes, as two bodies are bound by a rope and two garments by a thread.

Second Objection. A union unites parts that already exist simultaneously, and does not presuppose that they are already united to one another — otherwise the union would be superfluous. But a relation of union presupposes extremes already simultaneously united, from which it subsequently arises, as is evident in any relation that results from the positing of extremes. Therefore the union in matter and form as jointly connected is not doubled.

I respond that the argument holds of a union that is something absolute interposed between two extremes capable of being united — and of this kind some examples were adduced above — but not of a relative union, which presupposes the extremes as fundamentally united but not formally, because it is the very thing by which they are formally united, just as similar things are formally assimilated by similarity, and equal things are formally equated by equality. This response is indicated by the Doctor (*2 d. 1, q. 2, § Ad 1. E.*), expressed by Lychetus (*ibid.*), and received by the twin Scotists (*cited above*).

Third Objection. The relation of union that emanates from the human body and tends toward the rational soul cannot connect the rational soul itself, because the material — such as that union of the body — cannot unite the spiritual, such as the rational soul, nor vice versa. Therefore only a single union should be posited, by which matter and form are simultaneously connected. I distinguish the antecedent: as subject, I concede it; as term, I deny it. For the relation of union on the part of the body is subject in the body and directed toward the soul. The relation of union on the part of the soul, however, resides in the soul as its subject and is directed toward the body as its term. That a spirit can be received in a material subject is evident from the soul, which is the act of the body (*2 anima, T. 6*).

Question VI. On the Composite of Matter and Form

Having treated above of the principles taken generally and specifically, and of their bond and union, I now treat chiefly of the whole constituted from those parts.

Article I. Whether the Composite Is One Per Se

All unanimously proclaim and affirm that the whole constituted from matter and form is one *per se*, although on the grounds for this some disagree, as can be seen in our two recent Scotists (*disp. 5 Phys., q. 11, a. 1*).

Note first that unity is a property of being (*4 Met., cap. 2, T. 3*). Therefore every entity is followed by its own unity, as Scotus observes (*8 Met., q. 4*). For if the entity is simple, it possesses simple unity; if composite, it shares in composite unity. Therefore matter, form, and the composite — being distinct entities — are endowed with their own proper and distinct unities, conformable and proportioned to themselves.

Note second that Aristotle sets out grades of unity (*5 Met., cap. 6*), as expounded by Scotus both there and in (*1 d. 2, q. 7, § Sed hic restat HH.*). I set forth and explain the more important ones that are most relevant to our purpose. Unity taken in the most general sense is divided into unity *per se*, which flows from the intrinsic account of the thing, and unity *per accidens*, which comes to the thing from without. Each of these is established as multiple by Aristotle in the passage cited. Unity by aggregation is the lowest, because many things are heaped together without any addition to the thing, as a pile of stones. Unity by order adds a relation and disposition by which many things are ordered to one, as all things in the world are one by order toward one God the creator, and an army is one by the ordering of soldiers toward one commander. Third is unity *per accidens*, which beyond order denotes a subject that is informed and perfected by an accidental form. Fourth is unity by composition, which belongs to the whole constituted from matter and form — and it is this that is being investigated in the present discussion. Fifth is unity by identity, which belongs to those things that are really identified, and by this unity a nature and its property are endowed. Sixth is formal unity, possessed by those things that share the same quiddity and formal account — as Peter and Paul in the account of the species are one and the same formally.

Assertion. The composite is one *per se*. This is the teaching of the Doctor throughout, most notably (*3 d. 22, q. un., § Contra ista. Sub. B., 8 Met., q. 4*), and Antonio Andrea (*ibid., q. 7*), following Aristotle (*2 anima, T. 7, 8 Met., T. 17*). It is proven first: what is constituted from that which is perfectible and that which perfects, substantially, is one *per se*. But the composite is constituted from that which is perfectible and that which perfects substantially — namely from matter, which is perfectible, and form, which is perfective. Therefore the composite is one *per se*. The major and minor are received as true by common consent of all philosophers.

Second: from essential and incomplete parts, of which one is *per se* a potency and the other *per se* an act, there comes to be one *per se*, as the common school teaches. But the composite consists of essential and incomplete substances, of which one is a potency — namely matter — and the other is act — namely form. Therefore the composite is one *per se*.

Third: from a primary act that gives primary and unqualified being, and a primary potency receiving that being, there comes to be one *per se*. On the other hand, from a secondary act that provides qualified being — such as an accidental form — and a subject receiving that kind of being, there comes to be one *per accidens*, as the Doctor rightly speculates (4 d. 11, q. 3, § *Aly concedentes*. Y.). But the composite comes to be from a primary and unqualified act, and from primary matter receiving that being, as experience makes plain. For from matter and igneous form, fire comes to be, which is one *per se*. Likewise, from matter and the form of a mixture there comes to be a mixture, which is one *per se*. Therefore it is rightly concluded that the whole is one *per se*. Nor is any other reason given except that matter is potency and form is act, as the Philosopher states in the passage cited above (8 Met., T. 15). To this Scotus adds (2 d. 12, q. 1, § *Dico igitur*. D.) that the reason why from matter and form there is constituted one *per se* is that they are the intrinsic causes of the composite. Not so from subject and accident, because the accident is extrinsic to the subject, and therefore from these there comes to be one *per accidens*.

First Objection. From two beings in act there comes to be one *per accidens* (7 Met., T. 49). But matter and form are two beings in act, especially in the school of Scotus, who teaches that matter has an entitative act, because it truly exists and subsists independently of form, from what was established in this book (q. 2, art. 5). Therefore a composite of matter and form is not one *per se*. I distinguish the major with Scotus (2 d. 12, q. 1, sub D.): from two things existing in formal and complete act, I concede; from two things existing in act, of which one is in entitative and incomplete act and the other in formal, incomplete, and imperfect act, I deny. The passage cited is thus expounded. For matter is an entitative act and form is a formal act, and each is an incomplete and imperfect act.

One might say that the subject is imperfect and yet perfectible *per accidens* by what can inhere in it, and that from subject and accident there does not come to be one *per se* — therefore neither from matter and form, and thus the response given above holds no ground. I distinguish the major: the subject is perfectible *per accidens* by something that can be received into it simply and intrinsically, I deny; according to a certain respect and extrinsically, I concede. This is drawn from the Doctor in (4 d. cit.). Hence from subject and accident there comes to be one *per accidens*, but from matter and form there comes to be one *per se*.

Second Objection. What are maximally distant cannot be united simultaneously and make one *per se*, as is evident with similar parts, which —

being proximate and of the same kind — make one *per se*. But dissimilar parts that are distant from one another and of diverse kinds make something less unified. Matter and form, however, are maximally distant, being of different kinds: matter is a potency and form is an act, and that potency and act differ greatly from one another Aristotle teaches (*1 anima*, T. 6). Therefore from these there is not constituted one *per se*.

I distinguish the major: things that differ greatly cannot make one by unity of identity — I concede, since this kind of unity is found between a subject and its property, which are really one. Things that differ greatly cannot make one by unity of composition — I deny. For even if they are greatly distinguished, provided they have a native proportion to one another, they are capable of being united and of causing one *per se*, and matter and form are such with respect to the composite, as the Doctor notes (*ibid.*, T.). As for what is raised about homogeneous and heterogeneous parts, I say there is a disparity, because those pertain to the integral whole, while these pertain to the essential whole, which is what we are discussing here. So the Doctor addresses it (*in Met.*, cited, at the end of the question).

Article II. Whether the Whole Is Really Distinguished from Its Parts

There are two chief opinions on this article that are diametrically opposed. The first is attributed to Averroes (*1 Phys.*, com. 9) and to other Peripatetics, followed and cited by Toledo (*this place*, q. 6), the Complutenses (*disp.* 6, q. 4, § 2), Suarez (*disp.* 36 *Met.*, sect. 3), Hurtado (*disp.* 6 *Phys.*, § 16), Arriaga (*disp.* 5, sect. 1), and the Nominalists are cited, as are most Thomists along with Thomas (*4 contra Gent.*, c. 81, ad 2, and 1 p., q. 77) and other places — all denying that the whole really differs from its parts. The second is that of the Subtle Doctor (*3 d.* 2, q. 2, § *Quantum ad 1, ostendo C.*, and in *Rep.*, q. 1, 6, *De primo dicit.*), Mayr (q. 10), John of Ovando (*ibid. in comm.*), Bonetus (*1 Phys.*, c. 4), the Parisienses (*fol.* 12, q. 1), Tataretus (q. 2, dub. 1), John of Magistris (q. 5), and others who affirm that the whole really differs from its parts. The Conimbricenses (*1 Phys.*, in cap. 2, q. 1) and not a few of the more celebrated Thomists cited by them also favor this view.

Note first that the title of this article can bear two senses: one asks whether the whole is really distinguished from its parts taken separately — what some call the syncategorematic whole — and all concede this, since it is certain that the whole really differs from any of its parts taken individually. The other asks whether the whole is really distinguished from its parts taken together and jointly — what some call the categorematic whole — and on this there exist the two opinions just recounted.

Note second that the whole is multiple: the universal whole, which has subjective parts of which it is predicated — as the genus is a universal whole predicated of its species. The integral whole, which consists of integrating and quantitative parts, and is itself twofold: one homogeneous, having parts of the

same kind, as fire and water; the other heterogeneous, having parts of different kinds, as an organic body composed of head, arms, hands, feet, and the rest. The essential whole, which has essential parts and is divided into the metaphysical whole, constituted from genus and difference — as a species, composed from the reality of the genus and the reality of the difference — and the physical whole, which coalesces from matter and form, as a human being consisting of body and soul. It is chiefly this latter that is at issue in the present controversy.

Note third that the third entity distinct from matter and form — which Scotus endeavors to introduce into his school in the passage cited above (§ *Quantum ad* 3. *E.*) — is called the form not of the part, as though another form were to come upon a form already pre-existing in matter informing and perfecting that form of the part, but rather the form of the whole, or the nature and quiddity of the whole composite. This is what Aristotle signifies (5 *Met.*, c. 2) and what Avicenna explains (*ibid.*, c. 1), saying that *equinitas est tantum equinitas* — that is, the nature of the horse, considered precisely and abstractly, is called equinity; and the nature and quiddity of man, considered in the same way, is called humanity. For it is the entire nature and essence of man, by which man is constituted formally in the being of man, essentially and quidditatively. Therefore the third entity is the entire nature of the composite, by which the composite itself is formally constituted in the being of the composite, essentially and quidditatively, and from which the properties and actions of the whole flow and proceed, as Aristotle indicates (1 *anima*, T. 64), cited by the Doctor (4 d. 49, q. 7, *ante* § *Respondeo*).

I further note that this controversy is so difficult and arduous to understand and judge that two men of great genius — namely Aristotle and Augustine — appear to leave it nearly undecided and under doubt. Aristotle speaks with hesitation in (1 *Phys.*, T. 17), raising the question whether the whole is the same as or differs from its parts. Augustine in turn (l. 1 *de moribus Ecclesia, contra Manich.*, c. 4) remarks that it is difficult to judge what man is — whether he is his soul, or his body, or something else distinct from both.

First Assertion. The essential whole is really distinguished from its parts simultaneously united and taken jointly. So Scotus (*ubi supra*). This is established first from Aristotle (1 *Phys.*, T. 17, c. 2), who, in proving the stated assertion, employs this reasoning: if the whole did not really differ from its parts taken together, the parts taken together would be identical to one another. But this is false, because the whole would be indivisible — therefore the parts would be as well. The force of the major is supported by the well-known axiom: things that are identical to a third thing are identical to one another. For if the whole and the simultaneously united parts entirely coincide, the whole is undoubtedly its parts — which Aristotle there introduces as an absurdity. Furthermore, the same Philosopher (2 *anima*, T. 2, c. 1, 7 *Met.*, *sum.* 2, c. 1, T. 7) divides substance into matter, form, and composite. But the members of a good division do not

coincide, since they are opposites, from what was said in the *Epitome* (1 l. 2, q. 7, art. 1). Therefore, since the whole is a substance distinct from matter and form according to Aristotle, and since he there affirms that the first substance is matter, the second form, and the third the composite — just as the third differs from the first and the second, so the whole differs from matter and form taken together from which it coalesces. Moreover, in (8 *Met.*, *sum. unic.*, c. 6, T. 15) he plainly states that the whole is something distinct from its parts taken together, saying that the substantial whole is not like a heap of stones, which beyond parts simultaneously united and aggregated is nothing else, but that it is something differing from them simultaneously united. These and similar testimonies of the Philosopher, collected and adduced by our authors, show that the doctrine set forth is conformable and consonant with the Peripatetic school, as Toledo, before others, observes (1 *Phys.*, q. 6). Nor does Augustine appear to disagree, who in (13 *Civ.*, c. 13) distinguishes the death of the soul, the body, and the whole man — not without reason, since in (*ibid.*, *the preceding chapter*) he asserts that man consists of soul and body (*ibid.*, cap. 15 and 24) and in (*lib.* 83, qq., q. 1), because the soul is other than truth, he infers that the soul is one thing and truth another.

Second, every effect really caused by a real cause is really distinguished from it, because the same thing cannot produce itself (2 *anima*, T. 47), nor is any greater absurdity conceivable than that the same thing causes itself and is simultaneously prior and posterior to itself with respect to the same thing. But the composite is a real effect, caused by matter and form (2 *Phys.*, T. 23, 5 *Met.*, 6 l. 2). Therefore it really differs from them when simultaneously united.

Someone might say that the argument concludes regarding extrinsic causes such as the efficient and final, but not regarding intrinsic causes such as matter and form. On the contrary: a cause taken generally, applying both to extrinsic and intrinsic causes, is defined as a principle, upon the existence of which something else follows — or as a principle that *per se* influences the effect, as even the adversaries themselves concede, particularly Hurtado (*disp.* 8 *Phys.*, sect. 1, § 1). Since, therefore, every effect caused by any cause — whether intrinsic or extrinsic — is something other than it, it plainly follows that it is really distinguished from the very cause by which it is caused. All the more so because between a real effect and its cause there is a real relation, which requires really distinct extremes. Therefore, since the whole is a real effect of matter and form, it is really separated from them. This argument is so compelling that one can scarcely find anyone who satisfies it, as John of Ovando (*cited above*) notes. Indeed, Hurtado (*disp.* 6, sect. 1, §§ 13 and 14), pressed by the weight of this argument, candidly admits that matter and form are not, properly speaking, causes. But this conflicts with Aristotle and the flood of other philosophers who number matter and form among the causes properly so called — which I will demonstrate evidently in its proper place.

Someone might say with the same author and others that the united parts do indeed cause the whole, not collectively — that is, not taken simultaneously, since in that case they would mean nothing other than the whole and would cause nothing, being themselves the very whole, just as parts simultaneously aggregated are a heap of stones — but distributively taken, that is, one united to another constitutes the whole — as stones taken individually, that is, one in relation to another, make a heap. On the contrary: a total and adequate effect requires a total and adequate cause, since the cause and effect observe their due proportion toward one another. But the whole is the total and adequate effect of matter and form simultaneously united, as I touched upon in the first note. Therefore it requires both simultaneously and collectively, not distributively — since an effect in its becoming, depending on two partial causes, cannot be produced unless those causes are simultaneously joined and simultaneously cause that effect, as is evident in the case of the intelligible species and the intellect simultaneously producing an act of understanding, and of father and mother simultaneously begetting offspring. Moreover, matter and form simultaneously joined, taken distributively, seem to do nothing other than the active and passive informing, which is not their effect — since they are substances, while informing is an accident or relation. But the composite is a substance, which is only produced by a substance. Therefore the distinction proposed is irrelevant to dissolving the objection stated. Finally: if one causes in relation to the other, either it really influences the effect or it does not. Not the latter, because then it would not be a true and real cause, as is assumed. Therefore the former — and thus the whole is really distinguished from its parts taken together, since it is something else produced and caused from them simultaneously united.

Third, a property is grounded in the whole as its adequate subject and belongs to it alone, as is evident in risibility, which belongs to man, not to his soul or body. But a property is not accommodated to the parts taken separately or jointly, as Aristotle indicates (*1 anima*, T. 64) — both because these are not perfect nor do they reside in the right line of a category, and because they are not the total and adequate term of generation or corruption, as the whole is (*1 Phys.*, T. 64 and *7 Met.*, T. 27). Therefore the whole really differs from them as simultaneously united.

Nor does it help to say that the property belongs to the simultaneously united parts insofar as they thus constitute the whole — since the union, which from what has been said is a relation, does not constitute a thing in perfect and absolute being, nor does it cause the whole, which is an integral and complete substance, since it belongs to the genus of sterile things. Therefore united parts are not the subject and ground of a property. I add that the union is indeed a condition presupposed for causing, but is not itself the cause of the whole and its property.

Fourth, among those things of which one can exist without the other, there is real distinction, according to Scotus (*2 d. 1, q. 4, § Contra istam*). But matter and form can exist without the whole existing — as in the three days of Christ's death, His humanity was truly destroyed because Christ truly died, yet His integral parts remained: namely His soul, which descended into Hell, and His body, which lay in the sepulchre incorrupt, according to (*Ps. 15: Non dabis sanctum tuum videre corruptionem* — "You will not allow your holy one to see corruption"). It must therefore not be denied that the whole is really distinguished from its parts taken together.

One might say with Ruiz (*1 d. 3, q. 1, in corp.*) that in the corruption of the whole it is only the union of the united parts that ceases, so that they persist separated from one another, as occurred in the death of Christ the Lord. On the contrary: in the death of a man, humanity is corrupted — which is a complete and absolute substance — and not the union, which is a relative accident, of which there is properly speaking no corruption or generation. Therefore in the destruction of the whole, it is not only the union of the parts that is dissolved, but the whole is destroyed — which is a third substance distinct from its parts taken together.

Second Assertion. The whole is not really the same as its parts transitioning into a third entity, since the parts remain in the whole itself. So the Doctor (*cited above, and 2 d. 22, q. 1*) and all his disciples, with the exception of Faber (*Theor. 21 and 3 disp. 9, c. 3*). It is proven first from Aristotle (*1 Phys., c. 7*), who teaches that matter and form are principles in the composite's actual being, because they persist in the composite. And in (*2 of the same work, T. 28, and 5 Met., cap. 2*), matter is defined as that from which something comes to be while it inheres, and form as the what-it-is of the thing. Therefore in the Lyceum of the Peripatetics, the parts do not pass into the whole but remain in it.

Second, parts that are the causes of the whole do not pass into its entity. For a cause does not pass into its effect. It is incompatible that a cause should become the effect and the effect the cause — for if it is a cause, it causes something, and therefore what is caused is not precisely the cause; otherwise the same thing would make itself and pass into itself. For this reason Scotus (*in 4 cit.*) says that matter and form are not caused, because they are the first principles and first causes of the thing. Therefore the distinction drawn by Faber between parts that do not pass into a third entity and parts that do pass into a third entity is opposed to Scotus and to the truth. Nor does his response help, saying that this is gathered from the passage cited (*§ Quintum ad 3 art.*) — since the Doctor teaches nothing there other than that the union is presupposed for the production of the whole, and that it is not the whole, since it is a relation, and therefore the whole is not the parts simultaneously united. As for what the same Faber adds — that Scotus admits that distinction, since in the solution of (*q. 2*) the Doctor wants the whole to be assumed first by the Word and the soul to be

the instrumental medium, with no other union of parts in the living Christ supervening or preceding — this proves nothing for him. For as I showed in (*Tract. de Incar., disp. 5, q. 1*), in Christ there were three unions according to Scotus, the union to the whole being prior and the union to the parts — that is, to the soul and body — being subsequent. Therefore the said Faber openly contradicts Scotus and reason.

Third, the parts that enter into and constitute the composite are not corrupted but remain in their real being and persist therein, as is evident for matter — which is ingeneratable and incorruptible — and for form, especially the rational soul, which is immortal. Therefore the parts do not pass or change into a third entity. Nor does it help to say with the said author that the rational soul changes with respect to its substantial being but not with respect to its substance, because in the body it has the operations of sensing and vegetating, which it does not exercise outside the body. For since the rational soul is immortal, it remains in the body in its being — therefore neither does it change nor does it pass into a third entity, since that composite of rational soul and body is something distinct from the soul itself, as is clear at a man's death, when the man is corrupted but not the rational soul.

Furthermore, to pass into a third entity is either to pass according to one's substance, or according to substantial being, or according to accidental being. Not the third, because on this there is no doubt. Nor the second — for either by substantial being he understands the principle of the operations of the whole, such as vegetation and sensation, and this is irrelevant to the controversy, since it is certain that the soul separated from the body does not carry out the operations it performs when joined to the body; or it means the first, since it cannot be denied that the substance of the soul remains incorrupt in the composite.

Fourth, in Faber's position there seems to be a contradiction: if the parts do not remain but become the whole, then a real distinction between parts and whole ought not to be admitted — since real distinction obtains between positive real extremes actually existing. But if the parts are not in the whole, they are not distinguished from it, and therefore it is superfluous to ask whether the whole is really separated from its parts. And if one responds that they are distinguished when they are only united but have not yet passed into the whole — on the contrary: when they are only united, there is no whole, because the union of parts is presupposed for causing the whole. And when the whole exists, there are no parts, as he himself admits. Therefore his distinction is empty and void.

Finally, it is true to say that the parts are in the whole — as soul and body are in a human being. Therefore they do not change or become the whole, but cause and constitute the whole as its intrinsic and essential parts persisting in it as long as the whole itself endures and persists.

Third Assertion. Between the united parts and the whole there is a positive and mutual real distinction. This assertion contains two claims. The first part is derived from Scotus (3 d. 2, q. 2, § *Quantum ad 3. F.*, and d. 22, q. un., D., § *Quantum ergò*) — against Faber (*cited above*), who admits only a negative distinction. It is established as follows: between positive real entities that are really distinct, there is a positive real distinction, since this derives its entity and denomination from them. But the stated distinction obtains between positive real extremes that are really distinct — namely the united parts and the whole caused from them, as I showed above. Therefore between the said parts and the whole there is interposed a positive real distinction.

Moreover, what essentially depends on another differs from it by a positive real distinction, as is evident in the creature, which essentially depends on God and is really and positively distinguished from Him. But the whole essentially depends on its parts, as Scotus asserts in the places cited above. Therefore it is also really and positively distinguished from them.

The second part is gathered from the Doctor (*ubi supra*), which is systematically maintained by Fuentes (1 *Phys.*, q. 6, *dif. un.*, art. 5) with others cited by him, against Trombetta (*Tract. Form.*, quarta part., art. 4, *concl.* 2) and certain others among the earlier Scotists. It is proven as follows: a relation pertaining to the second mode of relatives is mutual (5 *Met.*, c. 15, T. 20). But the distinction between the united parts and the whole is a relation of the second mode, obtaining between a cause — which is the parts — and what is caused from them — which is the whole. Furthermore, the whole, since it is finite and limited, is capable of relation and real distinction, just as the united parts are. Therefore if from the side of the parts there arises a real distinction and relation toward the whole, in the same way from its side there results a real distinction and relation toward the parts that concause it.

First Objection, against the First Assertion. Aristotle (1 *Phys.*, *sum.* 2, c. 3, T. 17) seems not to distinguish the whole from the parts taken together. And in (4 *Phys.*, T. 23) he plainly says that the whole is nothing other than its parts. And in (2 *anima*, T. 7, c. 1) he states that body and soul are one. And in the same work (T. 10) he adds that just as the eye is the pupil and sight, so soul and body constitute the animal. The Fathers corroborate this, especially Augustine (7 *Trin.*, c. 4): body and soul are the whole man. And in (*in Ps.* 56): man himself is soul and flesh. And in (*in Ps.* 145): the whole man, that is, spirit and flesh. Consonant with this is that saying of Athanasius in the Symbol: *Sicut anima rationalis et caro unus est homo: ita Deus et homo unus est Christus* — just as the rational soul and flesh are one man, so God and man are one Christ — and from the person of the Word and the humanity assumed by Him there does not result something third really distinct from them. Therefore neither from rational soul and flesh is there caused something really distinct from them. Boethius adds (*l. de Trin.*, c. 3): any whole means nothing other than its united parts. Dionysius (*de caelesti hierar.*,

cap. 4) favors this, calling death in us not the destruction of substance but the separation of united things. Augustine himself (*in Ps. 48*) asserts the same: *Mors est separatio animae a corpore* — death is the separation of the soul from the body. And in (*tract. 43 in Ioan.*): death is the abandonment of the body, the laying down of a heavy burden. Nor is that saying of Damascene irrelevant (*3 fidei, c. 16*): what He once assumed He never laid aside. But if the whole were to differ from the parts at Christ's death, He would have laid aside humanity — and thus He would then have laid aside something that He had at another time assumed.

I respond: the first testimony of the Philosopher actually works against rather than for the objection — since the same author introduces as an inconvenience the identity of the whole and its parts, as the Canonists (*1 Phys., q. 5*) and John of Magistris (*ibid., Scibile 2*) note. Nor does Tataretus dissent (*q. 2, dub. 1*). To the second, I say it is to be taken causally, not formally, and that this is the sense intended by Boethius, as our recent authors (*ubi supra*) plainly convey. The response of Trombetta (*cited*) seems to amount to the same thing when he says that the parts taken together are not other than the whole — meaning that they integrate and constitute the whole, and that nothing other than the parts themselves causes the whole. To the third and fourth, the same response holds, since they are taken in the same sense. And no other reason need be sought for why from matter and form there comes to be a whole, except that the one is potency and the other act, as Aristotle clearly explains (*8 Met., T. 15*). The same response serves the passages from Augustine and Boethius cited above. And it can be added that those texts are to be understood not by formal predication but by containment — meaning that man, beyond body and soul as essential parts, contains nothing else. As for Dionysius and Augustine cited again, it suffices to say that they are speaking against those who hold that the soul of man perishes at his death. For this reason Ecclesiastes (*3*) says: *unus est interitus hominis et iumentorum, et aqua utriusque conditio* — the death of man and beast is one, and the condition of both is the same. To turn them back from this error, the said Fathers assert that at the death of a man the soul is separated and parted from the body, and that his death is the separation from the body. As for Athanasius, he can be explained thus: just as from rational soul and flesh there comes to be one *per se* supposit and person, so from God and man there is had one supposit and one person. Finally, what Damascene asserts is interpreted by the Doctor (*3 d. 2, q. 7, § Ad argumenta. 1.*) as referring to the essential parts — namely soul and body — never laid aside by the Word.

Second Objection. What is absolute and really distinguished from another can be separated from it, at least by divine power, as Scotus repeatedly notes. But the whole is absolute and really distinguished from its simultaneously united parts, according to the same Doctor. Therefore the whole can exist by divine power without its parts. But it is incompatible that the whole should exist without its essential parts — as that a man should exist without soul and body. Therefore it is impossible for the whole to really differ from its parts.

I distinguish the major: if there is no essential dependence, I concede; if there is essential dependence, I deny. In accordance with the distinction of the major, the minor must be distinguished. For the whole essentially depends on its parts, which are its intrinsic, essential, causative, and constitutive principles. Therefore, although it really differs from them, it cannot exist without them nor be separated from them. This is evident in the creature, which really differs from God the creator, yet on account of the essential dependence it has on Him, it cannot exist without Him. Likewise, a predicamental relation really differs from its own foundation, from which it nevertheless cannot be segregated on account of the essential dependence it has upon it. This response is drawn from the Doctor (*2 d. 1, q. 5, § Ad q. M., and 1 Rep., d. 1, q. 2, § Item quaecumque*), and is embraced by Antonio Andrea (*7 Met., q. 18*) and the Canonist (*q. 5, 1 Phys., art. 2*).

One might insist that an accident essentially depends on the subject in which it inheres, and yet God can really separate and divide the one from the other. Therefore the same must be said of the whole and its parts. The parity must be denied, since the dependence of the accident on its subject is extrinsic, whereas the dependence of the whole on its parts is intrinsic. Therefore the whole is inseparable from its parts, but an accident is not inseparable from its subject, as Scotus indicates (*4 d. 12, q. 1, ante § Ad argumentum. N. O.*).

Someone might say with Faber (*cited*) that this essential dependence of the whole on its parts is nowhere taught by Scotus. For this reason the same author adds that Scotists are deceived in thinking the same applies to efficient, formal, and material causes and their effects. On the contrary: first, even if Scotus had not transmitted this kind of dependence, the response given would not thereby be false — for an argument from negative authority does not conclude. Furthermore, I find this dependence in his writings, particularly in (*1 Rep., d. 1, q. 2, § Item quaecumque, and 2 d. 1, q. 5, § Ad q. M., and 4 d. 12, q. 1, § Ad q. N. O., and § Ad argumenta, near the end, and 3 d. 2, q. 2, § Quantum ad 1., and 2 d. 12, q. 1, § Dico igitur. C., and a little before, § Est igitur videndum.*). From these it is clear that Scotus admits intrinsic and essential dependence between the whole and its essential parts, and at the same time points out the difference between efficient causes on the one hand and material and formal causes on the other. Between the efficient cause and its effect there is an extrinsic essential dependence; but between the material and formal cause and their effect there falls an intrinsic essential dependence. Faber's distinction, however, between parts that do not pass into a third entity and parts that do pass into a third entity, is supported neither by the authority of Scotus nor by reason, and is therefore rightly rejected as novel and empty by all Scotists.

Third Objection. The whole cannot in any way be conceived without its parts, since the whole is that which consists of parts. Therefore the whole does not really differ from its parts. I concede the antecedent and deny the consequence,

as is evident in the case of a relative, which cannot be conceived without its correlative and yet really differs from it.

One might say, from the passage *c. De ad aliquid*: it is the property of relatives that one is understood along with the other. But an absolute thing, such as the whole, just as it does not depend on another in being, so also it does not depend on another in being understood. Therefore if — as I have conceded — the whole cannot be understood without its parts, neither can it exist without them, and thus it is not really distinguished from them.

I say that a relative differs from its correlative in this: a relative always co-requires its correlative as something extrinsic and as its term. But an absolute either co-requires nothing else, or if it does co-require something, that something is intrinsic to it — as the whole co-requires its parts, which are intrinsic and essential to it.

One might press further: if the parts belong to the essence of the whole, then they do not differ from the whole — since the essence of a thing does not differ from the thing of which it is the essence, as rational animal, which is the essence of man, does not differ from man himself. For nothing is more intimate to a thing than its essence. But the parts are the essence of the whole, since the whole is defined as that which has parts. Therefore there is no distinction between the whole and its simultaneously united parts.

This must be addressed by a distinction: the united parts are the essence of the whole *in obliquo*, I concede; *in recto*, I deny. For man is not body and soul, but a being consisting of body and soul. Therefore the whole is not the parts but the having of parts, since it includes the parts and is something third distinct from them.

Fourth Objection. Either the whole is simple or composite. But it is not simple, since it consists of parts. Therefore it is composite. But a composite essentially includes its parts. Therefore it is not really distinguished from them.

I distinguish the subsumption: the whole includes its parts as its intrinsic causes, I concede; as its essence and quiddity, I deny. Since the whole is caused from them, it is consequently something else, really differing from them.

One might say: either form alone causes the whole, or matter alone, or both together. But none of these can be said. Therefore the parts are not the causes of the whole but are the whole itself. The major is evident from the sufficient enumeration given. The minor is plain: not the first, because since form is a partial cause, it concurs only partially in effecting the whole. Nor the second, both for the same reason and because matter is purely passive. Nor the third — for in man there is a rational soul and a body, and thus his composite would be at once bodily and incorporeal, material and spiritual, mortal and immortal, divisible and indivisible, which involves a contradiction.

I say that each causes the whole in its own genus, and no contradiction follows in man. For since the rational soul is incorporeal, immaterial, immortal, and indivisible, the aforesaid predicates are affirmed of man by reason of it; while by reason of the body the other predicates are affirmed of him. For man is constituted from spirit and body. Yet he is said absolutely to be corporeal, material, mortal, and divisible, as Mayr notes before others (*Quol. 10, ad finem*) — because the effect follows the weaker part, and it is commonly held in logic that the conclusion follows the weaker part. Therefore man *per se* and directly belongs to the category of corporeal substance.

Fifth Objection. What comes to a thing already constituted in its being makes one *per accidens*. But the whole comes to the parts already constituted in their being and simultaneously united. Therefore if the whole were something really distinct from its parts, it would be one *per accidens*, which conflicts with Article I of this Question.

I concede the major and deny the minor. For the whole is not adventitious to the parts but is intrinsically constituted from them, truly caused, perfected, and completed. One might insist: what comes to a being in act is accidental to it. But the whole comes to matter actuated by form. Therefore it is accidental and adventitious to it. I concede the major and deny the minor — since, as I have said, the whole does not come to the parts but is caused from them.

Fifth Objection, against the Second Assertion. Matter and form constitute one *per se* (8 *Met.*, T. 15). Therefore the whole does not really differ from the parts. The consequence holds because real distinction falls between two things; but matter and form make the composite, which is one. Therefore they pass into its third entity. Confirmation: it is incompatible that something should be really separated from that which intrinsically and essentially constitutes it — for if it is intrinsic to it, it is not other than it itself. And if it is other, it is clearly extrinsic to it. Therefore it is rather to be said that the parts pass into the whole than that the whole is really distinguished from the parts.

I concede the antecedent and deny the consequence. For matter and form are two constituting principles and two partial causes integrating one total cause, while the whole is one constituted and principiated thing, one effect caused from them. That a cause and its effect really differ is the common teaching of philosophers.

To the confirmation, I say that the objection concludes concerning parts and extrinsic causes such as the efficient cause — not concerning parts and intrinsic causes such as matter and form, which cause and essentially constitute the whole, upon which it depends in becoming and in being, and from which it is inseparable even by divine power, as the Doctor indicates (1 *d.* 17, q. 2, *sub CC.*).

One might say: the parts also depend on the whole, and yet they can be separated from it. Therefore the same must be said of the whole. The parity

must be denied — for the whole depends on the parts with a dependence that is unqualified, while the parts depend on the whole with a dependence that is qualified. For this reason the latter can be separated from it but not it from them, as Vorillong rightly saw (3 d. 33, art. 3, ad 2) and Aristotle touches upon (6 Top., cap. 3, 1 pol., cap. 2). For when the parts are corrupted the whole must be corrupted; yet when the whole is corrupted it is not necessary that the parts be corrupted.

Article III. Whether the Integral and Per Accidens Whole Is Distinguished from Its Parts

Among Scotists I find very great discord and disagreement on this article. Some — such as Mastrius and Bellutus (*disp.* 5, q. 13, art. 2) and Pontius (*disp.* 35, q. 2) — deny that any whole, whether integral or *per accidens*, is really distinguished from its parts taken together. Others, from whom Fuentes (q. 6, dif. 2, art. 7) does not seem to be far distant, concede that both of the aforementioned wholes really differ from their parts taken together. Still others — such as Sirectus (*Tract. form., ad finem, art. 4, partialis*), Vallo (*ibid.*), Mayr (3 d. 2, q. 10, in calce), Tataretus (1 Phys., q. 2, dub. 2), and the Parisienses (*ibid.*, q. 4, fol. 13) — admit that the integral whole is really distinguished from its simultaneously united parts, but deny this of the *per accidens* whole.

First Assertion. The integral whole is really distinguished from its simultaneously united parts. So Scotus (2 d. 16, q. un., § *Alia opinio. F., and ibid. in Rep., § Item si sint partes, and 3 d. 22, q. un., ante § Sed quid logice, sub L.*). It is proven first from Aristotle (7 Met., T. 60), who says that the syllable *ba* is not A and B but something distinct from A and B — for if A and B are separated from one another, they indeed remain free, but the syllable does not. Likewise, flesh is not earth and fire from which it is composed, but something distinct from them — for if it is dissolved, those elements indeed remain, but flesh does not, as the Doctor excellently explains there. Mastrius and his colleague (*cited*) respond that those testimonies are to be taken of the integral whole distinguished from its parts taken separately, not from parts taken jointly. On the contrary: that is beside the point, as the same authors along with all the rest candidly confess — and they themselves together with Scotus adduce that same passage of Aristotle to prove that the essential whole is really distinguished from its simultaneously united parts, as is clear from their own first argument in (*art. 1*). Therefore they do not satisfy the passages of the Philosopher, and appear rather to contradict themselves in trying to solve them.

Second, this proposition is denied by no one: the integral whole is composed from parts. Either in this proposition the whole stands for its parts, or for something else. If the latter, then it is distinguished from them. If the former, then the same thing is composed from itself — that is, parts from parts — which is absurd. The authors cited above respond that the integral whole is not distinguished from its united parts — or from its parts taken with the union —

but that it is well distinguished from parts taken separately. But they do not resolve the argument; they beg the question. For what is in dispute is precisely whether the integral whole differs from its parts taken jointly or not. All the more so because the said authors in (*art. 1, first argument*) attack this response as void and empty.

Third, the integral whole is either homogeneous or heterogeneous, and each really differs from its parts — and indeed the heterogeneous, such as man, about which Scotus provides an example (*3 cited above, below L.*), and likewise the homogeneous, such as flesh, about which the same Doctor with Aristotle (*7 Met., T. ult.*) provides an example. Therefore the integral whole is distinguished from its parts.

Second Assertion. The quantitative whole is also something other than its parts. This is derived from Scotus (*2 d. 3, q. 4, § Ad primam rationem, sub I., and 3 in the passage cited above*), followed by Sirectus and Vallo (*ubi supra*), against Trombetta and the twin Scotists (*cited*). It is established first: there is a distinction between the universal whole, which is divided into subjective parts, and the quantitative whole, which is divided into quantitative parts. The universal whole is truly and correctly predicated of its subjective parts — as animal of man and beast — while the integral whole is not at all predicated of its parts, since this part of water is not predicated of the whole water — it is truly a part of the water, not the whole water. Therefore the quantitative whole is something other than its parts. Moreover, the universal whole, since it is identified with its parts, is rightly predicated of them.

Second, a subjective part cannot exist without the universal whole — as Peter cannot exist without man. But a quantitative part can exist without the quantitative whole — as this part of water can exist without the whole water. Therefore the quantitative whole is distinguished from its parts. Furthermore, the quantitative whole is either continuous or discrete. The continuous is evidently distinguished from its parts from what has already been proven. The discrete is also shown by Aristotle (*5 Met., c. 14*): twice three is not six, but once six is six. And Scotus (*ibid., in exp. tex.*) concurs.

Third Assertion. The *per accidens* whole is not distinguished from its parts. So the Doctor (*3 d. 2, q. 2, § Quantum ad 3, sub E.*), from whom John of Magistris (*1 Phys., q. 5, Scibile primo*) departs. It is proven first: a third thing resulting from two things that cause it is either a substance or an accident. For nothing mediates between these two members, since being is adequately divided into substance and accident (*5 Met., T. 14*). If, therefore, the *per accidens* whole were something other than the subject and the accident inhering in it, it would be either a substance or an accident. But it can be neither — otherwise a substance would be a part of an accident and an accident a part of a substance, which involves the contradiction that a substance would inhere in a subject and an accident would subsist *per se*.

Second, the subject and accident that make one *per accidens* are each complete and perfect in their own genus. Therefore they do not tend toward causing a third thing distinct from them. For to do that, they would have to be imperfect and incomplete, as is evident from matter and form causing the composite. Furthermore, the constituting principles of something other than themselves are of the same genus and category, as is clear by induction from the principles of the universal whole — which are matter and form — and from the principles and parts of the integral and quantitative whole. But the subject and the accident inhering in it are of different genus and category.

First Objection, against the First Assertion. If the integral whole were something other than its parts, then matter — which according to the Doctor (2 d. 32, q. 2, *Respondeo. D.*) consists of integral and entitative parts — would be generable and corruptible. For if it were divided into parts, its third entity would be corrupted; and if those same parts were reunited, its third entity would be generated — which conflicts with (1 *Phys.*, T. 82). Therefore the integral whole does not differ from its parts. Confirmation I: if a drop of water were to fall into the sea, a new entity of water would be generated spread through the vast expanse, and if a drop were to be taken from that same sea, a new entity of water would perish — which is extraordinary and unheard of. Confirmation II: numerically the same thing could be naturally reproduced — for if the divided parts of water are rejoined, the whole water that existed before will return. This seems absurd and unreasonable.

I respond by distinguishing the major: simply, I deny; according to a certain respect, I concede. That is said to perish simply, as the Canonist notes (1 *Phys.*, q. 9, art. 2, *dub. 1*), which is corrupted with respect to its parts and whole — as in the death of a brute, the brute perishes, as does its soul and body, or at least some part of the whole is destroyed, as in the death of a man, where his body is corrupted but his soul persists. But what ceases to exist with respect to its third entity while its parts nevertheless remain is said to be corruptible according to a certain respect. As in our present matter: if matter were divided into its substantial and entitative parts, it would be corrupted according to a certain respect. Nor is this surprising, since matter itself is commonly said to be corruptible and generable *subiective*, even if not *obiective*. And the parts of a nourished individual ebb and flow with respect to material and formal being, as the Doctor teaches (4 d. 44, q. 1).

Someone might say: if the whole is corrupted even though its parts remain, then it is corrupted simply — both because the whole is more excellent than its parts, and because once the whole is destroyed, the thing is said simply to perish and be destroyed. Thus Christ died absolutely because His humanity, which was His third entity, then perished, even though all His parts remained incorrupt. Therefore matter would be simply and absolutely corruptible and generable.

The consequence must be denied. The reason is that if the parts remain when the whole is destroyed, they can still be reunited by an agent, and since they are integrating and constituting principles, they can again cause the whole — as is evident with a whole body of water, which if divided into its parts loses its totality, yet because those same persisting parts can be reunited by an agent and cause the whole water as it was before, it is therefore said to be corrupted according to a certain respect. But if once the whole is destroyed, a part or parts do not survive but also perish, then the whole cannot return — and for this reason it is not unreasonably said to be corrupted simply. Nor does any other difficulty seem to arise, except perhaps about a name — whatever Mastrius and his colleague (*cited*) may contend. To Confirmation I: given the hypothesis, a drop of water would be united to the sea as a part is united to a whole, and a part of flesh added through nourishment is joined to the pre-existing flesh, as the Doctor teaches (*4 d. cited, passim proximé cit.*). To Confirmation II: the major is conceded, on the authority of the same Doctor (*d. 43, q. 3, § Quintum ad istum. E.*).

Second Objection. The chief reason the Scotist school defends the essential whole as being something other than its parts is that the essential parts cause the whole itself. But integral parts do not cause the integral whole — for one of them is not in the mode of that which is perfectible, and the other in the mode of that which perfects, as matter and form are. Therefore the integral whole does not differ from its parts.

I concede the major and deny the minor, from Scotus (*2 d. 16, q. un., § Alia opinio. F.*), who writes as follows: because integral parts always make a certain whole, something other than any of the parts, through something formally concurring.

Third Objection, against the Second Assertion. If the quantitative whole were posited as something other than its parts, a new quantity would be lost in its division, and in its opposition and continuation a new quantity would be acquired. But this contradicts Scotus (*4 d. 12, q. 1, § Ad quest. respondeo. K.*), who affirms that in the division of parts the relation of the united parts perishes, and in their apposition this relation of united parts is acquired. Therefore, according to Scotus, the quantitative whole does not differ from its simultaneously joined parts.

I respond that Scotus affirms one thing there without denying another. He affirms that in the division of a continuum the aforesaid relation of parts perishes, and in the apposition of parts it is acquired. But he does not deny that the quantitative whole is something other than the parts. On the contrary, before (*K.*) he plainly and openly shows that in the continuous whole there is a third entity differing from the parts, in these words: *Illa autem tertia entitas quae praefuit, non manet nunc* — that third entity which was present before no longer remains now. He also clearly acknowledges the same entity in the places cited in the second assertion.

Fourth Objection. If the quantitative whole also differs from its parts, then three would be four, and two pounds would be three pounds, and other inconveniences would follow that Tataretus (*cited*) recounts — since the number three, beyond its three parts, would include a fourth entity by which it is constituted in the being of three, and beyond the duality of two pounds a third entity distinct from them would be added.

The consequence must be denied. For that third entity of the number three is not counted as a distinct part — just as the common account and nature is not reckoned as something distinct from the particulars. For it does not hold to say: there are three men, and those three share in the common account and nature of man; therefore that common nature is distinguished from the particulars — since common things are not numbered in the enumeration of particulars, as Scotus (*1 d. 24, q. unic., D.*) and Mauritius (*q. 24, univ., § de tertio*) touch upon. The reason that can be given is that this common account is the essence and nature of the particulars, which can make no number among them.

Fifth Objection, against the Third Assertion. Every composite is distinguished from the parts of which it coalesces. But the *per accidens* whole is composed from subject and accident, from which there comes to be one *per accidens* — and each of these is in the mode of potency, as the subject, and the other — namely the accident — is in the mode of act, as both Aristotle (*8 Met., T. 15*) and Scotus (*ibid., in exp. Top.*) acknowledge. Therefore the *per accidens* whole is something other than its parts.

Confirmation I: every change has its term by which it is specified. But alteration is a change (*5 Phys., cap. 4*) whose term is the *per accidens* whole, which is therefore to be distinguished from its parts. Confirmation II: Scotus (*3 d. 2, q. 2, § Quantum ad 3, below E.*) writes that the *per accidens* whole is one something, just as the essential whole is — for just as the latter comes to be from potency and *per se* act, so the former comes to be from potency and *per accidens* act. For this reason he had just previously premised that the *per accidens* whole is not its own parts, as the aggregate whole is. Hence Aristotle (*7 Met., T. 11 and 12*) argues that a white man, who is a *per accidens* whole, is something one. Therefore it is something other than its parts.

I distinguish the major: a composite composed *out of* these, I concede; a composite composed *with* these, as the *per accidens* whole is, I deny. So responds the Canonist (*1 Phys., q. 5, art. 4*) and the Parisienses (*q. 3, fol. 13*). To the second point.

To Confirmation I: I say that alteration is specified by its formal term — so when whiteness is placed in a wall, the action is called a whitening (*5 Phys., T. 5*) by the whiteness, which is its formal term.

To the confirmation: I say that there is a parity in this — that just as matter is perfected by form, so the subject is perfected by the accident received in it —

but a disparity in that form perfects matter simply, while an accident perfects the subject in a qualified respect. From the former there results a third thing, but not from the latter, for the reasons assigned in the third assertion. Furthermore, the *per aggregationem* whole has minimal unity, from the Doctor (*1 d. 2, q. 7, § Sed hic restat.*). And the *per accidens* whole adds above that the unity of information. Hence because of this union and unity, the Philosopher (*cited*) says that the latter is not its parts even taken together — but the former is. Scotus, however, cites the example rather of the aggregate whole than of the *per accidens* whole, because the former is better known and clearer than the latter.

Book III. On Nature and Art

Aristotle treats of Nature and Art in *2 Phys.* — first of Nature, then of Art, since Nature precedes Art, which Art itself imitates.

Question I. On Nature

Article I. What Nature Is

The Philosopher in *2 Phys., cap. 1* warns that it need not be debated whether nature exists — since experience makes it evident and it is self-evident that there is natural motion, whose principle is nature. If anyone wished to prove that nature exists, he would be like one blind from birth who tried to demonstrate evidently to those who see that visible colors exist. For it is clearer to those who see that colors exist than any arguments could establish. Therefore the question of whether nature exists is set aside, and the inquiry turns to what it is.

Note first from Aristotle (*5 Met., cap. 4, T. 5*) and Scotus (*ibid., in com.*) that nature is taken in many senses. First, for God, the parent and maker of all things — as Augustine (*15 Trin., cap. 1*) takes nature — and this is by some called *natura naturans*, while the thing created by God is called *natura naturata*, as can be seen in the Conimbricenses (*2 Phys., q. 1, art. 1*). Hence the world founded by God is by some called the work of nature and intelligence.

Second, for the essence of any thing — thus the Doctor says (*2 d. 1, q. 5, § Contra ista. 1.*) after Aristotle (*7 Met., T. 41 and 42*): a definition is a statement distinctly unfolding the nature of a thing. In the same way, the faithful say that in the Divine there is one nature, and that the union of the divine Word was made not in the nature but in the person of the same Word.

Third, for the entire collection of created things — in which sense something is said to happen or to be in the nature of things, and what surpasses the powers of creatures is called a miracle. Augustine makes mention of this usage (*l. 26 contra Faustum, cap. 4, and l. 29 contra eundem, cap. 7*): if God does certain things

contrary to the customary course of nature, they are called great deeds and wonders; but those that do not exceed the manner and use of nature are called natural.

Fourth, for nativity, which is the generation of living things. For nature derives from nourishing, as Scotus (*recently cited*) notes. Since generation proceeds from an internal principle, the name of nature arose to designate the internal principle of any thing, as is evident in the Philosopher (*cited just above*). Therefore nature, properly speaking — about which we treat in the present discussion — is taken for the origin and intrinsic principle of motion and rest.

Note second that nature is defined in 2 *Phys.*, *cap. 1, T. 3* in these words: nature is the principle and cause of motion and rest in that in which it is, primarily and *per se* and not according to accident. It is explained with respect to all its parts. The word *principle* is placed as the genus. *Cause* is added on account of privation, which is indeed a principle but not a cause. *Of motion, of rest* is added — understand this disjunctively, with *or*. For some bodies, such as the heavens, are always in motion; others are always at rest, such as the earth. It can also be taken conjunctively — for all natural things are suited and capable of motion and rest, even though in act some only move and others only rest. *In that in which it is* is said so as to differ from an extrinsic principle such as the efficient cause. *Primarily* is added on account of accidents, which in some way contribute to motion and rest — as gravity in a heavy thing and levity in a light thing — and it designates nature as the radical and principal principle of moving and resting. *Per se and not according to accident* is added on account of art, which is the principle *per accidens* of motion and rest — as a bench is moved or rests not insofar as it is a bench or a work of art, but insofar as it is a natural body or wood, in which nature inheres as the aforesaid principle of moving and resting.

Assertion. The proper and genuine definition of nature is the one just given and explained above. The Doctor accepts it (2 *d. 2, q. 10, § Respondeo. F.*) together with the entire Peripatetic school. It is established by the common medium. That is a good definition in which the proper genus and difference are assigned, from what was established in the *Epitome* (1 *l. 1, q. 7, art. 2*). But this definition is of this kind — for the word *principle* is in place of the genus, and the remaining parts hold the place of the difference. Therefore it is a sound and exact definition. Furthermore, it belongs to everything contained under the defined term and to nothing else, and contains nothing superfluous or deficient — as the laws of good definition require. Therefore it is rightly given.

First Objection. An absolute thing is not defined by a relative, since they are opposites. But *principle* is a relative, and nature is an absolute being, since it belongs to the genus of substance. Therefore nature is ineptly defined by *principle*.

I distinguish the major: formally and essentially, I concede; fundamentally and materially, I deny. Thus matter is defined by *potency* and form by *act*, which are relatives, as Aristotle shows (*2 Phys.*, T. 26).

Second Objection. The same thing cannot be the cause of opposites — especially privative opposites — as is evident (*4 Meteor.*, *sum.* 2, *cap.* 3). But motion and rest are privative opposites, since rest is the privation of motion. Therefore nature is wrongly defined as the principle of motion and rest.

I concede the major. I distinguish the minor: if rest is taken as the privation of motion, I concede; if it is taken for consisting in a place, as it is taken in the present context, I deny. This response is derived from Scotus (*4 d.* 48, *q.* 2, § *Ad argumenta.* O.) and touched upon by Augustine (*2 de lib. arb.*, *before cap.* 8).

Third Objection. A correct definition applies to all things contained under the defined term (*6 Top.*, *cap.* 4). But the definition given is not of this kind — both because it does not belong to the rational soul or to angels, which are separate forms, and also because it does not apply to the earth, which stands forever (*Eccl.* 1), nor to the heavens, which are always in motion. Therefore another definition of nature should be assigned.

I concede the major and deny the minor. In response to its proof, I say that the rational soul is nature, since it is the true form of the human body — which, although it can exist separated from the body, nevertheless always has an aptitude and inclination toward it. An angel, however, is not a physical form as a part of a body, but is a complete and perfect nature, and therefore the definition of nature does not suit it. As for what is said of the earth, I say that even though in fact it rests, motion is not incompatible with it, since it has in itself the principle of motion, which is nature. In the same way, although the heavens always move, they can nevertheless rest — as they rested in the time of Joshua until the battle against Gibeon was completed (*Jos.* 10), and after the day of judgment they will no longer be moved. Therefore the heavens and the earth have within themselves the principle of moving and resting.

Article II. Whether Nature Is a Passive Principle

Philosophers are divided three ways on this article. Some — such as Vallesius (*controvers.* 11, *Phys.*) and Vasquez (*1.* 2, *disp.* 25, *cap.* 3) — hold that nature is only an active principle. Others — among whom are Mastrius and Bellutus (*disp.* 6 *Phys.*, *q.* *prima*) — hold that nature is both an active and a passive principle. Still others — such as Scotus (*2 d.* 2, *q.* 10, § *Respondeo.* F., and *d.* 18, *q.* *un.*, § *Contrà primum*, and *4 d.* 43, *q.* 4, § *Intelligendum*), Faber (*Theor.* 33), and Pontius (*disp.* 36, *q.* 2, *n.* 9) — maintain that nature, properly taken, is only a passive principle. I see, however, that this dispute is almost entirely verbal and consists in the multiple acceptance of the terms *nature* and *natural*. Some take these more broadly, others more narrowly — just as was said of *praxis* in (*Log.* l. 1, *q.* 2, *art.* 5, *dub.* 1)

and of *action* in the work on generation (*l. 3, q. 1, art. 1*). Therefore, to satisfy the proposed difficulty, I premise what I observed in the preceding article.

Note first from Scotus (*q. 1 prol., § Ad quest. L.*) that the receptive subject of a certain form can be compared in two ways — either to the form it receives, or to the agent from which it receives it. If it regards the form, either it inclines toward it — as fire toward an upward place — and is called *natural*; or it does not incline toward it but resists, as fire toward a downward place, and is called *violent*; or it neither inclines nor resists, as the surface of a wall toward receiving whiteness, and is called *neutral*. But if it is referred to the agent, either the agent habitually produces that form — and this kind of form is called *natural* — or the agent does not habitually produce it and does produce it, and it is named *supernatural*, as if God were to produce fire immediately, that fire would be called supernatural. Likewise, if He were to restore sight to a blind man, it would be a miracle, as Christ foretold (*John 9*): *A saeculo non est auditum, ut quis aperuerit oculos caeci nati* — from the beginning of the world it has not been heard that anyone opened the eyes of one born blind.

Note second from the same Doctor (*4 d. 42, q. 4, § Intelligendum. A.*) that *natural* is an equivocal name which must be distinguished and explained with respect to its multiple acceptances (*1 Top., c. 12*). Natural is taken, first, as opposed to supernatural — in which sense everything contained in the series of created things is called natural, and God alone is called a supernatural being, because He exists above all created things, surpassing and excelling them as their cause and author. Second, as opposed to free — in which sense every necessary agent lacking will and freedom, or everything non-free, is called natural. Thus fire is a natural agent and naturally heats and burns, and man naturally reasons, laughs, and performs other actions naturally, insofar as he is endowed with intellect and other necessary and natural potencies, distinct from the will, which is a free potency. Third, as opposed to the violent and the neutral — in which sense, natural is that which inclines toward receiving a certain form. Hence Augustine (*3 de lib. arbit., cap. 1*) writes that the downward motion of a stone is natural, since by its own nature it tends toward that place — and it is in this most proper sense that nature, from which natural is derived, is defined in *2 Phys., T. 3* as the intrinsic and *per se* principle of moving and resting.

Assertion. Nature taken most strictly and narrowly is only a passive principle, according to Aristotle, Scotus, and truth. This assertion is divided into three parts.

The first part is established first from Aristotle (*cited, cap. 3, T. 5, proximé cit.*), who, when showing us what kind of principle nature is — active or passive — offers the example of fire, which is naturally carried upward, evidently with respect to a passive principle, as the word *is carried* plainly indicates. And shortly before (*T. 3, cap. 1*) he had given the analogy of a sick physician who is cured, not insofar as he is a physician — for it is accidental that the patient is a physician —

because he is not cured insofar as he has an active principle, that is, medical art, but insofar as he has a passive principle of receiving health. The same is suggested in (8 *Phys.*, T. 27, 28, 29) and (2 *Phys.*, T. 71 and 3 of the same work, S.), where he says that physically moved movers are the subject of physical consideration, but not unmoved movers. And this, according to the Greek codex, Aristotle had plainly indicated in the definition of nature (2 *Phys.*, T. 3) — which, as the Conimbricenses note (*ibid.*, in cap. 1, q. 2), reads: nature is the principle and cause in that which is moved. Where the verb *is moved* — a passive form — is used.

The second part is shown from Scotus, who writes (2 d. 2, q. 10, § *Respondeo, sub F.*): motion is not natural because it has an active principle, but because it has only a passive principle, naturally inclining toward motion. He teaches the same expressly (d. 18, q. un., § *Contrà.* 4., and in *Rep.*, d. 17, q. 3).

Mastrius and his colleague (*cited above*) respond that those testimonies of Scotus are to be understood primarily of the passive principle and secondarily of the active, insofar as the active is connected to the passive. On the contrary: the Doctor (*cited*) explicitly says that only the passive principle is the nature described in 2 *Phys.*, cap. 1. Therefore, since the particle *only* is exclusive, it undoubtedly excludes the active principle. I add that in (5 *Met.*, in exp., cap. 4) he evidently removes the response given, in these words: the principle of motion which is called nature — by which natural motion is distinguished from violent — is not taken for the active principle, as some say, but for the passive principle. And the same (7 *Met.*, q. 12, § *Ad 1.*) adds: motion is never called natural because of an intrinsic active principle, but only because of a passive one.

Nor does it help to say with Mastrius that Scotus (q. 1 *prol.*, § *Ad argumenta pro opinione Aristot. Q.*) extends the definition of nature given in 2 *Phys.*, T. 3 to the active principle. For the Doctor there says that many subjects are naturally receptive of a certain perfection that do not have an intrinsic active principle — as the organic body is indeed receptive of the soul, yet not its efficient principle. Likewise, the soul is receptive of grace and glory, but not their efficient cause. Furthermore, in (5 *Met.*, near the end, comm., cap. 4) he adds that it is not incompatible for form, as it is nature, to have an active principle. Therefore it seems that the Doctor comprehends under nature both principles — the active as well as the passive.

However, the Doctor there teaches that in the class of created things, certain things have the capacity to receive a certain perfection, yet do not have in themselves an active power to produce it. But whether nature most properly taken is an active or passive or both principles simultaneously, he does not decide in that passage — as he does in the passages cited. Moreover, although something may in itself possess a natural active principle of producing something — as a heavy thing has the active principle of tending downward and a light thing of tending upward — nonetheless it is not called nature in the strict

sense because of that active principle, but because of the passive principle. For it is accidental that a thing has an active principle, as I made clear above in the case of the sick physician. Thus also the testimony adduced from (5 Met.) is satisfied: form is properly called nature not because of an active principle but because of a passive one. All the more so since no one denies that Scotus opines rather than demonstrates — and perhaps for this reason he places the word *repugnare* (*is incompatible with*) there with some tentativeness, even though he himself firmly and evidently adheres to the opinion he cites.

The third part is proven first from Scotus (5 Met., *now cited*). A change is natural with respect to which the patient is changed — that is, in the way it is naturally suited to be changed by any agent — as is evident from (8 Phys., T. 32), where it reads that light things are carried upward and heavy things downward because they are naturally suited to be moved in this way. But the patient is never naturally suited to be moved in this way because of an active principle existing in it, but only because of a passive principle — so that if water is heated by fire, that heating is not natural to the water not because it is produced by fire, but because the water does not naturally incline toward it. Whereas if the same water becomes cold, that cooling is natural not because it is produced by the water itself or by another agent, but because the water by its own nature inclines toward it.

Second, from the same Doctor (4 d. 43, q. 4, § *Intelligendum. D.*): that is *per se* the cause of some effect which, once posited — with everything else excluded or changed — the effect follows. But once the natural inclination of the subject toward receiving something is posited, even if there is in the subject no active principle for producing it, the effect properly follows and is properly called natural — and not the reverse. Thus health is called natural to man not because he has in himself an active principle for it — which is accidental (2 Phys., T. 3) — but because by his own nature he inclines toward it. Therefore properly speaking nature is a passive principle. I add that it is impossible for the active principle of motion to be in the moved thing primarily and *per se* — since it is accidental for the mover and the moved to coincide in the same subject, since they can be separated from one another. Say, therefore, that nature properly taken is only a passive principle.

First Objection against the first part of the assertion. Form is nature (2 Phys., T. 11). But form is an active principle. For in the passage now cited, (T. 70 and T. 13), if a bed is buried and rots and then sprouts, it will sprout not as a bed but as wood. Again, in the chapter on the parts of animals, (*cap. 1*), the soul — which is form — is nature, and Aristotle there wants it to be an active principle.

Furthermore, in (9 Met., T. 13): nature is of the same genus as active potency. Moreover, in (8 Phys., T. 27): animals are naturally moved of themselves because they have within themselves an active principle of moving, which is the soul,

and the soul is nature. Therefore in Aristotle's school nature is predicated of an active principle.

I concede the major and distinguish the minor: as it is nature, I deny — for thus it is a passive principle, from Scotus (*5 Met., in comm., cap. 4, 7 Met., q. 12, q. Ad omnes.*). As it is distinguished from art and from a free principle, I concede — as Scotus writes (*q. 1 prol., § Ad argumenta pro opinione Aristot. Q.*). By this distinction all the cited testimonies of Aristotle are explained, and I declared this above in Note II.

Second Objection. Natural things differ from artificial things in that artificial things do not have an active principle, whereas natural things do (*2 Phys., cap. 1, T. 3*). But if nature were a passive principle, there would be no such distinction, since both natural and artificial things would share in a passive principle.

Confirmation I: from (*6 Met., l. 1*), the principle of artificial things is in the knowing agent, and the principle of natural things is in the moved thing. But the principle of artificial things that exists in the knowing agent is active. Therefore the principle of natural things is likewise active. Confirmation II: in the definition of nature the word *cause* is placed. But a cause is active, since it influences the effect. Therefore nature is an active principle.

I respond with Scotus (*2 d. 18, q. un., § Contrà. C., and 6 Met., in com., cap. 1, in fine, and Met., q. 2, § Ad aliud de differentia*): natural and artificial things are distinguished in that natural things have a passive principle inclining toward the perfection they receive, while artificial things have a neutral and indifferent principle for receiving this or that form — as wood is indifferent toward the craftsman fashioning from it the form of Jove or Mercury. To Confirmation I: I say that *principle* is not taken uniformly but differently — in the craftsman it is active, in the natural thing it is passive, as the Doctor teaches (*cited above, before D.*). To Confirmation II: I say that *cause* is used in the definition of nature for a passive and receptive cause having an inclination toward the form to be received — as is evident in matter, which is numbered among the causes even though it is passive.

Third Objection. From (*3 Eth., l. 1*): the violent is that whose principle is outside, with the patient contributing no force. Therefore by opposition, the natural is that whose principle is within, having some force or power of acting — and accordingly, nature is an active principle.

I respond with the Doctor (*in Met. recently cited, at the end of q. 12, and 4 d. 29, q. un., § De primo. B.*) that the words of the Philosopher, *with the patient contributing no force*, are to be taken not negatively but contrarily. That is to say: the violent is that whose principle is outside, with the patient resisting and reluctant toward the form being received in it, toward the contrary of which it inclines. The natural, by contrast, is that whose principle is within, inclining toward receiving the form.

Fourth Objection, against the third part. Natural is named from nature, from which it derives. But by an active principle something is called natural — as igniting is natural to fire, and ignition is a natural action proceeding from fire acting actively, as Augustine (*in Ps. 104*) and Damascene (*4 fidei, c. 41*) indicate. Therefore nature is an active principle.

This argument is given great weight by Mastrius (*cited*), but it seems to me to be of little moment and weak force. For it commits the sophism of equivocation, placed in the multiple acceptance of the word *natural* — of which I made mention above, as Scotus notes (*7 Met., q. 12, near the end, and he suggests the same in q. 1 prol., q.*). For it holds of nature and natural as opposed to free and spontaneously acting — but not of nature and natural as in (*2 Phys., T. 3*), as opposed to the violent and the neutral.

Article III. To What Things the Account of Nature Belongs

A question can arise regarding matter, form, the composite, and the soul — especially the rational soul — which will be briefly decided and settled through the following assertions.

First Assertion. Matter is nature. This is taught against Vallesius (*contr. 11*) and Vasquez (*1 l. 2, disp. 25, n. 22*) by the natural philosophers together with Aristotle (*2 Phys., T. 4 and 10, and 5 Met., T. 5*) and Scotus (*ibid., in com., and 2 d. 18, q. un., § Contrà, sub C.*). It is proven first by the reasoning touched upon by Aristotle (*cited*): what constitutes the natural composite is nature, because the natural does not come to be from non-nature. But matter partially constitutes the natural composite — for what is composed of matter and form, from what was established in the preceding book (*q. 6, art. 1*). Therefore matter is nature.

Second, that to which the definition of nature belongs is nature, as is evident by the argument from definition to the thing defined. But the definition of nature applies to matter — for it is the first subject of every natural transmutation and the first principle of any natural motion. Therefore matter is nature.

Second Assertion. Form is nature, both of non-living and of living things, including the rational soul. This assertion is threefold. The first part is transmitted by Aristotle and Scotus in the preceding assertion, and is established first: what is denominated by an intrinsic denomination is intrinsically such — as is evident of a man who is intrinsically called rational, and of a white wall which is called white. But form is denominated nature (*2 Phys., T. 11*). Therefore it is truly nature.

Second: what is more such in a given order is such in that order — as what is more white. But form is more nature than matter (*2 Phys., T. 12*), and matter is nature as established above. Therefore form is also. Third, the whole comes to be from natures (*ibid.*), among which form is the principal. And (*ibid., T. 14*): generation is the way toward nature, or toward form — which is rightly called

more nature, both because it is more perfect than matter and because it is a principle in a more perfect mode. Therefore the account of nature is well adapted to form.

The second part is defended by Aristotle (*cited, T. 1, 12, and 1 de anima, T. 1, and 1 de partibus animalium, cap. 1*), Scotus (*Quol. 9, art. 2 and 3*), and the other philosophers, against Albertus (*2 Phys., Tract. 1, cap. 1*) and Simplicius (*in the present passage*). It is proven first: the soul of living things endowed with vegetative and sensitive life is the true form of the organic body. But from the first part of this assertion it has been shown that form taken universally is nature. Therefore the soul, whether vegetative or sensitive, is nature.

Second, the soul taken generally is the principle and cause of motion and rest. Therefore it is nature. The consequence holds. The antecedent is shown: the soul is the receptive principle and cause of natural changes suitable to it — such as nutrition, growth, sensation, and the like — which proceed from nature. Therefore the soul is not to be exempted from the account of nature.

The third part is intimated by Aristotle (*2 Phys., T. 12*), who numbers man among the things constituted by nature. But man is most of all man through the rational soul, which is his form and principal part. And in (*1 de anima, T. 1*) he calls the soul taken universally a nature — and under the soul, as under its quasi-genus, the rational soul is comprehended. And in (*2 of the same work, T. 24*): the soul is the first principle of vegetating and understanding — and the rational soul is this kind of principle, especially of understanding, by which it is distinguished from others. This is stated plainly by the Doctor (*cited, and 2 d. 18, q. un., sub C., § Contrà, and 4 d. 43, q. 2, art. 1, and elsewhere*).

It is proven first: every form informing, together with matter, constitutes a physical whole, is nature (*1 Phys., T. 12*). But the rational soul is an informing form — both because it is defined in the Council of the Lateran under Leo X and of Vienne under Clement V, and because it constitutes man in the being of man and distinguishes him from others. Therefore it is nature.

Second, the definition of nature applies to the rational soul — for it is the first principle and cause of natural changes and operations, namely vegetating, sensing, and understanding, not insofar as these proceed from it actively, but insofar as they are received in it passively. Therefore it is nature. Furthermore, in (*1 l. 1 de anima, q. 1, art. 2*) I shall show that the rational soul, with respect to the grade of reasoning and understanding, belongs to the natural philosopher, since it is the true and proper form of the human body, through which man is integrated.

Third Assertion. The form of the whole and the composite is not nature. From this Fuentes (*2 Phys., q. 1, dif. 2, art. 8*) and Mastrius (*disp. 6, q. 2, art. 1*) deviate. But all other philosophers incline toward this view, together with Aristotle (*2 Phys., T. 12, and 5 Met., T. 5, cap. 4*) and Scotus (*ibid., in com.*). Hence Mastrius (*cited*) is

refuted — who admits that this is Aristotle's view but denies it is Scotus's. For Scotus clearly teaches and defends it in the passage cited, saying with Aristotle that where Aristotle speaks of form in that place, it is to be understood of the form of the part, not of the form of the whole. Therefore when Scotus calls the form of the whole the essence and quiddity of the thing, he is taking nature in the passages cited by Mastrius in a broad sense — as he himself declares in explaining the modes of nature in his commentary on that same passage of the *Metaphysics*.

The assertion is established first: what comes to be from something is not that from which it comes to be — as in natural things a son, who comes to be from a father, is not the father; and in artificial things an ark, which comes to be from wood, is not wood. But the form of the whole and the whole itself consist of natures — namely matter and form, which are natures as proven above. Therefore it is not nature.

Second, nature is the first principle of motion and rest (*2 Phys.*, *T. 3*). But the form of the whole and the composite is not the first principle, but rather something derived from first principles. Therefore it is not the nature defined in the passage just cited. Furthermore, Aristotle (*2 anima*, *T. 4*) proves that the soul is not a body because it is in the body. And Augustine intimates the same (*lib. de immortalitate animae*, *cap. 7*, and *lib. 83*, *qq.*, *q. 54*). But in the composite, nature is like a part in the whole. Therefore the whole is not nature but a thing having nature.

First Objection, against the First Assertion. Aristotle (*5 Met.*, *cap. 4*, *T. 1*) says that matter is nature only metaphorically, and gives the reason: because every substance is called nature on account of form. Confirmation I: nature, beyond the passive principle, denotes an inclination toward what is to be received in it. But matter of itself is indifferent and indeterminate toward any form whatever, as Scotus teaches (*4 d. 43*, *q. 3*, *1.*). Therefore it is not nature. Especially because, according to Aristotle (*2 Phys.*, *T. 5*, and *8 of the same work*, *T. 32*), natural motion is determinate — as the motion of the elements. Therefore if matter were nature, all motion would be natural, since it inclines toward all, and no motion would be violent, since matter cannot suffer violence.

Confirmation II: nature is the receptive principle of motion. But matter is not the subject of motion — rather the composite is, which according to Scotus is established as the subject of all accidents. Therefore matter ought not to be regarded as nature.

The Doctor responds in his exposition of that text of Aristotle: Aristotle says extensively and improperly that every substance is nature, because nature is substance. Yet shortly before he had already affirmed that matter is properly nature — and he had premised this in (*2 Phys.*, *T. 4 and 10*). Therefore there he only intimates that form is a more excellent and nobler nature, confirming what

he had already said in (*Phys., cited, T. 12*): form is more nature than matter. To Confirmation I, I concede the major. To the minor, I say that matter participates in a universal and unlimited inclination of itself toward every form, which inclination is limited and determined by this or that form. Thus the matter of a stone, because of its form and gravity, inclines toward downward motion, as the Doctor clearly explains (*in both works, 2 d. 18, q. un.*). Hence the same Doctor (*in Met., cited, with Aristotle, ibid.*) teaches that matter is nature because it is receptive of form, and that every mode of nature is reduced to form, which is the principal nature. To Confirmation II, I concede the major and distinguish the minor: matter is not the *quod* subject of motion, I concede; it is not the *quo* subject, I deny — especially because it is the common subject of every generation and corruption, as is evident (*1 de generatione, T. 1*).

Second Objection, against the first part of the Second Assertion. Form is the active principle of natural operations, as no one denies. But nature, from the assertions above, is a passive principle. Therefore form is not nature.

The Doctor responds in the places recently cited: form is called nature not with respect to the active principle but with respect to the passive. Thus the downward motion of a heavy thing is called natural not insofar as the mobile moves, but insofar as it is moved by an intrinsic principle, which is passive.

Third Objection, against the second part of the said Assertion. The definition of nature does not belong to the soul. Therefore the soul is not nature. The antecedent is shown: for the soul is defined as the first act of the organic body having the potency for life (*2 anima, T. 6*).

I respond that the soul is considered in two ways. One way as it is nature — thus the definition of nature applies to it, since it is the first principle and cause of natural motion, namely vegetating, sensing, and understanding, not indeed insofar as these proceed from it actively, but insofar as they are received in it passively. The other way as it constitutes the living body, giving it life and animated being — and thus it is defined in the passage cited from *2 de anima*. Nor is it inconvenient that the same thing should have diverse definitions, as is evident in logic regarding genus, difference, and others. For with respect to diverse formal accounts, those diverse definitions are sought.

Fourth Objection, against the third part of the same Assertion. Nature is established as the principle of physical motion, which is material and corporeal. But the rational soul, with respect to the intellectual grade, does not depend on matter or body in being or in operation — for the will and intellect and the operations of each are altogether immaterial and spiritual. Therefore the rational soul according to the said grade is not nature.

I respond that nature need not be the immediate subject of motion, as is evident from matter, which — although it is nature — nonetheless does not receive alterations, augmentations, and other motions immediately, but rather the

living and animated composite does. And the same must be said of the vegetative and sensitive soul, which do not immediately receive the aforesaid motions. Therefore it suffices that a thing be an essential part of the physical composite for it to be nature. Now since the rational soul, even according to the said intellective grade, is this kind of physical form of the human body, it therefore rightly possesses the account of nature, as the Doctor indicates (*Quol. 9, § De secundo, before D.*).

Fifth Objection, against the Third Assertion. In (*2 Phys., l. 1*) these words are found: *naturalia sunt quidem, ut animalia et partes ipsorum et plantae et simplicia corpora, ut terra, ignis*, etc. — things that are natural include animals and their parts, plants, and simple bodies such as earth, fire, and so on. The same is found in (*5 Met., cap. 4, T. 5*): *Natura quidem igitur, quod ex his utrisque est, ut animalia et eorum partes* — nature, then, is what consists of both of these, as animals and their parts. But animals and the other things named are composites having the form of the whole. Therefore the form of the whole and the whole are nature.

Scotus answers in his commentary on that text of the *Metaphysics*: by *nature* there one must understand things having nature — as Aristotle also explains (*2 Phys., T. 5*) — meaning that composites are not nature but things having nature.

One may ask first whether privation is nature. I respond that it is nature in a qualified sense, but not simply, as Aristotle (*cited, T. 15*) acknowledges. The reason is that privation is in some way form, since it is in a subject as form is in matter.

One may ask second whether matter and form are univocally predicated under the common account of nature. I respond affirmatively with the Doctor (*2 Rep., d. 17, q. 3*). The reason is that the definition of nature applies equally to each. And those things that share the same definition are univocated with one another.

Question II. On Art

Art is defined by Aristotle (*6 Eth., 4*) and Scotus (*Quol. 8, § Ad ista. E., and 1 d. 38, q. un., F.*) as a habit productive with right reason. Its parts have been explained and its acceptances have been adduced in the *Logic* (*lib. 1, q. 2, art. 1*). Here we treat of art only insofar as the essence of nature may become better known to us and its similarity or dissimilarity may be brought to light.

Article I. Whether Art Imitates Nature

No one doubts that art imitates nature, since the statement (*2 Phys., T. 22*) is well established. Yet in what respect its truth holds may be questioned — namely whether it is in the effects, in the agent, or in the form of each.

Assertion. Art in some things imitates nature, and in some things departs from it. This assertion has two parts and is intimated by the Doctor (*2 d. 18, q. un., § Contrà C.*). The first part is established first: just as nature assimilates to itself the

effect it produces — and this is held to be its most perfect work, in accordance with the well-known saying, *the most natural work is to generate what is similar to oneself* — so art renders the work it produces similar to the form or idea the craftsman carries in his mind. Toward this Aristotle (*7 Met.*, T. 22, and 12 of the same, T. 24) looks when he says that health and a house externally are produced from health and the house that is within, or in the mind of the craftsman.

Second, each presupposes a subject from which it produces its effects, since neither can operate from nothing, as the Doctor shows (*4 d. 1, q. 1*).

Third, each advances from the imperfect to the perfect, as daily experience confirms, and as Aristotle observes (*2 de generatione animalium*, cap. 3, and *2 de historia eorum*).

Fourth, both are the measure of the things to be done by them — for they operate by certain rules and laws, as is evident from the art of dancing, singing, and the like.

Fifth, in both there occur accidents and monsters, of which we treat in the following Book IV.

The second part is shown first: nature is a substance (*2 Phys.*, T. 4), while art is an accident residing in the category of quality. Second, nature is an internal principle of motion and rest, while art is only an external and directive one, as Scotus warns (*1 d. 38, q. un.*, § *Ad autoritates. F.*). Third, nature is the maker of true and proper things, while art only of likenesses and appearances. Hence natural forms are alive and active, while artificial forms are, as it were, dead, having no power of acting. Fourth, nature is occupied with hidden and recondite elaborations, while art is engaged with external and visible ones. Fifth, nature is perfectible by art, and art is its perfective. Hence arises that adage (*2 Phys.*, T. 79): art perfects nature — as from rough stone a beautiful statue is fashioned, and from the mixing of colors things more beautiful than nature has made are produced. Art also teaches how to operate perfectly what is done imperfectly by the guidance of nature alone, as is evident in music.

Furthermore, what cannot be effected by nature is elaborated by art, as a house. Moreover, what by its nature appears immovable is moved by art, as a clock. And finally, what the force of nature does not attain is wonderfully accomplished by art, as is evident from cannons and other artifacts sufficiently admirable, which reduce men to stupefaction.

Objection. Nature properly taken is only a passive principle. Therefore it is not the cause of real effects, and accordingly does not differ from art.

I say that in the present context nature is taken not only as opposed to the violent, but also as distinguished from a free agent, as the Doctor notes (*5 Met.*, in com., cap. 4).

Article II. Whether Art Can Produce the Works of Nature

The earlier opinion is that of Albertus (*3 Miner., cap. 9*) and Henry (*Quol. 5, q. 3*), who affirm that art can bring about the works of nature. The later opinion is that of Scotus (*Theor. 18, and 2 d. 18, q. un., § Dico, sub K., and 4 d. 3, q. 3, in solutione 3. H.*), Thomas (*2 l. 2, q. 77, art., ad 1*), and the disciples of both — who deny that art *per se* and by its own proper power can accomplish the works of nature.

Note that art is taken in two ways: one way, for practical knowledge that directs what is to be made — in this sense art is one of the five habits of the intellect enumerated in (*6 Eth., 3*). Another way, for the form of art in matter elaborated by the craftsman — as the image of Saint Francis formed on a wall.

Furthermore, in a work of art two things can be seen, as in a chest: the wood, which is from nature, and the mode or figure, which is from art. Furthermore, a work can be done by art in two ways: *per se* and by proper power, or *per accidens* and by the application of actives to passives.

Assertion. Art by its own power cannot attain the effects of nature. So the Doctor (*ubi supra*). It is proven first from Aristotle (*2 Phys., T. 2*), who, in establishing the difference between art and nature, writes that nature has in itself the principle of motion and rest, while art lacks this kind of principle. Second, every true and proper cause contains virtually the effect to be produced from it — otherwise it could not produce it. But art does not virtually contain the effects of nature, because these are substances while art is an accident, and I shall show elsewhere that an accident cannot produce a substance. Third, art does not operate except by directing, regulating, and modifying the works of nature, as I declared in the preceding note. But direction, regulation, and modification — being intentional accidents — cannot attain the offspring and effects of nature. Therefore art by its proper power cannot produce them.

First Objection. In (*Exod. 7*), by magic art the wise men of the Egyptians made serpents, which Augustine — in numerous places, notably (*10 Civit., cap. 8, and lib. 2, qq. super Exod., q. 21*) — testifies were true serpents just like the serpent made by Moses. Again, Vives (*in com., 4 Civit., cap. 19*) narrates from Livy and Plutarch that a statue of Fortune spoke twice, in these words: *Rite me matrona vidistis, riteque dedicastis* — Rightly, matrons, did you see me and rightly dedicate me. Many other marvelous things fabricated by art are reported by historians, which appear to have attained the works of nature.

I respond that these and similar things adduced by the adversaries are to be interpreted through the distinction given in the preceding note — namely that they are effected by art not *per se* and by its proper power, but *per accidens* and by the application of actives to passives, as Scotus acknowledges (*2 d. 18, q. un., before § Ad argumenta. L.*).

Second Objection. By a certain art there are produced certain effects that nature cannot attain. Therefore much more can art produce effects that nature makes. The consequence is evident by the argument from the greater to the lesser. The

antecedent is established regarding icons and astronomical rings, by the power of which many things are accomplished that surpass the forces of nature.

I deny the antecedent. In response to its proof, I say that those works are accomplished not by the power of such images and figures, but with the help of demons, who come — by explicit or tacit compact — to mock and deceive men and to draw them away from the worship of the true God. Hence Augustine (*lib. 2 ad Simplicianum*, q. 3), from (1 Reg. 28), believes it possible by God's permission that a demon through the witch of Endor caused Samuel to rise up to speak with Saul.

Third Objection. By art are made glass, butter, and things of that kind, which are substantial effects. Therefore the effects of nature can be produced by art.

I concede the antecedent and deny the consequence, because effects of this kind do not proceed from the power of art but from the power of natural things applied through appropriate positioning, mixing, and application of actives to passives, as the Doctor indicates (4 d. 3, q. 3, § *Ad 1. G. and H.*), and before him Augustine (3 *Trin.*, 8), who says: the man who plants does not create the harvest, nor did Jacob, applying rods at the watering troughs from which the sheep drank, create the spotted color of the sheep.

Article III. Whether Artificial Forms Are Distinguished from Natural Ones

The Parisienses (2 *Phys.*, q. 4) report that the Nominalists hold that artificial forms are confused with natural ones and that there is no distinction between them except with respect to words and names. Others, however, whom the said Parisienses and Antonio Andrea follow (*in cap. 1, lib. Sex Principiorum*), establish a real distinction between the aforesaid forms.

First Assertion. An artificial form is something real and positive. So the Doctor (8 *Met.*, *in com.*, cap. 3, and 4 d. 1, q. 1, § *Tertia ratio. K.*), and elsewhere as cited by Lychetus (2 d. 5, q. 1, § *Dicitur ab Henrico, in comm., before the solution of certain doubts*), whom Porretanus preceded (*lib. Sex Principiorum*, cap. 1). It is proven first from Aristotle (2 *Phys.*, T. 11), who says that a bed not yet having the form of art is only potentially artificial, but becomes actually artificial through the artificial form newly coming to it. Second, what falls under the object of sense is a real positive thing, since sense is of singulars (2 *Post.*, T. 27, cap. 11), which are real and positive — being things that are produced and perceived *per se*. But the form of art falls under the object of sense — for figure is a common sensible (2 *anima*, T. 64). Therefore the form of art is a real positive being.

Third, the term of a real positive action is real and positive, since action is not directed toward nothing. But the artificial form is the term of the real positive action of the craftsman — since the craftsman truly acts upon the pre-existing matter so as to introduce into it the form of art he intends. Fourth, art is defined

as a habit productive with right reason (6 *Eth.*, 4). Therefore its work is something real and positive, which cannot be without a real positive form — which is the artificial form.

Second Assertion. The form of art is really distinguished from the form of nature. This is derived from Aristotle (2 *Phys.*, T. 3 and 11) and Scotus (6 *Met.*, in com., cap., in fine, and 7 of the same, q. 12, § *Ad aliud*, and 2 d. 18, q. un., § *Contrà*, sub C.). It can be established first by the differences between each adduced in the second part of the assertion in Article I. Second, what remains when another is destroyed is really distinguished from it — as the Doctor subtly and effectively proves from Aristotle (2 d. 1, q. 4, § *Contra istam*). But the natural form remains while the artificial form perishes, as is evident from a statue figured in marble, which is destroyed in the marble while the form of the marble remains as it was before the impression of the said figure. Therefore the one really differs from the other.

Third, between accident and substance there is a real distinction, as is evident (7 *Met.*, sum. 1, cap. 2). But art is an accident, and its form is an accident — since it can be present and absent without the corruption of the subject. But nature and its form is a substance (2 *Phys.*, T. 4). Therefore between the said forms there is interposed a real distinction.

Third Assertion. An artificial form is not a location. This is drawn from the Doctor (*cited*) against Arriaga (*disp.* 6, sect. 2). It is proven first: if the form of art were a location, then when an artifact is merely changed locally, its form would also change — since its location changes. But this is plainly false, since the same artificial vessel, moved many times according to place, retains the same artificial form. Therefore, etc.

Second, the artificial form is effected by the craftsman, just as a natural form is effected by a natural agent. But the craftsman does not produce a location but presupposes it — for what is located presupposes the place in which it exists. All the more so since the same wood remaining in one and the same place receives several artificial forms — such as the form of Jove, Mercury, and so forth. Therefore it is evidently established that the artificial form is not a location.

Fourth Assertion. The artificial form is a quality that terminates quantity, elaborated by the craftsman through his practical intellect and will. From this the Doctor does not appear to deviate (*in com.* 12 *Met.*, T. 15, and 4 d. 1, q. 1, § *Tertia ratio*), which is maintained by John of Magistris (2 *Phys.*, q. 2) and the Parisienses (*ibid.*, q. 4), with whom Bonetus also agrees (*lib. de qualitate*, digress. ult.). It is explained before being proven. *Quality* is placed as the genus. *Terminative of quantity* is added to distinguish it both from the substantial form — which is the term of matter — and from the form or figure of quantity — which belongs to its own genus, as a triangle. The remaining parts are added so that its nature may be better known and its difference from other things may be

observed — especially from the intellectual form which is in the mind of the craftsman, in whose likeness the said form is produced, and on account of which it is called the external form, as Aristotle intimates (*7 Met., T. 22*): the house externally comes to be from the house within, or from the exemplar and form that the craftsman has in his mind. With the assertion and definition of the artificial form thus explained, it is easy to prove by the common and ordinary medium. For that is a good definition which partakes of genus and difference — and the definition given is of this kind. For its genus is quality, and the remaining words hold the place of its difference. And nothing deficient or superfluous is annexed to it, as a good definition requires — and thus it is correctly given.

First Objection, against the First Assertion. Many artificial forms come to be by subtraction of matter, as is evident from images and figures sculpted in marble. But what emerges by subtraction presents nothing positive — since rather a pre-existing positive thing is taken away than a new subsequent one should arise. Therefore artificial forms are not real positive beings.

I concede the major and distinguish the minor: with respect to the first term, I concede; with respect to the second term, I deny. This is evident from corruption, which is a privative and depriving motion that is followed by generation — which is a positive and acquisitive motion. Thus by the mere subtraction of parts of a natural subject, nothing positive is produced. Yet from that precise cutting, incision, and subtraction there arises an artificial form, which is indeed something positive.

Second Objection, against the Second Assertion. What possesses the same properties as something else does not differ from it, because the identity of properties argues the identity of nature. But the artificial form possesses the same properties as the natural form — for it is light or heavy, hot or cold, moist or dry. Therefore there is no distinction between the aforesaid forms.

I concede the major and distinguish the minor: *per se*, I deny; *per accidens*, I concede — that is, by reason of the natural subject, which truly participates in said properties. Just as if a heavy thing were tied to a large light thing and were carried upward, that upward motion would be attributed not to the heavy thing but to the light thing.

Third Objection, against the Fourth Assertion. Scotus (*4 d. 12, q. 4, § Ad quest. F.*) writes that figure — which is an artificial form — is a certain relation supervening upon diverse parts of quantity, which can be changed while the same parts remain in themselves and in the whole. Therefore the form of art is not a quality, which is an absolute being.

It can be responded that figure and any other artificial form presupposes and assumes the aforesaid relation of positions of the parts of quantity. But from these there arises and follows the form of art impressed upon them and upon

the whole composed of them — which is an absolute entity placed in the category of quality. Thus the image of a sculpture presupposes the incision of parts, from which subsequently emerges the image called a statue. It can also be conceded with probability that the form of art is formally the said relation — as the Doctor (*cited*) seems to hold — and that it is denominatively quality, as I indicated in the *Logic* (*q. de qualitate, ad finem, art. 2*).

Article IV. Whether True Gold Can Be Made by Alchemy

Blessed Angelo de Clavasio in his *Summa* (*verb. Alchymia*), following Averroes and others cited by the recent authors, holds that the production of true gold by alchemy is impossible. Oldrardus, however, in his *Consilia*, and not a few others following Albert (*3 Miner., cap. 8*) and Thomas (*2 l. 2, q. 77, art. 2*), hold that alchemical art can attain the production of true gold.

Note that in things that are very arduous and difficult, or that men most greatly desire — such as gold and silver — in accordance with that saying of Virgil (*3 Aen.*): *Quid non mortalia pectora cogis, / auri sacra fames* — to what do you not drive mortal hearts, O accursed hunger for gold — and Ovid (*1 Met.*): *Effodiuntur opes irritamenta malorum. / Iamque nocens ferrum, ferroque nocentius auro / Prodierat* — the wealth that provokes evil is dug up, and now harmful iron and gold more harmful than iron had appeared — there is danger that the demon may intrude, who knows best how to apply natural actives to passives and nearly all sublunary things obey his will, as Scotus notes (*2 d. 18, q. un., § Dico igitur. L.*). For this reason the Church, as a provident mother — lest the faithful of Christ perish through this kind of production — reprobates and condemns the said alchemical art in the extravagance *Spondet*, and declares that those selling alchemical gold are bound to restitution. The reason is that for the most part alchemists do not master this art well, and of them may be said what (*2 Tim. 3*) says: *Semper addiscentes et nunquam ad veritatis scientiam pervenientes* — always learning and never arriving at the knowledge of truth. Hence the adage on everyone's lips: alchemists do not fill but empty purses, do not make but consume gold.

Assertion. True gold and silver can be made by alchemical art, through the proper application of natural actives to passives. This is not at odds with the principles and foundations of the Doctor (*recently cited*). It is proven first: art imitates nature (*2 Phys., T. 22*). But nature from sulphur and mercury, through the intermediate heat of the sun, with the elements concurring, produces gold in the womb of the earth, as is written in (*the book on the properties of things, c. de Alchymia*). Therefore art, from those same principles and causes, by the heat of fire — which is of the same kind as the heat of the sun — can likewise elaborate and make true gold.

Second, the raw can be cooked and the impure purified (*4 Meteor., sum. 1, cap. 2 and 3, and sum. 2, cap. 3 and following*). But lead and tin are raw, and copper and

iron are impure. Therefore, with the appropriate requisites applied, through various concoctments and purifications, they can be rendered cooked and pure — such as gold and silver.

Third, more outstanding and excellent works are produced by the benefit of art than the making of gold and silver. Therefore if art attains those, it also attains this — for what can do the greater can certainly do the lesser. The antecedent is shown: by art, bees are generated from a slaughtered young bull, as Scotus (*ubi supra*) testifies, following Augustine (*2 de gen. contra Manich., cap. 17*). From a basilisk and from women's hair, scorpions and other things are born, as Pliny reports (*lib. 11, cap. 20*). These surpass the production of gold and silver, which are inanimate — and the inanimate is surpassed in nobility by the animate, as Augustine teaches (*lib. de vera religione, cap. 55, ad finem, and cap. 37*). I add that by the power of certain herbs, glass, and by human art, gunpowder, the cannon, and similar things are fabricated — which seem not only to equal the production of gold and silver, but to surpass any other work and to be assimilated to the divine, as Paul Arelius elegantly follows through (*Tomo 2 suorum operum*). And that certain men have mastered this art well and have produced true gold and silver is reported by men worthy of trust and distinguished writers, to whom the greater part of modern authors assent.

First Objection. What is perfect in its genus does not have a vague and indifferent cause but a certain and determined one, as is evident from man, lion, and other things perfect in their species. But gold and silver are perfect in their genus, as Aristotle touches upon (*ubi supra*). Therefore, since gold is produced in the womb of the earth by the power of the sun, it cannot be generated in any other way, such as by alchemical art.

I respond that the major is not universally true. For the most perfect fire of the elements is generated from another fire, from solar rays, and from the collision of two bodies, as the Doctor indicates (*1 d. 2, q. 7, § Ad 1. S.*).

Second Objection. Long experience has established that alchemists have not yet produced true gold, even though they have labored greatly and consumed much in searching for and obtaining it. What has not yet been done does not seem any longer feasible or possible.

I respond that although, because of the excellence and difficulty of that work, many have not attained its production — since virtue and art are concerned with arduous and difficult things, as St. Bonaventure says (*3 d. 40, q. 3*) — it must nevertheless not be denied that it is unfeasible and impossible. For many things are feasible and possible that have not yet been done — such as the squaring of the circle, the Antichrist, and things of that kind. All the more so since truly certain men have accomplished it and have well understood the method of doing it — as Thomas (*cited at the beginning of this article*) and Cajetan (*ibid.*) attest.

Third Objection. Alchemical gold does not have the properties of true gold — for it does not strengthen the heart, nor is it ductile into very thin sheets. Therefore, if such is the gold, it is only counterfeit and adulterated gold, as it were generated from an illegitimate parent.

I respond that even if sometimes this kind of gold does not obtain the affections of true gold — perhaps because the agent does not know the proper method of producing it — it is nonetheless absolutely feasible with all its properties and affections, as the arguments I adduced above well establish.

Book IV. On Causes.

That philosophy arose from knowledge of effects and ignorance of causes is attested by Aristotle (*1 Met. cap. 2*). For causes are, as it were, perennial springs from which the streams of natural things flow. On this account Virgil, at the end of the second Georgic, cited by St. Augustine (*in Enchir. cap. 16*), sings: *Felix, qui potuit rerum cognoscere causas* — "Happy is he who has been able to know the causes of things." And a thing cannot be known unless its causes are known, as Scotus writes after Aristotle (*2 Met. T. 11*) in (*3 distinct. 22. §. Rationes, quas Paulo ante C*). For this reason causes must be treated.

Question I. On Causes Taken Generally.

Article I. What a Cause Is.

There is no doubt whether a cause exists, since when effects are evidently perceived, there must be a cause. But philosophers are not in agreement on what a cause is, although their dispute is of little moment and can be reduced to a good and legitimate sense, as will become entirely clear through what we now set forth in opposition.

Note that "cause" is taken in two ways. First, for everything from which something proceeds in any manner whatsoever: in this sense "cause" is confounded with "principle," a usage Aristotle mentions (*12 Met. T. 12. cap. 2*), calling privation a cause, when it is plainly evident that privation is only a principle in the process of becoming, without any influx into the effect. In this sense the Greek Fathers perhaps speak when they assert that in the Godhead the Father is the cause of the Son, and likewise that the Father and Son are the cause of the Holy Spirit, taking "cause" in the sense of "principle." Second, "cause" is taken for that which flows into another, or in consequence of whose being another distinct thing follows — distinct, that is, either in nature or in numerical or specific identity. In this sense the Latin Fathers are interpreted, when they deny that in the Godhead the Father is the cause of the Son, because although the Father generates the Son and communicates being to him, nevertheless the Son is not other than the Father, since he enjoys entirely the same nature.

The thesis is: a cause, properly speaking, is a principle that of itself flows into an effect. This is indicated by Aristotle (*4 Met. at the end of T. 3*) and the author of the book *On Causes*, with whom agrees Mayr (*Quol. 101. §. Circa 1. partem*). And it is expressly defended by Scotus (*5 Met. in com. T. 1. cap. 1*), who says: a cause is that which necessarily flows into the being of what is caused. He also touches on it (*in lib. de primo principio cap. 1*), as well as in (*Theor. 19*). It is explained before it is demonstrated. "Principle" is placed as the genus. "Of itself" is added to distinguish it from a per-accidens cause. "Flowing" is said on account of privation, which flows into nothing and is called a cause only popularly and not philosophically, as the Conimbricenses explain (*1 Phys. cap. 5. quaest. 1. artic. 1. in fine*). "Into an effect" is added so that the distinction between the divine Persons who are produced — who are not effects of the one producing them, since they share the same numerically identical essence — may be made known. The thesis, so explained, is easy to prove. For it consists of genus and differentia, explicitly declares the nature of a cause, contains nothing superfluous, and is not accommodated to another thing: therefore it is a correct definition. One may object that Scotus (*Theor. alleg.*) writes that this is not a definition but a notification, and gives as his reason that "cause" is an equivocal name, which is not defined, as stated in Logic. I reply that the Doctor is to be interpreted as speaking of "cause" taken broadly, as it coincides with "principle," and not of "cause" taken strictly, which we are now treating.

You will object first that the final cause is counted among the causes (*2 Phys. cap. 3*). But the final cause flows into nothing in the effect, since it is the terminus of the thing. Therefore a cause is not well defined as a principle that of itself flows into an effect. I concede the major; I distinguish the minor: according to real being, I concede; according to intentional being, I deny — as will be evident in the question on the final cause.

You will object second that the divine Word is the cause of the humanity assumed by it, because it is God through whom all things were made; but the Word causes nothing in the humanity; therefore the aforestated definition of cause is not legitimate. The major is evident. The minor is supported by the common theological saying drawn from Augustine (*in Ench. cap. 28*) and (*tract. 23. in Ioan.*): the works of the Trinity ad extra are undivided. I distinguish the major. The Word causes the humanity hypostatically united to itself, as God — I concede; as the Person of the Word — I deny. And thus the minor is true, since the Word alone terminates the dependence of human nature, inasmuch as the Word alone was incarnate.

You will object third that if a cause is that in consequence of whose being another follows, then a point will be the cause of a line, because a line follows from the first point; and privation will be the cause of a composite, because the generation of a composite follows from privation; and indeed the divine Word will be an effect of the Father, because the Son follows from the being of the

Father — but this is rejected by the Latin Doctors. The consequent of the major is to be denied. For in order for something to be a cause, it must not only flow into the effect, but it is also required that what is produced by the cause be other in nature — which does not apply to the Word, since the Father and the Son enjoy the same nature. For this reason the word "other" is placed in opposition, designating an essential and quidditative distinction, as I noted in Logic (*quaest. de differentia*).

You will press the point that St. Augustine (*qq. novi testamenti, quaest. 28*) calls the Son of God an effect of the Father: therefore the aforestated reply is void. Some meet this by saying that work is not Augustine's, since it does not breathe his manner of speaking. But say that Augustine speaks in the sense of the Greeks, who use "cause" and "effect" in a broad and extended sense, as I indicated above, and as the Seraphic Doctor shows (*1. dist. 20. quaest. 2. propè finem*).

Article II. How Many Kinds of Cause There Are.

On the enumeration of the kinds of causes, there was once a vigorous dispute, as one may see in Racon (*tract. de causis disp. 2. sect. 1. quaest. 2. art. 1*), the Conimbricenses (*2. Phys. cap. 7. quaest. 2. art. 1*), and the Complutenses (*ibidem, disp. 8. quaest. 2*). But now the opinion of Aristotle (*2 Phys. cap. 3. T. 28*) and (*5 Met. cap. 1. T. 2*), of Scotus (*ibidem*), and of others in common has prevailed — namely, that there are neither more nor fewer than four kinds of causes: material, formal, efficient, and final.

Note first, from the Doctor (*1 Met. in com. cap. 2*) and (*9 eiusdem quaest. 4. §. Hi sunt*), that the aforementioned causes are treated both by Physics and by Metaphysics, though these sciences consider them in different ways. For Metaphysics treats them insofar as they abstract from motion and change, while Physics treats them insofar as they include motion and change.

Note second that these causes can be compared and ordered among themselves in two ways. First, according to real being: in this order, the first cause is matter, because it is the first subject of motion; the second is form, which is drawn out from matter in potency; the third is the efficient cause, from which motion arises; and the fourth is the final cause, which is the terminus of motion. Second, according to intentional being, and in this order the ordering of causes is contrary to and the inverse of the preceding order. For what was last among them in this order becomes first. Since what is later in execution is prior in intention, as Scotus (*1 Reportat. distinct. 41. quaest. un. §. Dices*) draws from Aristotle (*7 Met.*). Wherefore in this order of intention, the final cause is first, because it is first intended by an intellectual agent; the efficient cause is second; the formal cause is third; and the material cause is fourth.

Note third that there are four and only four genera of causes. The Doctor holds this (*1 distinct. 2. quaest. 2. §. Ostenso. 5*), (*distinct. 3. quaest. 7. §. Contra istam opinionem A*), (*1 Post. quaest. 57. §. Ad 1. arg.*), and (*1 Met. in com. cap. 2*). It is proved

first from Aristotle (*2 Phys. cap. 7*): there are as many kinds of causes as there are kinds of questions, since a cause is what is adduced to explain a question. Now, regarding a physical thing, four questions are raised and answered: from what is it? — that is the efficient cause. From what is it made? — that is matter. Through what is it made? — that is form. And for the sake of what is it made? — that is the final cause. Therefore there are four kinds of causes. Second: every cause is either intrinsic and constitutive of a physical thing, or extrinsic and not pertaining to its essential composition, as the Doctor implies (*2 Reportat. distinct. 34. quaest. 1. §. Item illud malum*) and (*lib. de primo principio cap. 2. conclus. 8*). If intrinsic, it is matter and form, which intrinsically and essentially integrate and constitute the whole physical composite. If extrinsic, it is twofold: the efficient cause and the final cause. Third: a physical composite comes to be through generation; therefore it presupposes matter, from which it comes to be; form, through which matter is specified and completed; an efficient cause, by which it comes to be; and a final cause, for the sake of which it is brought about. Therefore the number of four causes is to be acknowledged.

You will object first that St. Augustine (*lib. 83. qq. quaest. 28*) writes that every cause is an efficient cause: therefore only one genus of cause should be posited, namely the efficient. I reply that Augustine is to be interpreted not as excluding other causes, which he acknowledges elsewhere, but by antonomasia, because the efficient cause has the nobler influx and the more excellent real mode of causing, which is attributed even to God. For this reason Augustine speaks of every cause by antonomasia. Christ the Lord uses this manner of speaking (*Mar. 16*): preach the word to every creature — that is, to man, who is the most excellent of all created things, according to Gregory. Or, say that Augustine is to be interpreted as speaking of every extrinsic cause, which always requires an efficient cause. For although the final cause is an extrinsic cause, nevertheless there is no final cause that is not also an efficient cause, as Scotus subtly observed (*1 distinct. 1. quaest. 5. §. Ad argumenta*), and after him Suárez (*disp. 12 Met. Sect. 3. numero quinto*).

You will object second that, beyond the said causes, there are others, such as the dispositive and the instrumental — therefore there are more than four genera of causes. Confirmation: an object moves a faculty toward knowledge of itself; therefore it constitutes another genus of cause. I reply that these are reduced to the efficient cause, as will be shown below. To the confirmation I say that the object enjoys a twofold character: motive and terminative. The former is reduced to the efficient cause, as is evident (*3 distinct. 27. quaest. 1. Quol. 13*); the latter, since it flows into nothing, is in no way a cause — for so the Scholastics say (*3 sententiarum*) that the Word alone terminated the dependence of the assumed humanity without any special influx and causality.

You will object third that the exemplar cause is distinct from the other causes; therefore it constitutes a fifth genus of cause. I deny the antecedent with the

Doctor (*1 distinct. 2. quaest. 2. §. Quantum ad 1. art. sub G*) and (*distinct. 36. quaest. 1. §. Contra ista B*), and I say that the exemplar cause is reduced to the efficient cause: for the efficient cause is of two kinds, one natural and the other intellectual, which operates through the idea and exemplar it holds in its mind, as is clear (*7 Met. Tract. 22*).

Article III. What Causality Is.

This is indeed a difficult and subtle question, on account of which, given its difficulty and the limited knowledge available, various and diverse opinions of philosophers exist. The Nominalists — by name Rubion (*2 distinct. 1. quaest. 1. art.*) — do not distinguish causality from the cause as it causes an effect. Others, whom Pontius (*disp. 37. quaest. 3*) follows, are of the opinion that causality means nothing other than union. A number of more recent authors hold that it is an action, or influx, and a certain absolute mode intermediate between a cause actually causing and its effect. The common run of Scotists, however, holds formal causality to consist in the relation of cause and effect resulting from them.

Note that a cause can be considered in two ways. First, formally, insofar as it includes a habitude and respect toward what is caused — in which sense cause and effect are correlatives. Second, fundamentally, that is, for the entity of the cause in which the aforesaid relation of cause is grounded — and in this way the cause is something absolute, namely a substance or a quality. Now Gadius (*vol. 8. fol. 93. pag. 1*) observes that a cause taken in the first way is a concrete relative, to which the power of causing proximately corresponds, and that its abstract is causality, which formally imports the relation of a causer to what is caused. Furthermore, note that it is not the same to ask through what a cause causes and through what a cause is formally denominated a cause. For a cause causes through its power and faculty, which is something absolute residing in the category of substance or quality. But it is formally denominated a cause through a relation that necessarily results from the causer itself and from the effect caused by it, as the Doctor signifies (*2 distinct. 1. quaest. 2. §. Ad 1. sub D*).

The first thesis is: causality is distinct from a cause. This is deduced from Scotus (*now cited*), and (*4 distinct. 13. quaest. 1. §. Ad huius autem F*), and (*Quol. 8*). It is proved first: that which can exist without another is not identified with it, for this is a manifest sign of the real distinction of one from the other. But a cause can exist without causality — namely when the cause does not cause, as when the builder sleeps: there is indeed a cause suited to build, but no causality. Therefore causality does not coincide with a cause. Second: that which arises from another differs from that from which it emanates. For the same thing in respect of the same thing cannot simultaneously be principle and what is principiated, cause and what is caused — just as the sun, which is the cause of rays, cannot be caused by those rays. But causality proceeds from a cause; for when a cause

causes, it is said to exercise its causality. Therefore cause and causality are not the same.

You will say that the concrete and the abstract signify the same thing and differ only in their mode of signifying, as was established in Logic: but "cause" is a concrete name and "causality" is its abstract; therefore they are in reality not distinct from one another. I say that this holds for absolute terms only, not for relatives, which are what we are speaking about here.

The second thesis is: causality is not the union of a cause, in whatever sense this be taken. This is drawn from the Doctor (*ubi supra*) and seems explicitly defended by him (*3 dist. 2. quaest. 2. §. Quantum ad 3. F*). It is proved first: plainly the same account holds for the causality of the efficient cause as for the causality of the other causes, since the definition of a cause applies univocally to all causes. But the causality of the efficient cause is not a union — as the Conimbricenses especially indicate (*1. Phys. cap. 7. quaest. 7*). The reason is that causality of the efficient cause can exist without union of the efficient cause with its effect, as when an agent acts at a distance, or when the effect is produced after the agent has perished — as when a father is dead but a son is born. Therefore neither in the remaining causes is union their causality. Second: union precedes the causality of a cause; therefore it is not its causality. The consequence holds, for what precedes is not the same as what follows. The antecedent is proved: parts must first be united with one another before they cause the whole, just as fire must first be brought close to combustible material before it burns it. The same is clear in artificial things, which are first joined and fitted together before those works are brought forth from them. Third: there can be union of intrinsic causes without their causality; therefore it is plainly established that union is not causality. The antecedent is urged: the rational soul is united to matter without any causality. For since it is created, matter exhibits no causality to its production. The same would hold for other souls promiscuously, if they were created by God and afterwards united to matter. Fourth: a thing must first exist before it is united to another, as is evident to the eye not only in natural things but also in artificial things. But form is to be united to matter in order that the whole may come to be; therefore it must exist, since union is the bond of existing things. Therefore it is presupposed already caused and drawn from the potency of matter before it is bound to it, and hence its causality has preceded — since it cannot be caused except through causality. And thus union is not causality. What Pontius adds — that this does not hold when union is the reason for placing form in the existence of being — is stated without foundation and supported by no argument. For union can never be the reason for placing form, since form can pre-exist without union; and union is an accident and a habitude of things capable of union, which must at least by nature precede the union itself. For the ground and the terminus must necessarily be pre-required and presupposed, so that a relation may emerge from them. But union is a relation

of form and matter; therefore it is not the reason for placing form, but arises from matter and form when they have been placed and jointly conjoined.

The third thesis is: nor is causality a substantial mode devised by certain more recent authors. The Doctor (*cited*) does not depart from this, and it is evident from (*lib. 2. quaest. 5. art. 2*), where I repelled at length this kind of substantial mode. Furthermore, it can be urged that in a whole there is nothing to be found besides matter, form, and the union of the two, according to the said recent authors; but none of these three is causality, as the same authors maintain, and this is evident because matter and form are substances, and union is an accident. Again: action, which according to the said Doctors is the causality of the efficient cause, is not a substance but an accident. For it holds its place in the category of quality, or in the special predicament called action. Moreover, it is present and absent without corruption of the subject — being present when the aforesaid parts cause the whole, and absent when those same parts remain together in the whole or are separated from one another. Therefore causality is not a substantial mode of said causes.

The fourth thesis is: the causality of a cause, formally speaking, is a relation to what is caused — posterior by nature to the ground, but prior by nature to the terminus. This thesis has two parts. The first part is handed down by the Doctor (*9 Met. quaest. 4. §. Sciendum*), and (*Theor. 22*), and (*4 distinct. 13. quaest. 1. §. Ad huius autem*). It is proved first: that whose concrete is a relative, its abstract is a relation — since they are of the same genus — and conversely, that whose concrete is absolute, its abstract is an absolute form, as is clear in the case of "man" and "humanity," "white" and "whiteness." But "cause" is a concrete relative, for a cause has respect to what is caused, as I observed above in the note. Therefore causality, which is its abstract, is a relation of cause to effect. Second: a relation is that which has its entire being toward another; it is a habitude toward another, as I said in Logic. But causality has being toward another, since it is the causality of some effect. I add that upon action and passion is grounded the second genus of relatives (*5 Met. cap. de relatione*); and that action, which is one of the ten predicaments, is a pure respect and relational entity, as the school of subtilists holds; and that action is the causality of the efficient cause — this is the common opinion of more recent authors. It must therefore be maintained that causality is a relation.

The second part is intimated by the Doctor (*1 distinct. 7. quaest. vn.*) and (*2 distinct. 1. quaest. 2*) and (*Quol. 1*), and is expressly defended by Canon (*3 Phys. quaest. 2. art. 1*), Bassi (*1 distinct. 7. quaest. 4*), and Palsero (*quaest. 18. Sua Pinacotheca*), against Fuente (*2 Phys. diff. 3. quaest. 2. art. 2*) and Mastrius (*disp. 5. quaest. 2*). It is proved first from Aristotle (*2 Phys. T. 14*), who affirms that generation is a way to nature. And (*3 eiusdem operis T. 21*), cited and explained by Scotus (*4 distinct. 13. quaest. 1. sub L*): action and passion are the same, like the road from Athens to Thebes and conversely from Thebes to Athens. If therefore

action, which is the causality of the efficient cause, is a way to the effect that is its terminus, without doubt action itself precedes the terminus, just as a road precedes the boundary to which it leads. And thus, in the opinion of both authors, causality of whatever kind precedes the effect to be produced by it. Second: a cause is that which of itself flows into an effect through its causality — as the efficient cause flows through action and produces its effect; for example, fire through heating causes heat, and the sun through illumination causes light. But that influx or causality of the efficient cause precedes the effect, just as motion precedes the terminus determined by the agent. For once the terminus is acquired, motion ceases. Therefore causality is prior by nature to the effect produced through it. Hence Scotus rightly adds (*Quol. 13. art. §. De tertio BB*) that action is productive, or eductive, or inductive of its terminus. He also adds that in the Godhead, through active generation, which is in the Father, the Son — who is its terminus — receives being; and the same he maintains of active spiration, through which the Holy Spirit is produced. Finally, the causality of the efficient cause — for example, elicitation, which is the action of the will belonging to the genus of action, through which praxis is produced — is referred back to the efficient cause itself, as the Doctor writes (*in prol. quaest. 4. antè §. Ista tres via N*), which is confirmed by Viguer and Lynch (*ibidem*). And what pertains to the effective principle — such as the causality of the efficient cause — precedes the effect that is its terminus, through which the terminus itself is produced, as the same Doctor also maintains (*1 distinct. 3. quaest. 6. §. Tertia quaestio Y*). And his faithful Achates, Anthony Andreae, explains this lucidly (*in com. lib. sex principiorum, cap. 2*), saying that action belonging to the genus of action — which is the relation of the transformer to what is transformed — is neither the principle "which" (for example, fire generates fire), nor the formal principle "through which" (for example, heat generates heat), but the productive principle "through which," just as heating is the productive principle "through which" heat is caused.

You will object first, against the first thesis, that the uncreated agent acts on things ad extra without any action or causality mediating between its power and the creatures founded by it. Therefore the same is to be maintained of the created agent, and thus causality is not distinct from a cause. The parity is to be denied, since the uncreated agent, on account of its infinity, can receive nothing new in itself — otherwise it would be changed — whereas the created agent, on account of its finitude, is capable of receiving something new, such as action, which is a relation residing in the agent and having respect to the terminus of which it is productive, as is clear (*1 dist. 30. quaest. 2. §. Ad argumenta, quaest. 2. R*).

You will object second, against the second thesis, that once the union of matter and form is posited, the composite is immediately caused. Therefore union is the causality of each. The antecedent is at hand: that which, once posited, is also posited, and which, once removed, is also removed, is the cause and causality of it. Since union is of this kind, it must be established as the causality of the

aforesaid causes. I reply by distinguishing the antecedent: as a necessary condition and prerequisite for the production of the whole — I concede; as its causality and productive principle — I deny. For the approach of the combustible to the combustible is indeed required for combustion to occur, but it is not its cause — it is only a condition, as I made clear above.

You will object third, against the first part of the fourth thesis, that a relation is the productive and effective principle of nothing, since it belongs to the genus of sterile things; therefore causality cannot be a relation. The confirmation is from the Doctor (*3 distinct. 1. quaest. 2. §. Ad 1. argum. D*): what is absolute in the cause immediately gives rise to what is absolute in the effect; but the relation between cause and effect is subsequent and arises and results from them once they are posited; therefore, according to Scotus, causality is not a relation. I distinguish the antecedent: a relation intrinsically advening — I concede; a relation extrinsically advening, such as action — I deny. This is how Anthony Andreae responds (*passim alleg.*). By the same answer the confirmation is dealt with; and I add that it is true of the principle "which" and of what some call the fundamental principle "through which," but not of the formal productive principle "through which," as I was explaining before the first objection.

You will press the point that every relation pre-requires and presupposes a ground and a terminus from which it arises and emanates; therefore even a relation extrinsically advening cannot be productive of its terminus. I distinguish the antecedent with Canon (*ubi supra*): a relation in the mode of first act and in quiet being, such as paternity and filiation — I concede; a relation in the mode of second act and in motion and flux, such as active generation, action, and the like — I deny. Mastrius (*cited*) objects and says that this doctrine is opposed both to Scotus and to truth. As for Scotus: in (*2 distinct. 1. quaest. 2. E*) and (*4 distinct. 13. quaest. 1*) and elsewhere, he openly asserts that a relation follows from its extremes and arises from them once they are posited in being. But as for the truth: this doctrine conflicts with it, since a relation is toward another — namely toward the terminus — and therefore presupposes the terminus already existing, and hence it does not receive being through the relation. On the contrary, Scotus plainly teaches the aforesaid doctrine both in the places cited before the first objection, and also in (*2 distinct. 25. quaest. vn.*) and (*4 distinct. 11. quaest. 2. §. Ad argumenta. Ad 1. Sub B*) — a doctrine which his most eminent and most ingenious disciples Bassi and Canon, already named, willingly receive and defend. Reason and truth are on our side. For this enunciation is true: an agent acts through action, as fire heats through heating and the intellect through diction produces intellection. Now such action belongs to the genus of action and influx, through which its terminus receives being: for through diction intellection — which is its terminus — receives being, and through heating heat is produced. Therefore Scotus and reason are with us; and the testimonies of Scotus adduced by Mastrius do not help him, because in them the Doctor speaks of a relation of the first genus, which presupposes both

extremes already produced, from which it results — or rather of a relation intrinsically advening. Nor does the argument he adduces from reason help him: for a relation is toward another — supply, already produced or to be produced through it — as I was just saying of diction, which tends toward intellection to be generated through it. That this holds in the Godhead as well, the Doctor maintains (*in 4 alleg. D*), saying that through active generation the Son of God receives being. But active generation is a relation productive of its terminus. Therefore the aforesaid distinction and doctrine of the relation of the first and second genus, both in creatures and in divine things, remains firm and stable.

If you press again that a relation depends on the terminus by which it is specified — therefore it is not produced through it — I say that it depends on a terminus not yet produced, if it is of the second genus, but to be produced through it. On the contrary: a relation, as it is a cause, and the terminus is not, but through it will be, because it is to be produced — but nothing can depend on a non-being and a non-existent. I say, given the hypothesis, that the terminus is not in completed being, but is indeed in the process of being — which has been shown above through examples to be sufficient.

Article IV. Whether a Cause Is Prior to Its Effect.

The modes of priority are adduced and weighed both in the Postpredicamenta and in (*5 Met. sum. vn. cap. 18. T. 16*) by Aristotle, and by Scotus (*ibid.*). Of the two modes in question here, the only doubt is whether a cause is prior in nature or in time to what is caused by it. On this matter, the only one I find who holds that a cause neither by nature nor by time precedes its effect — but that cause and effect are simultaneous both in time and in nature — is Paul of Soncino (*in 5 Met. quaest. 7*). All the rest commonly and unanimously maintain that a cause always precedes its effect, if not in time, at least in nature.

Note that a cause can be considered in two ways. One way is according to its absolute entity, which is denominated a cause — as in the case of a person to whom the relation of paternity belongs and accrues through the generation of a son. The other way is according to the character or relation of the cause itself, through which it has respect to the effect; for a cause, as stated above, is a concrete relative name, to which an effect corresponds as its correlative. All of this the Doctor intimates (*2 distinct. 1. quaest. 2. §. Ad 1. E*) and (*Theor. 18. 19*).

The first thesis is: a cause is necessarily prior by nature to what is caused by it, but prior in time only per accidens and contingently. The thesis is bipartite and is indicated by Aristotle (*2 Post. T. 9*) and (*5 Met. T. 1. 11*); and the Doctor receives it (*ubi supra*), and (*2 distin. Et. 1. quaest. 3. §. Tenentes ante F*), and (*3 distinct. 18. quaest. vn. §. Ad 1. K*). The first part is proved first from Augustine (*6 Trin. cap. 1*): if fire had existed from eternity, the splendor caused by it would have been coeternal to it. Nevertheless, fire would have preceded its splendor — not in

time, otherwise it would not have been coeternal to it — but only in nature. And Basil (*contra Eunomium*) says explicitly: we say that the cause is prior, and that what comes from it — supply, the effect — is posterior, these differing from each other not by any interval. That Aquinas thinks the same in this passage, (*lect. 6*) the Complutenses report (*disp. 8. quaest. 4. §. 2*). Second: that which communicates and gives being to something is prior to it at least in nature, if it is not separated from it — as is clear in the case of essential and universal predicates with respect to particulars and singulars, for these are prior in nature to those. And it is clear from the description of priority of nature adduced in (*Epit. 1. 1. quaest. 4. art. 14. num. 36*). But a cause gives being to an effect, since the effect is caused by it; therefore it is prior to it in nature. Third: that on which another depends in its becoming is prior to it in nature. For the dependence of one thing on another argues priority and posteriority of nature, which no one denies. But an effect depends in its becoming on a cause — as light on the sun, heat on fire, risibility on man, and so of the rest. Fourth: it can be urged by induction through each of the genera of causes. For since matter is the first principle of natural things and cannot exist without form, which is drawn from it, it precedes form in nature; and form, which is the other principle, precedes the composite in nature. For each is an intrinsic and constitutive cause of it, united by the efficient cause. Furthermore, the final cause moves the agent to act and is first intended by it and proposed to itself as something to be attained; and for this reason it is rightly deduced that a cause, whether intrinsic or extrinsic, always and necessarily precedes the effect that proceeds from it.

The second part is shown as follows: God is the efficient cause of created things, preceding them in time, as is clear from (*Gen. 1*): "in the beginning" — that is, in time, as the sacred interpreters explain — "he created heaven and earth." Therefore sometimes the efficient cause precedes its effect in duration. Second: nature progresses from the imperfect to the perfect over an interval of time, as is established in the formation of a human being, who first lives the life of a plant, then the life of an animal, and afterwards the life of a man (*1 de generatione animalium, cap. 3*). The same is clear in all successive things, whose measure is time. In these it is evidently seen that a cause precedes its effect in time — as a father his son, a tree its fruit, and in artificial things, craftsmen like a painter the picture he has drawn and a builder the house he has built, existing and enduring for a prior time.

The second thesis is: a cause and an effect, insofar as they are correlatives, are simultaneous in nature. The Doctor holds this (*2 d. 1. quaest. 2. §. Ad 1. E*) and (*Theor. 19*). It is proved first from (*l. praedicam. cap. de Ad aliquid*) and (*5 Metaphysica, T. 20. cap. 14*), where there are enumerated relatives of the second mode, such as the relations of cause and what is caused. Second: relatives mutually posit and mutually destroy each other — as, once a father is posited, a son is posited, and when the father perishes, the son perishes as regards the relation of filiation. Now they are simultaneously conceived and simultaneously

arise from the positing of the extremes; therefore they enjoy simultaneity of nature.

You will object first, against the first thesis, that Aristotle (*2 Physic. T. 28*) and (*5 Metaphysica, T. 3*) writes these words: "A cause in act has an effect in act." Therefore between cause and effect there is no priority and posteriority of nature, but simultaneity of nature and of time. I reply by explaining the aforesaid maxim from the Doctor (*2 dist. 2. quaest. 10. §. Et si dicatur sub B*): a cause actually causing flows actually into the effect that is actually caused by it — as when a heavy body actually descends downward to the center, such actual motion and descent proceeds from the actual cause that influences and causes such descent. Otherwise there would be an effect without a cause, which is impossible. Although therefore cause and effect are simultaneous in time, the cause is nonetheless prior by nature, with the effect emanating from it. This interpretation, as true and conformable to the text of the Philosopher, is embraced by Suárez (*disp. 26. sect. 2. n. 20*).

You will object second that what is prior in nature to another can be separated from it. For priority of nature argues priority of independence; and what does not depend on another can be disjoined from it. If therefore matter does not depend on form, it could exist without it, which is naturally impossible. And likewise, matter and form could exist joined together without a composite, which also cannot be brought about. I reply that the major is not universally true; for many things are prior in nature to others and yet are inseparable from them — as humanity and risibility, and any subjects whatsoever, from which their passions flow, cannot be separated from one another, although those are prior in nature to these, as is clear from the Doctor (*2 dist. 16. quaest. vnic.*). Again: although matter does not depend on form — since in being it precedes form — yet since it is the lowest of beings, feeble and partial, it is never naturally found without form, because form actualizes and perfects said matter.

You will object third that being is for the sake of operation (*2 Caeli 17*), and a thing cannot operate in an instant. Hence that celebrated saying: nature does not act in an instant. Therefore a cause producing an effect precedes it in time. Confirmation: the will, which is a free cause, cannot act in an instant; it requires time for deliberating what is to be done and what means are opportune and necessary for attaining the end. Therefore a cause, in order to produce its effect, must necessarily precede it in time. I concede the major; I distinguish the minor: when there is an obstacle present, and the power is feeble and operates through motion — I concede; when every impediment is removed and a sufficient power is applied — I deny. In this way the aforesaid maxim is explained. By the same token the confirmation is also answered: for a perfect will that has whatever is needed for acting — such as the will of an angel — does not require time for operation; for it immediately determines itself to one or

the other alternative, according to Scotus (*2 d. 5. quaest. 2. §. Respondeo primò. A*) and (*1 d. 39. §. Quantum ad 1. E*).

Article V. Whether a Cause Is Nobler Than Its Effect.

The question concerns the extrinsic and intrinsic cause, the equivocal and univocal, the partial and the total. Since nobility and excellence can be sought from two sources — namely from the comparison of causes among themselves and from the comparison of causes with their effects — the difficulty is raised with respect to both comparisons. Furthermore, a cause can be considered and examined in two ways. First, in the character of a cause, insofar as it gives and communicates being to an effect — and in this way a cause simply and absolutely surpasses an effect in nobility, according to that oft-repeated saying: "It is better to give than to receive," intimated in (*Alt. 10*) and defended by Lyra (*ibid.*) and Augustine (*3 contra Maximin. cap. 14*), who says that this is true in this life, where there is want — for abundance is certainly better than want, and it is better to have than to lack, better to give than to receive, better to bestow than to beg. Second, in its absolute entity — and in this way an effect sometimes surpasses its cause in nobility, as will become entirely clear from what is to be said below.

The first thesis is: a cause is absolutely said to be nobler and more perfect than its effect. This is common, and the Doctor defends it above all (*4 dist. 49. q. 0. §. Respondeo antè F*). It is proved first: the active principle is superior in nobility and excellence to the passive principle, according to the well-known saying: "The agent is nobler than the patient." But a cause is an active principle, for it flows into the effect, as is clear from its definition stated in Art. I of this Question. Therefore a cause is more excellent than its effect. Second: what is prior and independent excels in nobility what is posterior and dependent — for it is more excellent to be from oneself than from another. But a cause is prior and independent, while an effect is dependent and posterior; therefore the former surpasses the latter in nobility.

The second thesis is: the formal cause is more perfect than the material cause. This too is commonly defended by philosophers, and above all by Scotus (*in utroque opere 2. d. 12. q. 2. in calce*). It is proved first from Aristotle (*12 Met. T. 55*): "Form is the chief principle." And (*9 eiusdem operis, T. 19*): "Act is nobler than potency." But form is act and matter is potency, as I showed in its proper place. Therefore the material cause is less noble than the formal. Second: matter is nearly nothing, the lowest and most deficient of beings; but form is a beautiful, divine being, and the what-it-is of a thing. Again: matter is that which is perfected, while form is that which perfects and operates, and matter is passive. Therefore the formal cause excels the material in perfection.

The third thesis is: the composite excels each of the aforesaid causes, whether taken jointly or separately. The Doctor supports this (*Quol. 9. artic. 3*) and (*3 dist.*

1. *quaest. 2*) and (*dist. 22. quaest. vn.*). It is proved first from Aristotle (*7 Metaphys. cap. 3. T. 7*), where he establishes that form is more excellent than matter, and that the composite, which is compounded from both, surpasses them — as Scotus (*with Alex.*) interprets there. Second: what includes the perfections of matter and form and something beyond is more perfect than they — as if new light is added to pre-existing light, a greater and more excellent light results. But the composite contains matter and form as its intrinsic and essential parts, and a third entity caused by them, which is formally the whole and is really distinct from them. Therefore, etc. Third: the composite is a perfect and complete substance, while its parts are imperfect and incomplete substances, ordered toward the whole so that they may be perfected and completed. Moreover, the whole is the total and ultimate terminus of substantial generation, which subsists by ultimate and suppositional subsistence. Finally, the logical and metaphysical whole — such as a species, for example man — is more perfect than its parts, which are genus and differentia. Therefore the same is to be maintained of the physical whole, which is the composite, to which passions and actions properly belong as the total and complete principle "which."

The fourth thesis is: the equivocal efficient cause is more excellent than its effect; but the univocal cause is of equal perfection to its effect. This is deduced from the Doctor (*1 dist. 3. quaest. 7. §. Ad argumenta. R.*). The first part is proved: that which can produce several effects — not only of the same but also of diverse species — is a more perfect and eminent cause. For greater power argues greater excellence and eminence. But the equivocal cause can cause diverse effects of the same and of diverse species, as is clear of the sun, which is the cause of all living things, and of the intellect, which concurs to the production of intellections of diverse things and objects. Therefore the equivocal cause is eminent above other causes. Second: to contain many things virtually denotes greater perfection and power, as is clear of God, who virtually contains all things that can be made. But an equivocal cause is of this kind, inasmuch as it can cause many effects of a different character and species, as may be seen in the Doctor (*1 d. 2. quaest. 7. §. Ad 1. arg. principale. R.*). Therefore it holds the first place among other causes, as the Doctor expressly teaches (*1 d. 17. quaest. 2. sub 11*), (*4 d. 49. quaest. 4. M.*), and (*2 d. 25. quaest. vn. Q.*). The second part is indicated by the same Doctor (*ibid.*) and (*1 d. 2. quest. 7. R.*) and (*d. 3. quaest. 7. R.*), and is proved first: things of the same species are of equal essential perfection, as is clear of John and Francis, who share the same specific nature. But a univocal cause and its effect are of the same species, as is clear from the definition of a univocal cause; therefore they share equal essential perfection. Second: a natural univocal cause that is not impeded cannot act beyond the sphere of its activity; therefore in conferring being on an effect it does not exceed it, nor is it exceeded by it in dignity and perfection.

The fifth thesis is: the final cause is sometimes more excellent than its effect, and sometimes less noble. This is not inconsistent with Scotus, above all (*1 d. 1.*

quaest. 4) and (*d. 49. quarti quaest. 4. §. Ad argumenta. F*). The first part is urged: God, who is the final cause of man, is the most noble of all things, far surpassing all his acts and works tending toward him, which are effects of the very same being and greatly inferior and lower than him. Sometimes, therefore, the end is superior and more excellent than its effect. The second part is at hand. For sometimes a man sets for himself an end whose effect is worse than it — as one who devotes himself to philosophy for the sake of gain. Gain, which is his end, is lower and less noble than the exercise of philosophy, which is his effect.

You will object first, against the first thesis, that many effects are superior to their causes in their absolute entity — as a great fire and large flame produced from a small fire and small flame; for a small fire ignites a great forest (*Jas. 3*). Similarly, through words, herbs, and stones, marvelous effects are produced which without doubt exceed the forces of their causes. I reply that those effects arise from the application of an approximate cause to suitably disposed matter, for that reason that fire and the like grow by the addition of new matter to pre-existing matter, and these acquire greater perfection — not essential but accidental and gradual — as the Doctor hints (*1 dist. 8. quaest. 3*) and before him Augustine (*1. 1. de sermone Domini in monte cap. 23*). As for what is added, I say that it is effected through the application of natural active things to passive things, and sometimes there exists a tacit or express pact with a demon, as the Conimbricenses recently observe (*2 Physic. cap. 1. quaest. 6. art. 2*) after Augustine (*10 Ciuit. cap. 11*).

You will object second, against the second thesis: what is prior and independent excels what is posterior and dependent, as I argued above in the first thesis. But matter is prior and independent, founded by God; while form is posterior, dependent, and drawn out and produced by a created agent from matter. Therefore matter is more eminent than form. I distinguish the major: what is prior in perfection and independent — perfect and complete, such as God — I concede; what is prior in origin, imperfect by nature and incomplete, independent but tending toward perfection suited to it — such as matter, which tends toward form as its complement — I deny. The minor is to be distinguished in the same way. For the whole depends on its parts, and the species on genus and differentia — and yet the species surpasses them in perfection. This is touched on by the Doctor (*Quol. 9. art. 3*), (*3 d. 2. q. 2. §. Quantum ad 3*), and (*4 d. 12. q. 2*).

You will object third, against the third thesis, from (*7 Met. 7*): form is prior and more perfect than matter — and indeed also than the composite, because form is act formally, while the composite is in act through form. Confirmation: the composite borrows every perfection it participates from form, which gives being to the thing; therefore form is nobler than the composite. I reply that the text of the Philosopher is the opposite, for as the common run of expositors — by name Alexander and Scotus — reads there: what comes from both — that is,

the composite — is more substance, that is, more perfect, than matter and form. But if it be said that Aristotle genuinely has in his own text that form is prior and more being than the composite, the Doctor (*Quol. precit.*) meets it by saying that "prior" and "more" are to be understood not in terms of perfection but in terms of principality and independence — since the being of the more principal principle is independent with respect to what is principiated and with respect to the less principal principle. To the confirmation I deny the antecedent: for not only form but also matter — although form is more principal and effective — flows into the whole, as Scotus rightly teaches (*1 d. 8. q. 1. §. Ad quaest. D.*).

You will object fourth, against the fourth thesis, that from an equivocal cause there come forth effects more excellent than it — as from putrid matter, through the power of the sun, mice, frogs, and other such things are generated, which, being animated, are superior to the inanimate things that are their equivocal causes. Confirmation I: from parents of slow intelligence are born children of elevated and keen intelligence. And from an ass and a horse a mule is generated, which surpasses the ass. Confirmation II: an object, or its species — which is devoid of life — concurs in the production of intellection, which is a vital and spiritual act; therefore the equivocal cause is to be ranked below its effect. I reply that the excellence and superiority over the particular cause in the aforesaid effects is to be attributed to a higher, universal cause — just as the excellence and nobility of a mixture arising from the conflict of elements is attributed to the universal agent, as the Doctor hints (*2 d. 15. quaest. vn. §. Dico ergo*). Similarly, the excess of nobility of the aforementioned living things is referred back to the first cause, which supplies the efficiency and insufficiency of particular causes, with other universal causes disposing the pre-existing matter, according to Scotus (*1 d. 18. quaest. vn.*). To Confirmation I, I say that souls created by God are of unequal perfection, as I touched on above, and as Solomon indicates (*Sap. 8*) when he says: "I was a talented child and received a good soul." And Aristotle (*2 anim. cap. 9. T. 94*) observes that "those who are tender of flesh are well adapted in mind." The influences of the celestial spheres and the diverse dispositions of matter also contribute — for this reason the same Philosopher adds (*in problem. sect. 30. quaest. 1*): that the melancholic have often been seen to be more ingenious. And (*7 polit. 7*): that Asians are more cunning than Europeans, and conversely Europeans more robust than Asians. Sometimes the nobility of an effect depends on one or the other cause — as the excellence of the mule on the mare, and the excellence of intellection on the intellect. To Confirmation II: it is evident that the intentional species is not the total cause of intellection but the partial and less principal cause. Therefore vitality and spirituality proceed from the other partial and principal cause, which is the intellect, as the Doctor excellently pursues (*1 d. 3. q. 8. O*).

You will ask which causes hold the first rank of dignity. I reply that among causes the extrinsic surpass the intrinsic, for the intrinsic display potentiality and imperfection: for one is ordered toward completing and perfecting the

other, and both toward a third — namely, toward composing and constituting the composite. But the extrinsic causes designate excellence and perfection, inasmuch as they are adapted to God — the most perfect of all — who is the efficient cause and end of all things. And the Doctor teaches this lucidly (*1 dist. 2. quaest. 2. §. Quantum ad 1. art. L*). They are ordered among themselves in the following order of dignity: first is the final cause, second the efficient, third the formal, and fourth the material. In the order of nature and existence, however, the first place is occupied by the efficient cause, then matter, followed by form, and lastly the final cause.

Article VI. Whether Causes Are Causes of Each Other.

Since Aristotle (*2 Physic. cap. 3. T. 30*) and (*5 Metaphysica. 2*) put forward the proposition "causes are causes of each other" — not as a universal but as an indefinite — its interpreters labor greatly over its truth and explanation, divided into two camps. For many more recent authors, such as Suárez (*disp. 27. Metaphysica, sect. 2*) and Ruv. (*2 Physic. Tract. 8. quaest. 2*), extend that proposition to all causes, both extrinsic and intrinsic, and receive it as universal. But the ancients — by name Tatar (*quaest. ult. praedicam. ad finem scibilis primi*) and (*2 Physic. in com.*), John of Magistris (*ibid. quaest. 4. scibili 2*), Lynch (*2 dist. 12. quaest. 2*), nor do the Parisienses (*2 Physic. quaest. 1. fol. 37*) disagree, with whom agree the Conimbricenses (*ibid. cap. 7. quaest. 9. art. 2*) and Font (*3 Metaphysica, cap. 2. quaest. 16. sect. 3*) — restrict the said proposition, properly and simply, to the extrinsic causes only, namely the efficient and the final.

Note, from the irrefragable Doctor (*5 Metaphysica, in com. cap. 2*) and the Subtle Doctor (*ibid.*) and (*quaest. 1. eiusdem lib.*), and from Anthony Andreae (*eodem loco, quaest. 2*), that one cause is said to be the cause of another cause in two ways — either as to being or as to causality. Now conversely, one cause cannot be the cause of another with respect to being and existing, since, in order for a cause to cause, it must necessarily be and exist — for action presupposes the agent, and heating presupposes the heater. Wherefore it cannot come about that a causing cause has its essence and existence from another cause that is caused by it — as form, which is drawn from the potency of matter, should produce the very matter from which it is drawn and produced. But with respect to causality, it can come about that one cause moves another cause to causing — as an amiable or loved end excites and moves an agent to act, to attain it and possess it.

The first thesis is: causes are not causes of each other with respect to essence and existence. So the Doctor (*cited*) and (*Theor. 19*). It is urged first: each thing is and exists in itself prior to acting and operating, because first act is prior to second act, and being is for the sake of operation (*2 Caeli T. 17*). Therefore conversely one cause cannot be the cause of another: for if it is and exists already, it does not receive its essence and existence from another cause, since it already has its own essence and existence independently of the other cause — otherwise it would both be and not be, which is self-contradictory. And indeed it would be,

by hypothesis; and it would not be, because it would receive being from another cause. Therefore, lest we admit and include repugnance and contradiction in our theses, it must be maintained that, with respect to being and existing, causes are not causes of each other. You will say that this holds in the same genus of cause, but not in a different genus of cause. On the contrary: what is already constituted or caused in its being — whether in the same or in a different genus of cause — is not to be further constituted or caused in being, since it is presupposed already constituted and caused. If therefore with respect to being one cause is already constituted and caused, it is no longer to be constituted and caused in being by another cause — otherwise it would not be caused, or it would be caused twice, both of which are false. Again: a cause, in order to cause and communicate being to an effect, must exist. For actions belong to existing things (*1 Metaphysica 1*). Therefore the effect to which a cause gives essence and existence cannot conversely give essence and existence to its cause — just as matter, which flows into form, does not receive from form the subjective and potential being which it had prior to form. Second: a cause is prior in nature to its effect, as was proved in Article IV of this Question. But if the said proposition were true, the cause would be both prior and not prior with respect to the same thing, and both dependent and not dependent: prior as cause, and not prior as effect of another cause; dependent as effect, and not dependent as cause. Third: the same thing would be the cause of itself, which Augustine (*1 Trin. 2*) rejects. For whatever is cause of a cause is cause of what is caused. And whatever is prior to what is prior is prior to what is posterior, as the Doctor rightly pursues (*in Met. cit.*).

The second thesis is: causes are causes of each other — not in the same but in a different genus of cause — with respect to causality. The Doctor holds this (*ubi supra*). It is proved first: the final cause excites and moves the efficient cause metaphorically to acting, and the efficient cause acts from appetite for the end; while the efficient cause is the cause of the final cause as to its attainment and possession. Second: matter causes form, for form is drawn from matter; while form gives matter its formal being and specific being. Nor is any repugnance to be seen, since this mutual causality exists in different genera of causes with respect to different characters.

You will object first that Aristotle (*2 Physic. T. 30*) speaks in particular of the efficient and final causes and gives an example of them only — as moderate labor is the efficient cause of health, and health is the final cause of labor. Therefore the aforesaid enunciation does not hold for the material and formal causes. I concede the antecedent; I deny the consequent. For an argument drawn from negative authority does not conclude. Even if he affirms it of the prior causes, he does not thereby deny it of the posterior ones — especially since it is more evident in those than in these, above all in the opinion of those who do not distinguish the whole from its simultaneously united parts.

You will object second that in the same genus of efficient cause, act is the cause of habit and habit is the cause of act. Again: vapor is the cause of rain and rain is the cause of vapor. Moreover: pepper is the cause of heat in the stomach, and conversely pepper heats the stomach in the genus of efficient cause. Therefore the said proposition holds both in different and in the same genus of cause. I reply that the aforesaid examples are true not with respect to the same thing but with respect to different things — and with respect to different times: as one who was formerly someone's student now becomes his teacher, and one who was once someone's master now becomes his servant.

You will object third that the final cause is the first of all causes. But if the aforesaid proposition were true, it would not be first in all things but sometimes last. Therefore it is not true even of extrinsic causes such as the final and efficient. I distinguish the major: in intention and in perfection — I concede; in execution and in real being — I deny, as will become clearer below.

You will ask first whether that axiom drawn from (*2 de gen. T. 56*), cited by the Doctor (*4 dist. 49. quaest. 3. antè §. Hic dicitur*): "the same thing, remaining the same, always produces the same" — is true. I reply affirmatively, provided it meets three conditions. The first is that the cause be necessary and natural, since a free and voluntary cause changes and produces different effects — as the will now loves and now hates, concerning which Scotus (*2 dist. 25. quaest. vnic. §. contrà conclusionem*). The second is that it be a particular cause: for a universal natural cause produces diverse effects — for the sun hardens clay and liquefies wax, and causes other opposite effects, which the Doctor mentions (*9 Metaphysica, cap. 2. T. 4. in com.*). The third is that it be a per se cause. For from one per-accidens cause, several effects can arise — as a helmsman by his presence is the cause of the ship's salvation, and by his absence is the cause of its destruction, as Scotus notes (*2 dist. 37. quaest. unic. §. Tertiò modo*) and (*in Report. 2. dist. 34. quaest. 1*).

You will ask second whether the same thing is the cause of contraries. Aristotle answers affirmatively (*5 Met. cap. 2*), and Scotus (*ibid.*) explains the aforesaid saying — not in the same but in a different way: thus a helmsman is the per se cause of the ship's safety and per accidens the cause of its coming to grief.

Question II. On the Efficient Cause.

The first cause in execution is the efficient cause, which is called cause by antonomasia, and whose existence is evident from the effects of sublunary things and from the union of matter and form, which is obtained through the efficient cause. For matter and form are not united and a whole does not coalesce from them both except through the intervention of an efficient cause, as several writers, among whom is Scotus (*1 d. 2. q. 2. ante M*), rightly observe in Bonet (*1. Phys. cap. 1*).

Article I. How Many Kinds of Efficient Cause There Are.

For a good classification, or division, St. Augustine (*3 de Doctr. Christiana c. 2*) draws attention to the matter. Hence the Doctor adds (*1 d. 3. quaest. 2. §. Loquendo. N*) that division must precede definition. Following this precept, before we define the efficient cause, we now distribute it — above all in the immediately following and proximate members.

First, into a cause per se and per accidens, from the Doctor (*1 d. 2. quaest. 2. §. Quantum ad 1. 1*) after Aristotle (*5 Met. 2*). The former is that which by its nature and proper power attains the effect — as a builder builds. The latter is that which causes through something accidentally conjoined to it — as a musician builds.

Second, into a principal and instrumental cause, (*2 Phys. 29*) and Scotus (*d. 6. quaest. 5. §. Ad istam quaest. D*). The principal is that which has the power of acting in quiet being, through which it attains the effect — as a man cutting wood. The instrumental is that which acts in the power of another — as a saw cutting wood.

Third, into a physical and moral cause, (*5 Met. 2*) where Scotus (*in com.*) and (*4 d. 1. quaest. 4. 5*). The former truly produces the effect — as man produces man. The latter does not flow into the effect, but excites, urges, or counsels another cause to produce the effect — as one who advises or gives counsel to another to kill a man.

Fourth, into an equivocal and univocal cause. This is drawn from (*2 Met. T. 4*) and explained by the Doctor (*ibid.*). The equivocal is that which produces an effect dissimilar to itself. The univocal is that which generates an effect similar to itself and of the same species and character — as fire generates fire.

Fifth, into a universal and particular cause. This is elicited from (*5 Metaphysica, 2*) and expressly adduced by the Doctor (*ibid.*). The universal is the maker of many effects of diverse character — such as God and the sun. The particular is determined to producing one effect of the same character — as a tree, which brings forth only fruits and flowers.

Sixth, into a first and second cause. This is deduced from (*7*) and (*8 Phys.*) and (*12 Metaphysica*). It is handed down by the Doctor (*4 d. 1. quaest. 1. in fine*) and elsewhere frequently. The first cause is from itself and entirely independent — such as God alone. The second cause is from another and dependent in its being and operating — under which fall all created things.

Seventh, into an immediate or proximate cause — which attains the effect without the intervention and mediation of another, as fire generates fire — and a mediate or remote cause, which concurs to the production of the effect through an intermediary, as the sun through the medium of light heats the earth. This is touched on by Aristotle (*2 Phys. T. 53*) and (*1 Post. cap. 13. T. 30*), and by Scotus (*1 distinct. 39. §. Tertia positio*) and (*2 distinct. 37. quaest. vn. §. Ad argumenta principalia. AA*).

Eighth, into a total and partial cause. This is grounded in Aristotle (*cited*) and handed down by the Doctor (*1 distinct. 3. quaest. 7*) and elsewhere not rarely. A total cause is that which in its genus, without the aid of another, causes the effect — as fire generates fire. A partial cause is that which needs the help and concurrence of another in order to produce the effect — as the intellect requires an intelligible species acting together with it to cause intellection.

Ninth, into a natural cause — which attains the effect without any prior direction, as fire burning a forest — and an artificial cause, which produces the effect with prior knowledge and direction — as a builder constructs a house. This is intimated by Aristotle and the places of Scotus cited above.

Tenth, into a necessary and free cause. The former is that which, once all that is required for acting is posited, cannot not act — as fire properly approaching tinder necessarily burns it. The latter is that which, having all things necessary for acting, can act or not act, or suspend its action — such as the will, mistress of its own acts. This is signified (*2 Perih. cap. 3*) and (*9 Met. T. 2. 10. 12*), and expressed by the Doctor (*ibidem*).

Eleventh, into a cause called the principle "through which" — as the intellect is the principle "through which" of understanding — and a cause called the principle "which" — as man is the cause or principle "which" of understanding and of exercising the other acts of life. This is placed by Aristotle (*1 anim. T. 64*) and received by the Doctor (*4 distinct. 49. quaest. 7. ante §. Respondeo*).

Twelfth, into a cause essentially subordinated to another — among which one depends in its acting on the other, as man, the sun, and God — and a cause accidentally subordinated to another, among which one does not at all depend on the other, as great-grandfather, grandfather, father, and son. This is intimated by the Philosopher (*2 Met. cap. 2*) and explained by the Doctor (*1 distinct. 2. quaest. 2. §. Quantum ad 1. H*).

You will object that other distributions of causes are to be found in Aristotle (*2 Phys.*) and (*5 Met. cit.*). Therefore they have been enumerated by us insufficiently. The antecedent is evident: for there are universal causes, particular causes, and actual and potential causes, and precise and not precisely cause. I reply that the more important and celebrated ones have been listed, to which the rest can be reduced — as universal causes to equivocal ones, and particular causes to univocal ones.

Article II. What the Efficient Cause Is.

Some authors, such as Hurt (*disp. 9. Phys. Sect. 1*) and Arr (*ibid.*), entirely reject the definition of the efficient cause given by the Philosopher. Others, among whom is Suárez (*disp. 17. Met. sect. 1*), surround and clothe it with such great masses of difficulties that it seems entirely different from the Peripatetic definition. The common opinion, however, is that of Scotus (*5 Met. in expof. cap. 2*) and others,

who teach that it is appropriate and legitimate. The thesis is: the efficient cause is aptly defined as "the first principle whence motion and rest." So Aristotle (*2 Phys. cap. 3. T. 29*), (*5 Met. 2*), and also (*1 de gen. animalium, cap. 1*), and Scotus (*in com. 5 Met. praalleg.*). It is explained as to all its terms. "Principle" is placed as the genus. "First" is added on account of its appendages. "Whence" — that is, from which — is added to denote its difference from the other causes. For matter is that from which something is made; form is that through which something is caused; and the final cause is that for the sake of which something is made. The remaining terms, "motion and rest," are taken broadly, to signify its way, which is production, and its terminus, which is the effect. The thesis so explained is proved by the common middle: a definition is apt that consists of genus and differentia, as has been often said. But the aforesaid definition is of this kind, as I have explained above. Therefore it is correct and appropriate. I add that it contains nothing superfluous and nothing deficient, which belongs to the laws and rules of a sound definition.

You will object first that Aristotle (*1 Caeli T. 100*) defines the efficient cause in these words: "The efficient cause is the principle whence being is communicated." Hence it is said that being is communicated to some more clearly and to others more obscurely — and this is being and living — as Ferchius rightly notes (*vestig. 1. cap. 11. num. 30*). The same is intimated (*9 Met. T. 10*) and (*12 eiusdem operis, T. 30*). Therefore the aforesaid definition is bad. I reply, according to the explanation we have given above, that this definition is not really distinct from that one, except in words; and because that one seems more contracted and narrower, while this one is broader and ampler, fitting not only sublunary things, which come to be through transmutation, but also celestial things and those that are caused through creation.

You will object second that the definition of one thing does not fit another, for a definition equals the thing defined. But the aforesaid definition fits nature, which is distinguished from the efficient cause. For nature (*2 Phys. 3*) is defined as "the first intrinsic principle of motion and rest." Therefore it is not correctly stated. I concede the major; I deny the minor. For nature is an intrinsic passive principle, while the efficient cause is an intrinsic active principle.

You will object third that the efficient cause is adapted to God, the maker of all things, who does not cause through motion and change but through creation, which is not in the least a mutation. Therefore the aforesaid definition is not legitimate and genuine. I concede the antecedent; I deny the consequence, since, although creation is not properly a mutation, it can be called a mutation improperly, insofar as it is a passage from non-being to the being of a thing, as the Doctor signifies (*2 distinct. 1. quaest. 5. in fine*) and (*in Reportat. ibidem, quaest. 6*).

You will ask whether the aforesaid definition is univocal to all per se efficient causes enumerated in the preceding article. I reply affirmatively. This is

deduced from the Philosopher, who (*2 Phys.*) and (*5 Met. cit.*) gives examples of all of them; and the Doctor hints at it (*ibidem*), and Suárez expressly holds it (*disp. 17. Met. Sect. 1*), with Mastrius reluctant (*disp. 7. phys. quaest. 1*). The reason is that each of the above-enumerated causes is a principle on which the effect depends, and each in its own way flows into the effect — either as principal, or as instrumental, or as commanding and directing, or as executing, or as counseling, or as assisting, or in any other way in which a cause produces an effect in the genus and order of the efficient cause. Hence, by the Holy Fathers and sacred Theologians the Sacraments are said to be proper and true causes of grace, although in the School of Scotus they are only moral causes of it.

Article III. Whether Several Causes Can Simultaneously Produce the Same Numerically Identical Effect.

The heading of this article can be understood as concerning subordinated and disparate causes, as well as partial and total causes of different or the same order and species. This question can be agitated in two senses. First, naturally — in the affirmative of which seem to hold Ockham (*3 quaest. 1*) and (*Quol. 4. quaest. 8*), Gabriel (*3 distinct. 1. quaest. 1. dub. 4*), and the other Nominalists — while all the others, to be cited immediately below, adhere to the negative. Second, supernaturally — of which the prior opinion is that of Bonet (*2 Phys. cap. 3*), Mayr (*3 distinct. 5. quaest. 3*), Suárez (*disp. 26. Met. sect. 4*), and others who think that by divine power the same numerically identical effect can be produced simultaneously by two total causes of the same order and species. The posterior opinion is held by Scotus (*2 distinct. 1. quaest. 2*) and (*lib. de primo principio, cap. 3*), John of Magistris (*2 Phys. quaest. 4. artic. 3. dub. 1*), the Parisienses (*ibidem, quaest. 2. fol. 27*), and not a few of the Thomists, who consider it impossible.

The first thesis is: two total causes of different orders simultaneously concur to produce the same numerically identical effect. This is common, and the Doctor hints at it (*1 distinct. 3. quaest. 7. §. Ad auctoritatem sub BB*), and proves it from (*2 Phys. 26*): "the sun and man generate man." But the sun and man are two total causes of different orders essentially subordinated; therefore several total causes of different orders simultaneously co-act toward the causation of one numerically identical effect. Moreover: creator and creature are two total causes of different orders concurring simultaneously — not only toward one numerically identical effect, but toward the causation of all natural effects. Therefore the aforesaid thesis is truly held.

The second thesis is: two partial causes — whether of the same or different species — simultaneously produce the same numerically identical effect. The Doctor conveys this in the preceding thesis (*§. Ad quaest. respondeo K*), and Aristotle signifies it (*2 Phys. T. 31*) and (*5 Met. cap. 2*). It is proved from the well-known example: two men simultaneously pull the same numerically identical ship, and likewise bear the same numerically identical weight. Again: father and mother concur simultaneously to procreate the same numerically identical

offspring. And the intellect and the intelligible species, as two partial causes integrating one total cause, produce the same numerically identical intellection. It is therefore established that two partial causes simultaneously cause the same numerically identical effect.

The third thesis is: two total causes of the same order and species cannot jointly produce the same numerically identical effect, either naturally or supernaturally. So Scotus (*ubi supra*) and elsewhere. It is shown first by this argument, which Bonet (*precit.*) regards as its Achilles: that the same thing should simultaneously both exist and not exist in respect of the same thing evidently involves a contradiction. But if one numerically identical effect were caused simultaneously and at once by two total causes of the same species, the same thing in respect of the same thing would simultaneously be and not be. It would be, by hypothesis, in that it is caused simultaneously by both; it would not be, because without either one of them existing it would not be caused — since it would not have being from it — and could be caused without it, because it would be totally and adequately produced by the other. For example: Plato is generated by Sortes and simultaneously by Socrates as two jointly cooperating total causes. He can exist without either one of them being present. For if Plato is not generated by Sortes, he is generated by Socrates — and Socrates exists without the one by whom he is supposed also to be generated. But it is plainly repugnant for the very same Plato to be generated simultaneously and at once by both, since each is his adequate cause, and to be generated by only one of them, since with the other not existing he is still generated, as the other is his total cause. It is therefore impossible that both causes should concur in the said way to produce the same numerically identical effect.

Bonet meets this — and with him Suárez (*passim allegato*) — by denying the consequence of the minor. For the effect demands only to be from its causes as they flow into it; and therefore it has its being even if one of its causes does not exist. Just as if the same numerically identical light were to receive being simultaneously from two burning candles, if one were extinguished the same light would persist, because it would be preserved by the other still burning. The same is to be maintained in our case: if one cause did not exist while its effect remained, such an effect would depend on the other surviving and still remaining cause. In this way Scotus's argument, which seemed invincible, is weakened. On the contrary: the effect receives being from the causes from which it flows, since a cause of itself flows into the effect it causes. But the same effect proceeds simultaneously from two total causes, according to the adversaries — therefore it receives being from them, and cannot exist without them. Aristotle hints at this (*2 Phys. 37*), writing: "A cause in act has its effect in act." If therefore both total causes simultaneously cause and flow into the effect, the effect is plainly caused by them as existing, and essentially depends on them. Therefore it can only have its being from those very existing causes. Now the aforesaid argument proves that, given the hypothesis, the effect can be and exist

with one of the causes not existing; and so the argument remains in its force. The example adduced is not helpful but harmful: for it is one thing for an effect to be caused and another for it to be conserved. It can be conserved by one remaining cause; but it cannot be efficiently produced except by both causes — given that it totally proceeds and essentially depends from those two total causes. Wherefore, light caused by two candles, even though it can exist with only one candle remaining lit and the other extinguished, can nevertheless not be except as caused by both said candles — inasmuch as both equally cooperated together toward its causing, according to the position of the adversaries. Second: the terminus of one total and adequate cause cannot be the terminus of another total and adequate cause — as is clear from the very notion of a total and adequate terminus, and can be induced from created things. A composite is the total terminus of one matter and one form, so that it cannot be the total effect of another matter and form. And according to Aristotle (*1 Caeli, cap. 9. T. 95*), this world is the adequate terminus of matter, such that there cannot be another world, since all matter was exhausted in its founding. And in the Godhead, the Son of God is the adequate terminus of the generative power of the Father, such that it is incompatible for there to be another natural Son of God, as the Doctor rightly pursues (*Quol. 2.*). But the effect of one total cause is its adequate and total terminus — as no one denies, for the total cause fully supplies the entire need of its effect, from which the effect draws its total and adequate being, and in the causation of which the entire force and power of the cause is exhausted. Therefore it cannot come about that it is the total and adequate terminus of another total cause.

Some of Mayr's and Bonet's followers say that God provides effects so that they depend on another cause — not out of need but out of abundance. Just as a body naturally occupies only one place, but supernaturally can be in several adequate and total places, according to Scotus (*1 distinct. 20. quaest. 2*). On the contrary: what is of itself and by its very nature incapable of something cannot be made to possess it even by divine power — as a brute, being by its nature irrational, cannot be made rational; and a bodily eye, being material, cannot attain the divine essence by its vision, which is spiritual and immaterial. Similarly, since a total and adequate effect is incapable of the influx of another total cause, it cannot validly be the total and adequate terminus of that cause. But place is intrinsic to a body, and a body does not depend essentially on place — indeed, a body can exist without place, as the ultimate Heaven is not in place. But an effect without the cause by which it is produced and on which it essentially depends cannot exist.

Third: the same effect would at the same instant be produced totally and adequately — once by one total cause and once by another total cause. For since each cause obtains its own causality and total action, and likewise its own total terminus produced by it: but there is a double causality and action corresponding to the double total cause producing it; therefore there is also a

double terminus or total and adequate effect produced by the two total and adequate causes producing simultaneously.

Some more recent authors reply that both total causes with simultaneous and total concurrence flow into one and the same numerically identical effect — just as two essentially subordinated total causes, such as the sun and man, simultaneously flow together and co-act to procreate one singular man. On the contrary: either one cause produces the entire effect and the other is superfluous, contributing nothing to it — which is outside the present dispute — or both produce some part of it piece by piece, and so they are partial causes, which is not what this question is about — or both simultaneously cause it totally, and the aforesaid argument returns: that the effect is caused twice by them simultaneously according to their doubled causality. Nor does the adduced comparison help, since essentially subordinated causes are of a different order and character — one being universal and the other particular, which contracts and determines the universal to a suitable and specific matter. I add that the same must be said of two final causes as of two efficient causes with respect to the same numerically identical effect, since the account is equal for both, according to Scotus (*1 d. 2. quaest. 3*).

You will object first, against the third thesis, that what involves no contradiction can be brought about by God, as the common run of Scholastics teaches — by name the Doctor (*4 d. 10. quaest. 2. Dico ergo. F*). But it involves no contradiction for the same numerically identical effect to be simultaneously produced by two total and adequate causes. Therefore this is possible. The major is evident. The minor is shown: if God were to create two suns, and both were simultaneously to illuminate our hemisphere, that illumination would be one in number emanating and caused from them as total causes simultaneously. I concede the major; I deny the minor. To its proof I say: in that case both suns would cause that illumination partially and simultaneously; and by means of the light of the newly created other sun the illumination would grow — just as several lights placed in the same room illuminate and brighten that room more, as experience confirms.

You will object second that two priests can simultaneously baptize the same numerically identical infant and consecrate the same numerically identical host. Therefore two total causes can simultaneously produce the same numerically identical effect. The Doctor replies (*4 d. 6. quaest. 2. §. de primo argumentum*) that the argument includes two moral causes, and also two instrumental causes — but not principal and total physical causes. The reason is that moral and instrumental causes do not act and attain the effect through their own power and special influx — such as the aforesaid priests, with respect to baptismal grace and the body of Christ existing in the Eucharist. He writes the same (*in Rep. quaest. 4*).

You will object third: let there be two fires of equal power, equally disposed, properly approached to one numerically identical piece of tinder, with all impediments removed — they will totally and adequately introduce and produce one numerically identical heat and fire in it, equally concurring toward generating it, since they are natural total causes. Therefore one and the same numerically identical effect can simultaneously be produced by two total and adequate causes. I reply from Scotus (*4 d. 10. quaest. 2. §. Dico ergo ante Q*) that, given the hypothesis, each fire acts partially — for natural causes act to the extent they can. Since each strives to assimilate the effect to itself, but cannot fully render it similar to itself on account of the other cause co-acting with it toward the same effect, for this reason such an effect is partially caused by them — just as two men carrying the same weight simultaneously act partially and inadequately in bearing it, even if either one of them could carry such a weight.

You will object fourth that the first and second cause are two total causes producing the same numerically identical effect simultaneously — as God and man produce one and the same numerically identical man, even though God is a cause sufficient of itself to produce it totally, just as he alone created Adam (*Gen. 1*). Therefore there is no inconsistency in two total causes of the same kind co-acting equally and totally toward the causation of one numerically identical effect. I reply that the argument concludes with respect to causes of different orders and essentially subordinated, but not with respect to causes of the same order and accidentally ordered. This is how Lynch (*2 d. 37. quaest. vn. §. Tertio modo*) replies, and the Doctor hints at it both there and in (*2 d. 2. quaest. 3. §. In ista quaest. B*), and expressly holds it (*in Rep. 2. d. 37. quaest. 2. §. Teneo igitur, de devotione*), which he says is from two essentially ordered causes — namely the will of God and of man. Or say with Mayr (*2 d. 43. quaest. 4*) that the first and second cause are partial causes concurring to the production of one numerically identical effect.

You will say that a partial cause designates imperfection and insufficiency of a power unable to cause the entire effect; but God is distant from all imperfection, since he is most perfect and the cause of all perfections. Therefore the first cause does not have the character of a partial cause in concurrence with the second cause toward producing a common effect. I say that this holds for a cause acting partially out of impotence and need — not for a cause acting thus freely and voluntarily, having the power to cause the entire effect if it wished, such as the first cause cooperating with the second.

Article IV. Whether Several Total Causes Can Separately Produce the Same Numerically Identical Effect.

The state of this difficulty is whether an effect that was produced by one cause could also have been caused by another total cause — for example, this fire A, which was caused by fire B, could also have been caused by fire C. On this I find chiefly two positions. One is that of Averroes (*7 Met. com. 41*), Land (*1 de gen. q.*

12), Marblij (*ibid. quaest. 8*), Mal (*2 Phys. cap. 3. sect. 5. quaest. 3*), the Complutenses (*disp. 15. Phys. quaest. 4*), and other Thomists, who hold that it implies a contradiction for the same numerically identical effect to proceed from two total causes of the same order separately. The other is that of Scotus (*2 d. 20. quaest. 2*), Gabriel (*ibid.*), Suárez (*disp. 26. Met. sect. 5*), Ruv. (*2 Phys. tract. 7. quaest. 2*), Fabr. (*Theor. 42*), and others, who teach that this is possible by created and uncreated power.

Note from Scotus (*precit. §. Dico quod B*) that for the unity and identity of something — for example, a composite — only its essential and intrinsic parts are required, so that it is the same composite if it consists of the same matter and form, with whatever other extrinsic circumstances of place, time, and other conditions removed, as well as the efficient cause. For whether it has the same or different accidents, whether it is produced by one or another cause, it always remains the same essential and substantial composite participating the same essential and intrinsic parts.

The thesis is: the same numerically identical effect can be produced separately by two total and adequate causes of the same order. This is defended by the Doctor (*ubi supra*) and (*4 d. 43. quaest. 2*) and (*in Rep. 2. d. 20. quaest. 2*). It is proved first: if the state of innocence had persisted, all children of chosen parents would have been procreated; but now in the state of sin, some children were born of reprobate parents — such as Sts. Martin, Barbara, and Christina, as their acts testify. Therefore those who were begotten of the reprobate could have been generated by the elect and predestined, and hence the same numerically identical effect can separately be produced by good total causes of the same order. And this is supported by the testimony of Gregory the Great (*4 Mor. cap. 22*), who says: "If the first parent had been corrupted by no stain of sin, he would in no way have generated sons of gehenna from himself; but those who are now to be saved through the Redeemer would be born from him alone as the elect." Therefore the first argument of Scotus is firm. Those who reject it — Suárez and Ruv. (*cit.*) — must necessarily reject the teaching of Gregory and the ancient doctrine of the Scholastics as new, in order to introduce the doctrine of middle knowledge. Second: what is intrinsic and extrinsic to something does not destroy its unity and essential identity, as is clear from the preceding notable — and the efficient cause is extrinsic to the effect, since it can exist without it. Therefore the same effect can separately be produced by several causes. For if this heat had not been caused by the sun, it could have been caused by fire; and if Abel had not been begotten by Adam, he could have been begotten by Noah. This is corroborated: the same Lazarus, who was generated by his progenitors, rose by the power of Christ the Lord (*Joan. 11*): "immediately he who had been dead came forth." And faith teaches this of all men to be resurrected on the day of judgment. The reason for this is given: because the aforesaid causes possess equal and sufficient power to produce the same numerically identical effect.

You will say that God indeed, as a universal cause eminently and virtually containing all things, can do this — but not a creature, which as a particular cause is determined to one particular effect that the other cannot at all cause. On the contrary: the universality of causing all things implies only that God's power extends to effects both of the same and of diverse species; but it does not prevent a particular cause from attaining all the effects of the same species — and if one were not to cause one of them, the other would cause it, since that effect is contained within the sphere of its activity. For if this food is not eaten by Peter, it can be eaten by Paul and converted into the substance of the one nourished; and from what remains, seed is formed from which Paul generates Francis, who could have been begotten by Peter if he had eaten such food. You will say again that this cannot come about, because each cause has a certain and determined series of effects that the other cause cannot attain. On the contrary: those that participate the same specific nature enjoy the same property and power — as is clear of individuals of human nature, of which if one can laugh and understand, likewise the other can; and what one saw together can cut this wood, so can another — and if one does not perform this work, the other will. And it seems vain and ridiculous that this gunpowder, which this fire burned, another fire could not have burned if it had been properly applied and brought close to it. The order and series of effects of one cause, therefore, does not prevent such effects from being able to be produced by another cause of the same species — especially because among them there is not an essential but only an accidental subordination, as Aristotle notes (*2 Met. 2*) and (*3 eiusdem cap. 11*), which does not prevent what one individual of the same species can do from being equally possible for another, since it is comprehended within the sphere of the same activity. Second: a cause that can conserve can also produce the same numerically identical effect — since to conserve is no less a power than to effect. But two total causes can conserve the same numerically identical effect — as the same heat that is conserved by this fire can be conserved by another fire, and also by the sun and by warm air, as experience makes clear. Third: the efficient cause contributes nothing to the essential identity or diversity of the effect, since it is extrinsic to it; and the same corpse results whether a man dies by poison, disease, or the sword. Therefore it involves no contradiction for the same numerically identical effect to proceed separately from two total causes.

You will object first that a determined effect has a determined cause — as man generates man and a lion generates a lion. Therefore the same numerically identical effect cannot separately arise from two total causes. I reply that the antecedent is not universally true, as is clear of gold, which is produced both by the sun and by chemical art, and of certain animals that are generated either from putrid matter or from seed, as Scotus affirms (*1 distinct. 2. quaest. 7. §. Ad 1. R. & S.*) after Augustine (*in epist. ad Deogratias*).

You will object second that if the same numerically identical effect were to be produced separately by two total causes, it would both essentially depend on

them and not depend on them — which involves a contradiction, as the Doctor (*cit.*) argues in the preceding article. I deny the consequent of the antecedent. For a contradiction is repugnance in the same respect of the same thing for the same time and place; but this does not occur in our case. For given the hypothesis, the same effect would be produced not by both simultaneously and at once, but by only one of the two — although it could have been produced separately by both, as the Doctor (*ubi supra*) subtly and consistently infers. You will say that, given the hypothesis, this effect would per se depend not on the cause but per accidens. I say there is an equivocation in the particle "per se." For if "per se" means that the effect requires one cause such that it cannot be produced by another — I deny it. But if the term denotes that the cause flows into the effect — I concede it; yet if one cause were not to communicate being to it, another would communicate being to it. But a per-accidens cause is described as one that does not of its own proper power give being to the effect, as from the Doctor (*1 dist. 2. quaest. 2. 1. §. Quantum ad 1*).

You will object third that every agent acts through its action, which is the medium through which the agent acts and attains the effect. But one numerically identical action has only one numerically identical terminus and effect. Therefore the same numerically identical effect cannot emerge from two causes and two actions. I concede the major. To the minor I say that action is extrinsic to the effect, and the effect does not derive its unity and essential identity from it. Therefore the same effect can arise from this or that cause, through this or that action — indeed, there can be distinct actions toward the same terminus and effect, as Scotus writes (*4 distinct. 43. quaest. 3. §. Tertia opinio*) and (*dist. 13. quaest. 1. §. Ad huius autem D*).

You will press with (*8 Met. 12*): "If the agent is the same and the matter is the same, the effect will be the same." Therefore for the unity of the effect the unity of the efficient cause and action is required. Scotus meets this (*in 4. cit. distinct. 43*): if the agent is different and the matter is diverse, the effect arising from them is indeed different and diverse. But conversely it does not rightly follow that if the agent is the same and the matter is the same, the effect is the same — since the unity and identity of the effect is in no way to be sought through the unity and identity of the agent, inasmuch as one and the same efficient cause can produce several numerically distinct effects: for example, one father produces several children, and one tree produces several fruits.

Question III. On the First and Second Cause.

One of the more important divisions of causes enumerated in the preceding Question, Art. I, is into the first cause — which is God, the maker of all things — and the second cause — which is every created thing. On their causality and concurrence it is fitting to inquire into and decide the following articles.

Article I. Whether the First Cause Preserves the Second Cause in Its Being.

Some authors, whom Augustine (*5 de gen. ad litt. cap. 20*) mentions, are of the opinion that God imparted power to it and then left it, so that it acts through the power bestowed and communicated to it by him, and does nothing further concerning it and does not preserve it. Their position is touched on by Scotus (*2 dist. 37. quaest. vn. §. Si hac*) before Q, and (*ibid. in Report. quaest. 2. §. Secundo est declarandum*), and Averroes hints at it (*ibid. quaest. vn. art. vn.*). The opposite, however, is defended by the common run of theologians and philosophers, and by Scotus (*now cited*), and (*Quol. 21*), (*Quol. 12. §. De primo B*), St. Bonaventure (*1 distinct. 37. artic. 1. quaest. 1*) and (*2 distinct. 7. quaest. 2*), Alexander (*1 part. quaest. 10. num. 2. 3*), St. Thomas (*ibid. quaest. 8. art. 1*), and Henry (*Quol. 7. quaest. 3*) — who teach that God preserves all things and maintains them always, such that without his help and maintenance they could not subsist even for a moment.

Note from Vallon (*tract. form. fol. 4. pagin. 2*) after Aristotle (*7 Met. T. 59*): every question presupposes one thing and inquires about another. In the present case, it is presupposed that the second cause acts — from what is to be said below — and the question is whether it operates of itself and by its own proper power, or whether it needs the help and concurrence of God both in being and in operating. Further, it is presupposed that the second cause received being from God, since before it did not exist; and the question is whether that being which God communicated to it is preserved by God himself through a perennial and continuous influx of the same being that it received at the beginning of its creation. For preservation means nothing other than the continuation of the same being already received and previously had from God, as will be shown at length elsewhere.

The thesis is: God preserves all creatures such that without his help and preservation they would be reduced to nothing. So Scotus (*cited*), and (*1 distinct. 2. quaest. 2. §. Quantum ad 1. art.*), and (*4 distinct. 1. quaest. 1. PP.*). It is proved first from Sacred Scripture: (*Isa. 40*): "Who holds the whole world in three fingers." (*Hebr. 11*): "Upholding all things by the word of his power." And (*Act. 17*): "He is not far from any one of us, for in him we live and move and have our being." Moreover (*Sap. 8*): "He reaches from end to end mightily and orders all things gently." Second, from the Holy Fathers: Augustine (*6 de gen. ad litt. cap. 3*) and (*8 eiusdem operis, cap. 26*): "If the power of God were to cease from the things that were created, their species would immediately cease, and all nature would collapse." And (*tract. 106. in Ioan.*) he writes that God is the one who holds all things, whom the Greeks call παντοκράτωρ. And Gregory (*in 2. cit. à Seraph. ubi supra*): "All things would pass into nothing if the hand of the Founder did not hold them." Dionysius adds (*10 de divinis nomin.*): God is the one who holds all things, that is, preserves them, lest they fall into nothing. And that this was also the mind of Aristotle and his Commentator is attested by Canon (*2 Phys. quaest.*

3. §. *Ista tamen opinio*). Third: light depends no less on a luminous body than a creature depends on God, since a creature depends on God in its becoming and in its being — for God alone is independent and all other things are dependent, as Scotus notes (*4 nuper alleg.*). But light cannot exist without a luminous body, as experience establishes. Therefore neither can a creature exist without God. And the Seraphic Doctor (*primo precitato*) illustrates this with two examples: of an image imprinted in water by a seal, and of a weight suspended in the air by a hand. For the image remains in the water only as long as the seal remains, and when the seal is removed it immediately vanishes. Likewise, the weight persists in the air only as long as the hand holds it; and if the hand were no longer to hold it, it would immediately fall to the earth. So too a creature, without God's preservation and maintenance, would pass into nothing. Again: the mutable is reduced to the immutable; the temporal to the eternal; the dependent to the independent; the second to the first; potency to act; life to the living; and accident to subject. But God is immutable and the creature mutable; God is eternal and the creature temporal; God is independent, the first cause, pure act, life, and self-subsisting; while the creature is dependent, a second cause, potential, imperfect, having nothing from itself but receiving all things from God. Therefore unless it were preserved by God, it would perish and be reduced to nothing.

You will object first that an uncreated agent is no less powerful than a created agent — since the former is of infinite and the latter of finite power. But a created agent does not preserve its work after it has brought it into being — as a builder leaves the house already constructed by him and does nothing further concerning it. Therefore God too, after founding a creature, leaves it and provides nothing more concerning it, as Ecclesiasticus (15) intimates: "He left it in the hand of its own counsel." The parity is to be denied, since the works of a created agent depend on it only in their becoming, but God's works depend on him in their becoming and in their being. Therefore they require his assiduous and continuous maintenance. The Seraphic Doctor (*proxime citato*) adduces a not unfitting reason: a secondary agent presupposes principles from which it constructs its principiated and compound works — as a builder pre-requires stones, sand, lime, timber, and the like for constructing a house. But the first agent produces both the principles and the principiated things; therefore all things depend perennially on it, and without it they would fall into nothing.

You will object second that there are certain second causes that cannot fall or perish — such as an angel and the rational soul, which are incorruptible and immortal. Therefore not all created things are preserved by God. Scotus replies (*4 distinct. 49. quaest. 6. §. Hic duo. B*) that the said creatures, although they are not subject to corruption — since they lack matter, which, together with the privation conjoined to it, is the origin of corruption — are nevertheless annihilable by God. For as he created them from nothing, so he can reduce them to nothing. He writes the same (*Quol. 7. O*).

You will object third that second causes, unless preserved by God, would tend toward nothing — for as they were founded from non-being, so they would be borne toward non-being. But it is against the nature of a thing to tend toward non-being, since nature desires being and does what is better. Therefore it does not seem that a continuous preservation by God is needed for it. I concede the major; I distinguish the minor: for a thing to tend toward non-being is against its nature if the thing naturally desired non-being — I concede; for a thing to tend toward non-being is contrary to nature by reason of its own deficiency — that is, a thing cannot of itself subsist if left to itself but needs God's help and his maintenance — I concede. So the Seraphic Doctor intimates (*ubi supra*).

Article II. Whether Second Causes Are Active.

I find the Scholastics divided into three camps in this article. Some — whose position Gabriel (*4 distinct. 1. quaest. 1. dub. 3*) considers not improbable — remove all efficiency and activity from second causes, holding that God alone acts — heating at the presence of fire and cooling at the presence of water. Others — the chief of whom seems to be Avicembron (*l. fontis vita*) — suspect that spiritual things do indeed possess the power of acting, but that corporeal things are entirely devoid of it. The rest — both ancient and modern — openly defend that second causes, both spiritual and corporeal, clearly act and truly operate.

Note from Scotus (*Quol. 7. §. Sed licet P.*) that God can destroy the entities and essences of things together with their powers and faculties, or — while their essences remain intact and uninjured — suspend the actions of those powers; as he did in the Babylonian furnace. He cannot, however, remove their aptitudes and powers so that they cannot act and operate — because these are really identified with them and distinguished from them and from one another only formally, as is established (*2 distinct. 16. quaest. vn.*). Wherefore, fire can indeed be prevented or hindered by God from actually heating and burning the rightly disposed and properly approached material — but he cannot take away and remove from it the aptitude and virtual suitability of heating and burning a suitably disposed subject.

The thesis is: second causes are truly and properly active and operative. So Scotus (*precit.*) and (*1 dist. 7. quaest. vn. §. Ad 2. principale*) and (*dist. 4. 2 dist. 25. 37. §. Si hac via est vera*) and (*4 dist. 1. quaest. 1. PP. Quol. 21*). It is proved first from Sacred Scripture (*Gen. 1*): "Let the earth bring forth green grass and grass making seed, and a fruit-bearing tree bearing fruit according to its kind." Where we have God's command to work, and a little later its execution: "And the earth brought forth green grass and grass making seed according to its kind, and a tree bearing fruit." Then (*cap. 2. eiusdem libri*): "God placed man in the garden of pleasure to work and keep it, and commanded him not to eat of the tree of knowledge of good and evil" — and for the transgression thereof Adam was punished together with his wife. And because it was done by the persuasion of the serpent, the

Lord said to it: "Because you have done this, cursed are you among all animals and beasts of the earth." And (*cap. 22. eiusdem operis*), the same God commanded Abraham to sacrifice his son there — and he immediately, in obedience, was blessed by him, who said: "Because you have done this thing and have not spared your only begotten son on my account, I will bless you and multiply your seed as the stars of heaven and as the sand that is on the seashore." From these it is clearly evident that second causes act by their own power — since some, like Adam, are punished and others, like Abraham, are rewarded — because the former acted badly and the latter well. Otherwise this would be done unjustly and without cause. Likewise (*Luc. 6*) and (*Mat. 7*): "A good tree bears good fruit; but a bad tree bears bad fruit. Therefore by their fruits you will know them." St. Augustine, explaining this (*lib. contra Fortunatum*), writes: "By a good tree and a bad tree are meant not natures but our wills" — as is read (*Matt. 12*): "Either make the tree good and its fruit good, or make the tree bad and its fruit bad, for the tree is known by its fruit." Augustine (*cit.*) adds: "It is ours to choose what we will." Second, from the Holy Fathers: Basil (*Hom. 9 in Hexam.*), Damascus (*3 fidei, cap. 15*), and Augustine (*Tom. 4. suorum operum lib. 5. qq. quaest. 15*): "He — that is, God — works; we cooperate. For he does not remove but assists the good will of free choice." And there is the celebrated saying of the same Doctor (*7 Ciuit. 30*): "God so administers all things that he allows them to perform their own motions." Hence Scotus adds (*4 dist. 19. quaest. 12. §. Respondeo E*): "God has disposed, in this state, for things to co-act and to have their own proper actions." The Council of Trent is added (*sess. 6. can. 4*), expressly condemning those who think that created free will does nothing at all and conducts itself merely passively. On this at length and learnedly: Alphons (*libro 9. adversus haereses, verb. libertas*). Third, from the Philosophers: Aristotle (*cum suo Lyro 1. Perih. cap. ult.*), (*1 Phys. 2*) and (*8 eiusdem operis*), and also (*1. 9. 12. Met.*); Plato with his Academy (*citat. à D. Damasc. 9. suae Physicae*); Trismegistus and others, who constantly and unanimously embrace and defend this truth. To whom Averroes subscribes (*12 Met.*), deriding the Saracens who remove operations from things. Fourth: what is established by experience and evident to the senses must not be denied. But it is confirmed by experience and perceived by the senses that second causes act — therefore this is not to be denied. The major is clear, and illustrated by Aristotle (*1 Met. cap. 1*). The minor is freely admitted: fire heats and burns, water cools, and so of the rest. And if this be denied by anyone, he is to be thrown into fire until he confesses that fire burns — as Avicenna (*1 Met. cap. ult.*) recommends, and Scotus concurs (*1 dist. 39. §. Quantum ad 1*). In harmony with this is what the Stagirite says (*1 Top. ad finem cap. 9*): "One who doubts whether one ought to honor the gods and love one's parents needs punishment. But one who doubts whether snow is white is devoid of sense." Fifth, from (*1 Eth. 7*) and (*2 Caeli 17*), cited by the Doctor (*4 Reportat. distinct. 49. quaest. 1. propè initium*): being is for the sake of operation — which is to say, each thing exists for the sake of its own operation. Thus plants exist for flowering, a tree for bearing fruit, a man for labor, and a bird for flight, as is read (*in libro Iob. cap. 5.*). But second causes were founded by

God, as is clear (*Gen. 1*): "In the beginning God created heaven and earth." And indeed heaven was made for influencing and the earth for germinating. This is plainly demonstrated in animals by the various and diverse organs and instruments suited to exercising diverse functions and operations: thus man has hands, an ox horns, an eagle a beak, and so on for each — in which nature permits nothing superfluous and nothing idle. I add that artificial figures and forms differ from natural ones above all because the latter are living and active, while the former are dead and without action. Again: no one would be worthy of punishment or of glory. Finally: the first cause is not sleeping but always works, contemplating and loving itself; and the angels attending and ministering to it, and the other blessed, are in continuous and perennial operation — namely the vision and fruition of the divine essence. And this is daily and clearly shown by the motions of the heavens, the conflict of the elements, the powers of mixed things, and all of nature, which is the principle of motion and rest. These and similar reasons indisputably convince the supporters of the opposing opinion that not only spiritual but also corporeal things participate in the power of acting — from which dependence Gabriel, cited recently, does not dare to adhere to them but professes to follow the common opinion. Hence it is not without reason that certain authors accuse the listed writers of ignorance and folly, and rank them among heretics.

You will object first: (*Joan. 1*): "Without me you can do nothing." And (*1 Cor. 11*): "Who works all things in all." And (*2 Cor. 3*): "We are not sufficient to think anything of ourselves." And before: (*Hierem. 10*): "It is not man's way that is his, nor is it for a man to walk and direct his steps." From these and similar testimonies of Sacred Scripture it seems to be concluded that God operates and therefore creatures do nothing at all. I reply by explaining those passages: the second cause cannot do anything without the first, because the second is essentially subordinated to the first, and the first operates all things independently and in its own order. Unless the first concurs, the second cannot act — but not in the order of the second cause, which acts dependently on the first. Wherefore, for the second cause to cause, the co-causation of the first cause is required. This is what Christ the Lord hints at in the cited passage, saying: "As the branch cannot bear fruit of itself unless it abide in the vine, so neither can you unless you abide in me." The same is hinted at by St. Paul (*cited, cap. 3*): "Each one shall receive his own reward according to his own labor, for we are God's fellow workers." And (*ibid. 11*): "Not I, but the grace of God with me" — especially in meritorious works, which cannot be done without the help and grace of God preventing and accompanying, as the same Apostle shows (*ibid. cap. 13*): "If I should have prophecy and know all mysteries and all knowledge, and if I should have all faith so that I could move mountains, and have not charity, I am nothing." And then (*cap. 15*): "But by the grace of God I am what I am, and his grace in me has not been void, but I have labored more abundantly than all of them."

You will object second that the most perfect mode of acting is to be attributed to God, who is the most perfect maker. But to act alone is a more perfect mode of acting than to act with the partnership and fellowship of another. Therefore God accomplishes all things without creatures co-causing with him. I concede the major; I distinguish the minor: to act alone is a more perfect mode than to act with the partnership of another if this arises from impotence and weakness of power — I concede; but if it arises from the communication of power and virtue conferred, through which the second cause can co-act with the first to produce an effect simultaneously — I deny. For that argues greater power and perfection in an agent able to communicate the power of acting to an effect so that it cooperates with it — which craftsmen cannot do for their artificial works, as Scotus hints (*Quol. 7. §. Sed licet P.*) after St. Paul (*Galat. 3*).

You will object third that if bodies were to act, they would act either through matter or through quantity; but both matter and quantity are passive and of the genus of sterile things; therefore bodies do not possess the power of acting. Hence Augustine adds (*1 Ciuitat. 19*): corporeal causes are not to be numbered among the efficient. Confirmation: action is brought about through an intimate inpouring into the patient. But bodies cannot intimately inpour into the patient on account of quantity, which is impenetrable. Therefore bodies are devoid of action. I reply that the major is insufficient. For bodies act through form as the principle "through which," and through the bodies themselves as the principle "which," as the Philosopher notes (*1 animae T. 64*). To Augustine I say that he does not remove activity from corporeal things — since he names them causes — but indicates that they are not more powerful and swift, as spiritual and immaterial causes are. To the confirmation I say that bodies act not through intimate inpouring but through contiguity. For it is established that fire acts on water and conversely, if they are contiguous and properly brought close.

Article III. Whether the First Cause Concurs with the Second Cause in Producing Every Effect.

Although all Scholastics willingly confess and firmly maintain that the first cause co-acts with the second toward every effect produced by that second cause, they nevertheless dispute about the manner in which this concurrence takes place — whether mediately or immediately. Aureolus (*2 distinct. 38. quaest. un. artic. vn.*), Durant (*ibidem, distinct. 1. quaest. 5*), and some others cited by Augustine at the beginning of Art. I of this Question are of the opinion that God provides his concurrence to the creature only mediately — insofar as at the beginning of its formation he communicated to it the power and ability to act, through which it can totally produce on its own any effect proportioned to it. All others, however — among whom are chiefly the Subtle Doctor (*2 distinct. 37. quaest. vn. §. Propter igitur sub P.*) and (*4 distinct. 1. ad finem, quaestion. 1*), the Seraphic Doctor (*1 distinct. 45. quaest. 2. art. 2. 2. distinct. 37. 1 primo princ. quaest. 2*), the Angelic Doctor (*1 parte quaest. 105. artic. 5*) and (*3 contra Gentes cap. 70*), the Irrefragable Doctor (*1 p.*

quaest. 9. num. 2), the Illuminated Doctor (*1 distinct. 43. quaest. 7*), and the prince of the Nominalists (*Quol. 3. quaest. 4*) — teach that God is the immediate cause of all effects of second causes.

Note first and recall from what was said that between the first and second cause there is essential subordination, such that the second cannot operate without the first, even though the first can act without the second. The reason is that the second is inferior and dependent, while the first is superior and independent. Then it must be noted that the first cause freely and voluntarily causes and operates all effects of created things, even though some of them concur toward those effects naturally and necessarily — as fire toward the generation of fire — while others do so freely and voluntarily — as man in the acts of his will, whether elicited or commanded.

Note second that although the first cause is prior in priority of existence and perfection, it is not prior in priority of causality and concurrence: for both produce the common effect with simultaneous concurrence. Some Scotists deduce this from Scotus (*2 distinct. 37. quaest. un.*) in these words: "The first cause acts with priority of 'from which,' because it acts independently and more perfectly — not with priority 'in which,' such that it attains the effect before the second cause." This can be illustrated by the example of matter and form. For although matter is prior in being and existing than form, it is nonetheless not prior in flowing into and producing the composite — rather, both simultaneously concur toward causing it, as the Doctor suitably pursues (*mox alleg. §. Ad solutionem V.*). Now when two causes co-cause the same effect, if any defect happens to that effect, such a defect can proceed from one and not from the other concurring simultaneously. As (*2 Phys. 26*): "The sun and man are two causes concurring toward the generation of man." If a monster results, such a monster is not attributed to the sun but to man, on account of the excess or deficiency of matter or other causes to be given below. So the first and second cause simultaneously produce the same effect; and if any defect happens in it, that defect is imputed not to the first but to the second cause — as David, repenting, freely and publicly confesses about himself (*Psal. 118*): "My soul has failed in your salvation." For the first cause, as far as it is concerned, would perfect the effect if the second cause co-acting were willing to furnish the same perfection and rectitude to that effect. But since the second cause does not will to cause together with the first and deflects from the rule prescribed to it by God, for this reason a defect or sin happens — which is attributed to that cause alone, which is bound to obey it and does not obey, as Augustine signifies (*Psal. 70. conc. 2*) and (*lib. de cantico nono, cap. 8, qui habetur Tom. 9. operum eius*).

Note third, from the common position of Theologians — especially Scotus (*prenominatis §. Ista quaestiones*) and (*§. Ex ista solutione*) and (*in Reportat. 2. distinct. 35*) — that in sin two things are to be considered: the material and the formal. The material of sin — which is also called the substrate and the physical being

— is that positive element that is really effected by both the first and the second cause. The formal of sin is the absence of due rectitude in the second act of being, and is not in it — which is called moral evil and deformity. This is explained by the example of the wounding and killing of a man, to whose cutting of the flesh God concurs — but not to the deformity of homicide, insofar as it is prohibited by God himself in the Decalogue (*Exod. 20*): "You shall not kill." Wherefore sin formally means nothing other than the privation of rectitude, usefulness, order, and entity, according to St. Bonaventure (*2 distinct. 37. art. 2. quaest. 1*), whom St. Augustine preceded (*tract. 1. in Ioan.*): "Sin is nothing, and when men sin, they become nothing." And (*in Psal. 68*): "There is no substance, because it is iniquity, which is nothing." And David hints at this (*Psal. 14*): "The wicked man is brought to nothing in his sight."

The first thesis is: God concurs immediately with all effects of created things. This is common: Scotus (*cited at the beginning of the article*), Rich. (*1 distinct. 45. art. 2. question. 2*), and the others (*ibidem*). It is proved first from Sacred Scripture: (*Isa. 26*): "You have worked all our works for us." (*Deut. 1*): "The Lord our God who goes before you, he will fight with them with you at the same time." And (*Ioan. 1*): "All things were made through him, and without him nothing was made." And (*15*): "Without me you can do nothing." Some meet these testimonies and similar ones to be adduced, explaining them as referring to the mediate influx and concurrence of the first cause with the second. On the contrary: in those passages it is read that God works all things in all and with all — which cannot be effected without his immediate co-causation, as Christ the Lord plainly shows in the last cited passage of John, saying: "As a branch cannot bear fruit of itself unless it abide in the vine, so neither can you unless you abide in me." But the vine flows immediately into the branch — otherwise the branch itself would wither if separated from it, or if anything were intercepted between them. Therefore the aforesaid passages are to be explained as referring to immediate concurrence. Second, from the Fathers: Augustine (*lib. 1. qq. Deut. cit. quaest. 1*): "It is sufficiently shown that God is a helper in such a way that men also do something." The same (*in Deut. 20. quaest. 30*) and (*in Psal. 143*): "If through you you filled up the whole, a helper would not be necessary." Again: "If you yourself, by your will, were to do nothing, you would not be called a helper. For a helper helps one who is doing something." The same (*serm. 14 de verbis Apostoli*). If therefore God in all works helps man, as the holy Doctor says, it is plainly inferred that God is their immediate cause — like one who helps another carry the same weight or pull the same ship. And Bernard (*1 Meditationum*): "God is more intimate to internal works than to external works. But a creature is immediately present to itself and is the immediate cause of its own effects; therefore God too, who is more immediate and more intimate according to St. Bernard." Third, from (*2 Met. cap. 2*): in essentially subordinated causes, the lower cause cannot act without the superior. But the second cause is essentially subordinated to the first cause, since it is caused by it and depends on it in

being, and is a being by participation. Therefore the first immediately flows into all its effects.

You will say that this is not rightly deduced, since between the first cause and the effects of the second cause, the second cause itself mediates, from which the effects immediately proceed. On the contrary: if the second cause perishes and its effect persists — as if the generating fire is destroyed and the generated fire remains — without doubt the generated fire depends on some cause, since it is a dependent being really identified with its dependence. It does not depend on the generating fire, since that has been destroyed; therefore it depends on God immediately, since between it and God there is no longer any medium.

Fourth: the first cause absolutely and fully dominates over the second cause, since it is omnipotent — so that when it wills it withdraws its concurrence, and the second cause cannot do anything, as in (*Daniel. 3*) the burning fire did not heat or burn the three Hebrew boys. But if the first cause were not immediately causing with the second cause its action, it could not impede it — for the second cause would have the entire power of acting from itself, and whatever is required for it. The opposite of this is clear both from the cited passage and from other places of Scripture.

Fifth: God certainly and undoubtedly would not know what the second cause would do in the future, because since he is omniscient by determination of his will — whereby he has decided to concur with every efficiency of the second cause, as I said from Scotus (*tract. de scientia Dei*) — if the second cause operates independently of the influx of the first, then since it is free — as in the case of man — it can do the opposite, which God foreknows. And thus God would not be omniscient, since with a possible being posited in being, no impossible thing follows (*1 Perih. ad finem*). I add that the second cause would depend more on the first than its effect does — for the former depends immediately and the latter mediately — which seems inconvenient: that what is principiated should be more independent and absolute than the principle. Therefore the operations of the second cause depend immediately on the first. And the Author of Causes affirms this (*propof. 1*), and Averroes (*ibidem*) confirms it, saying that the first cause flows more into the effect than the second. But the second cause flows into the effect immediately; therefore so does the first. And to flow into is the same as to cause; if therefore the first flows immediately, it therefore immediately co-causes all effects of the second cause.

The second thesis is: the opinion denying the immediate concurrence of God with created things and affirming only mediate concurrence does not seem erroneous or heretical. This is deduced from the Doctor (*nuper alleg.*), who adduces arguments proving this but does not dissolve them, and (*2 Rep. dist. 37. quaest. 2. §. Secundo est declarandum*) openly says that the aforesaid opinion is probable — even though he himself with his followers defends the affirmative and common opinion. This opinion is expressly and deliberately taught by two

classical Doctors: Aureolus, a most eminent and most learned Cardinal, and Durant, most skilled Master of the Sacred Palace and most learned Bishop. Nor does it greatly displease Arr (*disp. 10. Phys. sect. 1. subsect. 2*), who strives to resolve the arguments opposed to it — as Hurt (*ibid. sect. 2. subsect. 1*) had done before him, although afterwards (*subsect. 2*) he incautiously and imprudently rejects it together with Suárez (*disp. 22. sect. 1*) and others cited by him. Nor are those far from it who maintain that God does not immediately concur with the material element of sin — among whom are eminent theologians cited by the Seraphic Doctor (*2 distinct. 37. quaest. 1. art. 1*), whom neither he nor the Master of the Sentences dared to argue against and determine the opposite of their assertion. But if according to these Authors the first agent does not immediately co-act with the second agent toward the physical act which is called the material of sin, it is not clear why it should behave the same way toward other physical acts. Sacred Scripture is added: (*Gen. 1*), where it is read that God gave the power of acting to the earth and other things, and left them thus with their powers, so that they would perform their proper works without his immediate influx: "Let the earth bring forth green grass and grass making seed," etc. Then (*cap. 2. eiusdem lib.*) it is added: "He rested from all the work which he had made" — that is, as Lyra explains, he ceased from the founding of things and completed his work. And (*Ecclesiastici 15*): "He left him in the hand of his own counsel." Augustine inclines this way (*7 Ciuit. cap. 30*): "God so administers all things that he allows them to perform their own motions." And Anselm (*l. de concordia, parte prima, cap. 8*): "God makes all actions and all motions, because he himself makes things, by which, from which, and in which they happen, and no thing has any power of willing or doing except he who gives it." And in the second part he adds: "God who predestines does not make the will by compelling it or resisting it, but by leaving it in its own being." Further: it is condemned in no Council, nor expressly reprobated by any holy Father that I have seen — as Scotus shows of the absolute principles and properties constitutive of the divine Persons (*1 dist. 26. quaest. vn.*). Moreover: the opposing testimonies and arguments can be resolved by a single distinction — namely that they hold of mediate, not immediate concurrence. And so an easy response is given to that weighty difficulty that God is not the author of evil and the cause of sins, since he does not concur with such an act. On this account the Council of Trent (*sess. 6. can. 6*) decrees that the betrayal of Judas is not from God as is the calling of Paul. Added to this are reasons urging its probability. First: a sufficient cause, once all that is required for acting is posited, produces an effect suited and proportioned to its power — without any other sufficient and total productive cause co-causing with it. As fire burns, water cools, a plant flowers, and a tree bears fruit. Therefore another sufficient and total productive cause is not required, co-causing immediately the same work; for in this way a passion proceeds from a subject without any other interposition, as light from a luminous body and risibility from man. Again: either the uncreated and created agent both simultaneously and immediately cause the effect totally — and then the effect would be

produced twice — or one of the two causes would be superfluous; or both would be partial causes partially causing it — and this derogates from God's power, which is supreme and infinite, and is sufficiently productive of any effect. Furthermore: God does not immediately concur with the effect of the material and formal cause, on account of the annexed imperfection of their causalities — which no one denies. Therefore the same must be maintained of the effect of the other causes. Finally: there are not two immediate ends; therefore neither are there two efficient causes simultaneously and immediately causing the same effect.

I have adduced these things not by opposing the common opinion, but by disputing for both sides — not asserting but opining — and by defending the aforesaid orthodox Doctors from error and heresy. But I submit myself to better judgment and to the most holy Church, and I follow the affirmative part. Therefore I respond to what is put forward for the negative part and say that the passages of Scripture and the testimonies of the Fathers affirm one thing and do not deny the other. For they affirm that creatures received the power of acting from God at the beginning of their formation, as Lyra indicates above. But they do not deny that God immediately co-causes with them — indeed, they presuppose this, since they are dependent, participated beings, essentially subordinated. What causes difficulty is the decree of the Council of Trent (*cited*), which denies that God co-acts toward evil and sin — since he is the author of goods and not the cause of evils. To this it is sufficient from Augustine (*12 Civit. cap. 7*) and Bonaventure (*2 distinct. 44. art. 1. quaest. 2*), who say that sin and moral evil have not an efficient but a deficient cause — which cannot belong to God, who is a perfecting cause. To the first argument the same is to be said: that second causes act, but dependently on the immediate concurrence of God, which they always require and continually demand, without which they cannot operate. To the second I say that both are total in their own order and cause the common effect — or they are partial, and on account of this no imperfection is attributed to God, since he causes partially not from deficiency of power but from the good pleasure of his will, thus willing to cooperate in the efficiency of all effects of creatures. To the third I say that God concurs in the genus of efficient cause, which designates no imperfection. To the fourth I say that there are two subordinated ends, just as the causes are essentially subordinated — and therefore there is no inconsistency.

Article IV. Whether the First Cause Concurs with the Second Cause Immediately by Immediacy of Power and of Suppositum.

Certain Thomists — by name Ferr. (*2 contra Gentes, cap. 7*) — maintain that God operates with created things immediately by immediacy of power and not of suppositum. The common opinion, however, is that of the Doctor (*2 dist. 37. quaest. vn. §. Ad solutionem*), Fuente (*2 Phys. quaest. 5. art. 2. diff. 1*), Conimbricenses (*ibid. cap. 7. quaest. 14. art. 1*), and others, who teach that the first cause acts with

the second in both modes — immediately by immediacy of power and of suppositum.

Note that in every agent two things are distinguished: the power of acting, which is called the principle "through which," and the agent itself, which is called the principle "which." As the power of the sun for illuminating is the principle "through which" the sun illuminates, and the sun itself is the principle "which" of illuminating. Now since in the preceding article it was established that the first agent acts with the second immediately, it remains for the present article to investigate whether it operates immediately by immediacy of power and suppositum, or not. An agent acts immediately by immediacy of suppositum when no suppositum is interposed between the agent and the patient — as the sphere of the moon acts immediately by immediacy of suppositum on the sphere of fire contiguous to it. Conversely, to act mediately by mediation of suppositum is when between the agent and the patient another suppositum mediates — as the moon acts on air, water, and the rest of the lower bodies. To act immediately by immediacy of power is when the agent acts on the patient through its own proper power inherent in it — as fire immediately by immediacy of power heats and burns wood close to it. Conversely, to act mediately by mediation of power is when the agent acts through power borrowed from another and not inhering in itself — as a craftsman operates through the power of natural active things applied to passive things. Some add another mode of acting immediately by immediacy of power: when an agent acts from itself and independently of anything else — in which sense God alone operates, since he alone is independent, while all other things depend on him and therefore act mediately, according to power bestowed and communicated to them by God.

The thesis is: the first cause concurs with the second in both modes aforesaid. The Doctor holds this (*ubi supra*) and (*ibid. in Report. quaest. 2*). The same is conveyed from him by Aretinus (*2 Phys. in annot. 2. Phys. quaest. 8*). It is proved first: the first cause is not distant from the second cause, since it is everywhere by its immensity, as is signified (*Psal. 15*): "If I ascend into heaven, you are there; if I descend into hell, you are present." And (*Act. 17*): "He is not far from any one of us, for in him we live and move and have our being." Therefore the first cause causing with the second acts immediately in both aforesaid modes. Second: that which operates through power inherent in it, with no interposed medium, causes immediately in said modes, as is clear from the preceding note. But the first cause operates with the second through its own power — indeed, through power independent of anything else — with no interposed medium, since it is intimately present to the second. Third: an action proceeding immediately from an agent argues both aforesaid forms of immediacy, since an effect cannot be caused immediately except through an action immediately proceeding from the agent itself — especially since the suppositum and its power are really identified. But God's action in causing with a creature proceeds from him immediately,

because both simultaneously attain the same common effect. Therefore both act in both aforesaid modes.

You will object: it is on everyone's lips that God acts through second causes as media. Therefore God causes with created things in neither mode immediately. I reply that the antecedent is to be distinguished, as Maurice (*in cap. 2. de primo principio*) hints. For if it is taken as meaning that second causes essentially depend on the first in being and operating, this is conceded. But if it is understood that God acts through power communicated to them at the beginning, this is commonly denied by Scholastics.

You will say that between both causes there is essential subordination; therefore one causes through the mediation of the other. I say that such subordination does not remove the aforesaid double mode of acting immediately, because although the second cause cannot operate without the first, the first does not cause prior to the second — but both simultaneously produce the common effect immediately, without any interposition of another power or suppositum.

Article V. Whether the First Cause Pre-moves and Pre-moves the Second Cause to Acting.

The family of Dominicans — by name Banez (*1 p. quaest. 14. art. 13*) and (*quaest. 23. art. 3*), Rip. (*ibid. quaest. 19. art. 8. dub. 1. cap. 11*), Alvarez (*3 de auxiliis disp. 19*), and others from St. Thomas (*1 part. quaest. 105*) — are of the opinion that the first cause pre-moves the second by a real and physical pre-motion to operating, such that without such pre-motion the second cannot act. These authors, however, are divided among themselves and split into two groups. For some are of the opinion that God pre-moves the created agent through a prior physical quality received in it, through which it is rendered capable of operating, and without which it is incapable and insufficient for acting. Others hold that nothing real and prior is placed and received in the creature intrinsically, but only extrinsically — which is the predetermination of the divine will physically pre-determining the creature itself to acting. To these are opposed Scotus (*4 distinct. 1. quaest. 1. propè finem*) and (*distinct. 12. question. 3. §. Quantum ad argum. Principale*) and (*distinct. 43. question. 3. §. Tertia opinio*), Faber (*in supp. 1. disp. 57. cap. 2. & inde*), and other Scotists — to whom are joined Molina (*1 part. question. 14. art. 13. disp. 6*), Suárez (*in opuscul. lib. 1. de concursu*), and the Conimbricenses (*2 Phys. quaest. 13. cap. 7. artic. 2*), and others commonly and firmly denying the aforesaid physical pre-motion and predetermination.

Note first that this controversy is equally agitated concerning the natural and necessary second agent as concerning the free and spontaneous one — not only with respect to effects attainable by the power of nature, but also with respect to works for which a supernatural power is required. In the present, however, we raise no question or difficulty about meritorious and supernatural works, since it is established by faith that there is a preventing grace, through which God freely

exhorts, excites, and morally moves free will and created will to acting well and meritoriously operating — as is established from the words of the Council of Trent (*can. 4. 5. sess. 6*) and the Roman Catechism (*de 1. art. Symb. 1 part. num. 22*): "Although it does not impede the efficiency of second causes, it nevertheless provides." And Sacred Scripture attests to this (*Psal. 20*): "You have prevented him with the blessings of sweetness." And (*Psal. 26*): "His mercy will prevent me." The Holy Fathers confirm this — especially Augustine (*1 ad Simplicianum, quaest. 2. in fine*): "We shall not be able to will or to run unless he moves and excites us." And the Author of Faith to Peter agrees (*capit. 32*).

Note second that the second cause in itself and in its own order is perfect. For it is the work of God, whose works are perfect (*Deut. 32.*): and before (*Gen. 2*): "Therefore the heavens and the earth were finished, and all the furnishing of them. And God completed on the seventh day his work which he had made." Now since a twofold perfection of a created thing is posited — as Lyra notes (*passim allegato*) — one to first act and the other to second act: the former is the essence of the thing, the latter its operation. The prior is ordered toward the posterior, since being is for the sake of operating (*2 Caeli 17*). The second cause is perfect and complete in first act and in its essential being; but incomplete and insufficient for causing an effect — and for this reason it needs the concurrence of the first cause, so that the effect may be produced. For there is essential subordination between those causes in being and in operating, such that the second cause can do absolutely nothing without the help of the first, as the Doctor rightly pursues (*2 distinct. 37. quaest. vn. §. Si hac via*) and (*§. Ad solutionem*) and (*in Reportat. quaest. 2*). Now two things are distinguished in a causing cause: action, and the effect produced through action — as heat is caused by fire through heating. One action proceeds from the first cause and another from the second cause; for just as causes are distinguished, so are actions, in the school of the Doctor who places action in the agent. The effect, however, is one for both causes. For both causes agree and co-cause the common effect, as two men simultaneously pull one and the same ship. Wherefore, the voluntary cause is free in eliciting and emitting its action — for it can elicit it or not elicit it, and can suspend it. But once the action is emitted and elicited, together with the action of the first cause the common effect is produced — so called because it is caused by both.

Note third, from the Doctor (*4 distinct. 43. quaest. 3. §. Tertia opinio*), that the essential subordination between the first and second cause is not something absolute produced prior by the first cause and received in the second cause, but means nothing other than the order and relation that is expressed by the name of the dependence of the second cause on the first. For since the second cause is dependent on the first, both in being and in operating, for this reason it is essentially subordinated to it — such that without it the second cause can in no way operate, as Scotus teaches (*4 dist. 1. quaest. 1. in fine*). Although however the first cause is called the moving and the second the moved, the first is

nonetheless not prior in flowing into and causing, but in perfection, nobility, and independence — or because it gives power to the second cause, which together with God's influx attains the common effect. And the first cause not acting, the second itself can in no way act — even though the second itself receives nothing in itself, as Lynch expounds (*1 dist. 2. quaest. 1. §. Sed in hoc occurrunt*).

The first thesis is: in the Peripatetic school, the first cause does not physically pre-move or predetermine the second cause to acting. This is deduced from Scotus (*Quol. 7. O. 1. dist. 8. quaest. 5*) and elsewhere, against Fuente (*2 Phys. quaest. 5. diff. 2. art. 1*) and the Complutenses (*ibid. disp. 11. quaest. 2. §. 2*). It is proved first from (*8 Phys. T. 32*): "Heavy and light things move themselves" — as fire upward and earth downward. And (*7. 33*): "A man moves a stick by his own power, which is intrinsic to him." You will say that heavy and light things are moved by the generator, not by themselves. And that the example of the stick moved by the hand is to the opposite: for Aristotle adduces that to prove the premise: "whatever is moved is moved by another," and adds: "as a stick is moved by the hand of a man." On the contrary: the Stagirite at that place gives an example of one learning and one who knows, who has the potency for learning and knowledge. But this potency for the act of knowing and speculating is intrinsic to him — namely his intellect, which is an intrinsic power of his soul. If therefore heavy and light things are moved as a knowing person is aroused to the act of knowing — since the knowing person moves himself to such an act through a potency innate to him — so too those things are moved from themselves, or by the power intrinsic to them, toward their proper place and center, if the impediment that retains them from being borne toward it is removed, as the same Philosopher adds. As for what is added about the stick moved by the hand — I say that this holds of local motion in those things that do not have an intrinsic active power of moving themselves locally but are moved by an extrinsic principle, as a stick is moved by a hand. But a man moves a stick by his own proper and intrinsic power. Second, from (*3 Phys. T. 18*): the acting second cause is not changed. But if before acting it were to receive in itself a prior quality, it would undoubtedly be changed. Therefore in Aristotle's view, the second cause is not physically pre-moved to operating. Nor is the Complutenses' exposition valid — that an agent is not changed through its action, since when a non-acting thing becomes an acting thing, it is plainly changed through its action, which it emits. Third: in Aristotle's school, the second cause is determined to act — as fire to burning and water to humidifying. Therefore a prior quality is irrelevant for determining these agents in their works and effects. Nor does the response of the Complutenses help — that these agents have indeed a determined power in themselves and in their order, but not in the order of the first cause. For the prior quality devised by the Thomists does not regard the first cause but the second, through which the second cause is said to be pre-moved. Again: animated things move themselves

from an intrinsic principle, as is more clearly evident in those that are moved by progressive motion. Again: water once heated reduces itself to its former coldness through its own innate and intrinsic power. Finally: (*2 Phys. T. 3*): nature is the internal principle of motion and rest. Many interpret this as referring to an active principle. If nature is not taken so narrowly, it obtains an active principle — as nature does what is better (*2 de gen. T. 59*). Therefore the aforesaid physical pre-motion and predetermination is to be expelled from the Peripatetic school.

The second thesis is: the natural second cause is neither pre-moved nor physically predetermined by the first cause. The Doctor holds this at the beginning of this article, and the common run of recent authors agrees. The first part is proved first: the second cause in its genus and order is perfect and complete, having an appropriate potency and sufficient power for operating and producing whatever effects are suited and proportioned to it, as I showed in the first note. Therefore it does not pre-require any physical quality pre-moving it to acting. The Thomists reply that the second cause indeed has the power of acting in the mode of habit and potency, but not in the mode of act sufficient for operating in its own order — rather, it receives this from God through the said quality received in it, through which its power is completed in first act and in the mode of a principle, and is rendered sufficient to act in its own order and genus. On the contrary: the second cause in first act and in its genus has whatever is required for acting — as the earth the power of germinating and fire the power of igniting — and God commands them to operate according to their power (*Gen. 1*): "Let the earth bring forth green grass." If the power were incomplete with respect to second act, that command and mandate to operate would be void and empty — since through it they could not operate, since they would require another prior power or the aforesaid physical quality pre-moving and exciting them to acting. Furthermore: a thing complete and perfect in its nature and essence obtains its complement in potency and power, since power flows from essence as from its source and root. But the second cause participates a perfect and complete essence; therefore it likewise participates a perfect power and power of acting — as an angel that participates an intellectual nature likewise participates a perfect intellect, which is its power. And according to the natures of things their potencies and powers of operating are had. If therefore the second cause has sufficient power in the mode of habit, likewise in the mode of act. Second: if the second cause pre-required the said quality for acting — once that quality is obtained and received in it — it would produce its proper and fitting effects without God's help and concurrence, since it would have whatever is required for operating; and so it would act independently, and the opinion of Aureolus and Durant, rejected above, would be true. The Thomists meet this by denying the consequence. For that prior quality does not exclude the concurrence of the first cause with the second for the efficiency of common effects. It is given to move, excite, and apply the second cause to

operation — which without that quality's pre-existing would not operate. On the contrary: the second cause is sufficiently moved to its objects — around which it labors — without the help of another, by those very objects: as sight by color and hearing by sound. And fire, once combustible material is presented to it, properly approached and disposed, burns it with no other principle newly instilled in it. Indeed, it seems vain and ridiculous that fire cannot act on the aforesaid object unless a prior quality caused by God is first in it — especially since natural qualities pre-existing are assigned for preparing and fitting the subject around which the natural agent must operate. Third: if the second cause were to receive in itself a quality through which it actually operates and without which it cannot operate, it would be an instrument receiving actual motion and the virtue from the principal cause — as is clear of a saw cutting wood and other instruments of art. But the second cause is not properly an instrument, since it participates its own proper power of acting remaining in it in being and in becoming, as the Doctor excellently shows (*4 distinct. 13. quaest. 1. art. 3*). Therefore no prior quality is to be posited in it for it to operate, since it possesses its own power of operating in its own order. The Thomists meet this by conceding that the second cause is an instrument of God, and therefore the power of acting is moved by God as principal agent — just as an instrument of art derives the power of acting from the craftsman, lasting as long as it is actually moved by him, and with his motion ceasing, its power and operation cease. On the contrary: the second cause is not an instrumental but a principal cause. For by Aristotle (*8 Phys. T. 33*) and (*12 Met. T. 34*) the principal cause is divided into the first — which is independent — and the second — which is dependent and essentially subordinated to the first. But each possesses its own proper power of acting enduring in it as long as it endures, and is productive of the terminus and effect it has respect to; while the power of an instrument is transient and only dispositive of the subject, terminus, and effect to be produced. Moreover: the said quality, since it is founded by God, resides and exists in the series of created things and as a second cause. If therefore every second cause for operating needs a prior quality pre-moving it, this quality too, in order to operate, needs another pre-existing one — and since the account is equal for the rest, there will be a process to infinity, which all must avoid (*2 Met. cap. 2*). Finally: since this quality is an accident, it cannot attain a substantial terminus, since an accident does not produce a substance. And no necessity, utility, or probability of it appears. Therefore it is to be exploded and banished from the Schools.

The second part is proved first: entities are not to be multiplied without necessity (*1 Phys. 7. 52*). An eternal decree and determination of God is sufficient — whereby he decided from eternity to found things in time — according to (*Psal. 14. B.*): "He spoke and they were made; he commanded and they were created." And through his power — which is his will — he created whatever he willed in heaven and on earth and in all the abysses (*Psal. 134*). And he gave them

the power by which, together with his influx, they would act and produce their proper effects — according to the prescription and definition indicated by Sacred Scripture (*Luc. 22*): "The Son of Man goes according to what has been defined; woe however to that man by whom he will be betrayed." Therefore it is empty and vain to add a new physical predetermination pre-determining second causes to acting. Second: (*8 Phys. T. 18*) and (*1 de gen. T. 56*): the natural second cause by its own very nature is determined toward producing its effects — with nothing newly instilled in it — as fire to heating and water to cooling of a subject presented and disposed to it. Therefore it is superfluous and excessive to imagine and devise a new predetermination affecting and pre-moving it to acting.

The third thesis is: the free second cause is neither pre-moved nor physically predetermined by the first cause to acting. This is defended by the Doctor (*2 distinct. 1. quaest. 2. §. Ad 1.*) and (*distinct. 16. quaest. vn. §. Alij dicunt*) and (*distinct. 37. quaest. 2. §. Quantum ad 1.*). And it is indicated by Augustine (*3 de libero arbitrio, cap. 3*) and (*lib. de gratia, libero arbitrio in initio*), and (*de cantico novo cap. 8*). It is proved first: the natural second cause is not affected by any prior quality, nor by physical predetermination, for its works — as was shown in the preceding thesis. Therefore neither is the free second cause. The antecedent was shown in the preceding thesis. The consequence is urged: if anything were an impediment, it would be the indetermination and indifference of the free second cause to acting. But this is not an obstacle but rather an advantage, since it is full faculty and absolute power to either alternative — and the free cause itself freely and spontaneously determines itself to whatever it wills, since it is mistress of its own acts, as (*Ecclesiastici 15*) makes clear: "God from the beginning created man and left him in the hand of his own counsel." Augustine adds (*passim postremo citato*): "That first man received free will intact, and God placed fire and water before him: to which you will, stretch forth your hand. He chose fire, he left water; see the just judge. What man chose, he received freely; he willed evil — this has followed him." Therefore the indifference and indetermination of the free cause is not passive — such as the potency of matter receptive of several forms — but active toward opposite acts, effects, and objects. Second: given a prior quality and physical predetermination, human freedom is injured and entirely destroyed. Freedom consists in the fact that, with all that is required for acting posited, the will can act or not act and suspend its act. But given such a predetermination, the will operates that toward which it is predetermined, such that it cannot operate anything else — otherwise it would not be predetermined. If therefore the will cannot do anything else except that toward which it is predetermined, it is plainly not free, since freedom regards opposites and thus acts on one alternative in such a way that it can act on the other, as the Council of Trent decrees (*sess. 6. cap. 5*).

The Thomists reply that the created will is determined by the first cause, while it determines itself to acting — in which way it remains free, since when it

determines itself to one thing, it can determine itself to its opposite. On the contrary: it involves a contradiction that one and the same will should simultaneously and at once be both physically predetermined and not predetermined to one thing. For it would be predetermined through the said quality, and would be not predetermined, because it determines itself — which manifestly implies repugnance. Third: free will performs a double function — namely, it can omit an act, or exercise it, or suspend it. But given and admitted such a predetermination, it is no longer in its power to administer that same act in this way, since the predetermination is established by the adversaries as such that it thus comes about and not otherwise. With predetermination therefore standing, its freedom of both exercise and specification is taken away, since it is forced to do only that toward which it is predetermined. The Thomists reply that the argument has force in the composite sense, but not in the divided sense — just as it is commonly conceded by Scholastics that the predestined in the composite sense cannot be damned, but in the divided sense can be damned. And it is on everyone's lips that: Peter sits — as he sits, in the composite sense, he cannot not sit; but in the divided sense he can not sit. On the contrary: predetermination carries a contradiction and repugnance with it, and does not remove it as the divided sense does. For the same will through it is predetermined and not predetermined — if it could do the opposite. Just as the same thing would be white through whiteness and not white through it, and the same thing would be predestined and not predestined — which is repugnant. For according to the adversaries, God pre-determines the created will to doing something, such that another and opposite thing to that predetermination never comes about nor can come about at any time — since that predetermination necessarily attains its effect. But with the first cause acting necessarily, as Scotus says (*1 distinct. 2. quaest. 2. §. ostenso*), the second cause also acts necessarily. If therefore that quality is a necessary cause and is not in the power of the will, it follows that the will itself cannot go out into an opposite act. And the same will would not be culpable in evil acts, since it would not be moved by itself but would be pre-moved by God toward producing those acts. And sin would be imputed and attributed not to man but to God — which is false and blasphemous.

You will object first, against the first thesis, from (*7 Phys. cap. 1*) and (*8 eiusdem operis cap. 5. T. 33*) and elsewhere: "whatever is moved is moved by another." But the second cause is moved to operating; therefore it is moved by the first cause — and hence a quality pre-moving and predetermining the second cause to operating must be admitted. Confirmation from the same (*7 Moraliū ad Eudemum, cap. 11*): the soul is to the body as a craftsman to his instrument and a servant to his lord. But the soul pre-moves the body and a craftsman pre-moves his instrument to acting. I add from (*Isa. 10*) that Sennacherib is called God's instrument against the Jews. If therefore the second cause is an instrument of the first cause, it follows that the second is physically pre-moved and

determined by the first. I reply that Aristotle is to be interpreted as speaking of the local motion of the celestial spheres, which comes from without — that is, from the intelligences deputed by God to move them — as the example adduced by him of a stick that is locally moved by a man makes clear. Hence (*12 Met. T. 48*) the number of celestial spheres is gathered from the number of local motions. All the more so since it is added (*8 Phys. cit.*) that certain things — as heavy and light — are moved not by another but from an intrinsic principle and determine themselves, and are not pre-determined by another. Or say that it is to be explained with respect to first act: "whatever is moved is moved by another" — that is, is produced. In this sense the second cause is likewise said to be a moved mover — moved, that is, produced, and a mover, that is, producing. Now since there is no process to infinity (*2 Met. cap. 2*), we must arrive at one that is from itself, unproduced, infinite, and independent — which is the first cause or God, producing, governing, and ruling all things. For beings do not wish to be governed badly (*12 Met. in fine*). And with respect to second act: because with the first cause moving and acting, the second cause goes out into act in its own order, and both together concur toward producing the common effect — not through something prior received in the second cause, but through the power communicated to it by God at the beginning of its formation, as the Doctor rightly notes (*4 distinct. in calce quaest. 1*) and (*2 distinct. 3. quaest. 8. §. Ad quaest. E. in solutione 3*). By this reasoning are also understood and received certain propositions — such as: "a cause acts in the power of the first cause," that is, through the power given to it by God in its creation. Again: "the second cause acts through the application of the first," that is, the first applying itself to operating, the second likewise girds itself to acting — and both attain the same common work with their own proper powers. For with the first exhibiting its concurrence, the second too — if it is natural — is ready to operate, with every obstacle removed. Again: "the first cause causes that the second causes" — namely through the communication of power and the exhibition of the necessary concurrence for causing. In this sense (*Philip. 2*) is taken: "Who works in us to will and to accomplish" — that is, according to Augustine (*22 Ciuitat. cap. 1*): "He makes those who will this, as he is said to know what he causes to be known by those by whom it is unknown" — through the power conferred on them and the necessary concurrence exhibited. To the confirmation I say that it is true of an instrument in the broad sense. For an instrument properly has no power of acting remaining in itself, but if there is any power, it receives it through the actual motion of the principal agent — as Scotus notes (*in 4. cit.*) and (*distinct. 13. quaest. 2. §. De tertio CC.*). That that passage admits this sense is clear, because the body is a companion of the soul, and from both the animated whole is constituted, which produces the acts of life — called the operations of the whole (*primo animae T. 64*). And the servant acts by his own power, even though he is subject to the command of his lord. Say the same of the testimony of Scripture, as is clear from (*cap. 14*) of the same book, where the crimes committed by Sennacherib are narrated.

You will object second, against the second thesis: the second cause is excited, moved, and applied by the first cause to operating, since it is a dependent, participated being, able to do nothing without the concurrence of the first cause. Therefore the second is physically pre-moved and predetermined by the first. The antecedent can be denied unless it is understood in the way I explained above. For fire approached to tinder, without any excitation and motion by another, burns it — with the first agent concurring with a simultaneous concurrence, which every second cause needs in order to operate, as the Doctor excellently explains (*2 distinct. 37. §. Ad solutionem. V.*).

You will object third, against the third thesis, many testimonies of Sacred Scripture — especially (*Iob. 12*): "Who changes the heart of princes." (*Prov. 21*): "The heart of the king is in the hand of God, and he will turn it wherever he wishes." (*Hierem. 10*): "It is not in man's way, and by God the steps of a man will be directed." The Council of Trent seems to hint at the same (*sess. 6. can. 4*), and Augustine is not far from it (*serm. 94 de tempore*) in these words: "Because God so works in us that we also work." And Scotus (*4 distinct. 49. quastion. 6. §. Dico ergo K*) says that the will of the Blessed is impeccable because it is anticipated by the divine will lest it fall into sin. I reply that these and similar things are to be adduced as true of good and meritorious works — for the effecting of which I noted in the first note that a preventing grace is required. Therefore, if any pre-motion is given, it is moral and not physical. Especially because God wills certain things absolutely, to which will nothing can resist (*Rom. 9*). Now God not concurring, a creature can do nothing — and thus God always wills to co-act toward the beatific act, but not toward its opposite, from which sin can follow. Hence in the composite sense the Blessed is impeccable, according to Scotus (*precit. F.*). And I showed at length in Moral Philosophy (*dub. 7. art. 2. 1. 3. q. 2*).

You will object fourth: the same Doctor (*mox. cit. K*) writes that it is not against the nature of the created will to be determined by the uncreated will. Therefore according to Scotus, physical pre-motion and predetermination is in accordance with the second cause and is not expelled from his school. I concede the antecedent; I deny the consequence. For the second cause is essentially subordinated to the first cause and is bound to conform to it and submit to it. Therefore when it wills, in certain works — as in the beatific act — it anticipates the created will lest it go out into an opposite act. But in other operations it is physically pre-determined by nothing intrinsic or extrinsic.

Article VI. Whether the Action of the First and of the Second Cause Is One.

There are two ways of speaking in this article. One is that of the Thomists, whom Suárez (*disp. 22. Met. Sect. 3*), Hurt (*2 Phys. disp. 10. sect. 3*), and other more recent authors follow — who hold that the action of the first and second cause concurring toward causing the common effect is one. The other is that of Scotus (*2 d. 37. quaest. vn. §. Ad solutionem*), Lynch (*ibid.*), Mayr (*d. 43. quaest. 4*) and (*1 d. 43*

§ 44. *quaest. 7*), Racon (*2 Phys. tract. de causis, sect. 3. quaest. 1. in solutione 2. obiectionis*), and all those who defend that action is in the agent — who teach that the action of the first and second agent producing the common effect is double. It is to be presupposed from what is to be said elsewhere that action is taken in two ways: for action of the genus of quality — called "acted action," which is the terminus and effect of the agent, as intellection is the terminus of the understanding and vision of the seeing — or for action of the genus of action, which is called the production, causality, and influx of the agent, as heating is the action of the heater and cooling of the cooler.

The thesis is: the actions of the first and second cause co-causing the common effect are distinct. This is deduced from Scotus (*ubi supra*) and (*in Rep. quaest. 2*). It is proved first: distinct agents participating distinct powers obtain distinct actions when they simultaneously cause the same effect — as is clear of two candles illuminating the same room and of stars illuminating our hemisphere, from which distinct lights, illuminations, and splendors are seen to proceed. And if only one power were in one or two agents and supposita, only one action proceeds from them — as in the Godhead, the Father and Son enjoying one spirative power, by one spiration breathe forth the Holy Spirit and are called one spirator. Likewise, the three Persons possessing one creative power go out simultaneously into one creation and are called one creator. But God and a creature are two agents participating distinct powers of acting; therefore their actions toward the common effect are distinct. Hurt (*precit.*) replies that the argument holds for disparate causes, but not for essentially subordinated ones, such as the first and second agent. On the contrary: essential subordination means nothing other than the order and habitude of the inferior to the superior and of the dependent to the independent — which belongs to the genus of sterile things and is irrelevant to the unity or multiplicity of action, which is sought from the unity or plurality of power and productive principle, as the argument clearly shows. Second: from distinct causes, distinct influxes, causalities, and actions emanate — as is clear from the definition of cause, which is a principle flowing of itself into an effect. But the first and second agent are distinct causes — for one is uncreated and infinite, the other created and finite — and through distinct actions they cause the same effect. Third: particular causes simultaneously attaining the same effect co-act through distinct actions — as is clear of the object and intellect co-causing the same intellection, and of father and mother begetting the same offspring. But God and a creature are, as it were, two partial causes co-causing the same common effect — as the Doctor does not deny in the mentioned passage. Therefore both causes co-act through distinct actions. I add that if the action of both is one — since divine action is independent, unparticipated, and infinite, identified with God — the created action that coincides with it, according to the adversaries, will likewise be such. Moreover: from the Scholastic Doctors and the sacred Councils, in Christ the Lord — in keeping with his double nature existing in one suppositum of his — a

double action is distinguished: divine and human. The former is devoid of merit, the latter participates in merit; the former is eternal, the latter temporal. These and similar predicates argue no small distinction between the aforesaid actions.

You will object first from Scripture: (*1 Cor. 12*): "Who works all things in all." And (*Philip. 2*): "Who works in us to will and to accomplish." Explaining this passage, Augustine (*1 de gratia Christi, contra Pelagium c. 5. 1. 2. cap. 25*) says that God concurs toward the ability, the willing, and the operating. And (*l. de praedestinatione, & gratia cap. 11*) he adds: "From him we have willing, because he calls and illumines; from him accomplishing — since it belongs to us to strive with the good gifts he has given and to will." But willing and accomplishing designate action; therefore God concurs not only toward the effect but also toward the action — and hence the action of a creature does not differ from the action of God. I reply to the first testimony: God works all things in the order of the first cause, not in the order of the second cause. For there the divisions of graces and talents are enumerated, according to which each one must work and attain the crown of glory. Therefore from that passage it cannot in any way be gathered that the action of God and of a creature is one in producing the common effect. To the second I say that the Apostle is there speaking of good and meritorious works, for the effecting of which a preventing grace is required — as Augustine's interpretation, adduced above, indicates — without which no one can hope well, believe, and act, as the Council of Trent decrees (*sess. 6. can. 5.*). Or he speaks of action of the genus of quality, which is the terminus and effect of the production of both causes — as I showed above in the presupposition. But not of action of the genus of action, which is doubled according to the doubling of causes — as the same Apostle hints there, saying: "with fear and trembling work out your salvation."

You will object second: God is the immediate cause of all created things, as I showed in the preceding article. But the action of the second cause is counted in the series of created things; therefore its immediate cause is God, and accordingly the action of the second cause is not distinct from the action of God. I distinguish the major: if they are termini and effects of it — I concede; but if they are ways to its termini and effects — I deny. As is clear of relations, which are not immediately produced by God but arise from the positing of the extremes. Likewise action — which is a relation extrinsically advening, from Scotus (*4 d. 13. quaest. 1*) — does not proceed immediately from God. You will say: if the action of the second cause does not depend immediately on the first cause, then it is independent and unparticipated — such as the action of the first cause. The consequence is to be denied. The reason is that the action of a creature cannot attain its effect except with the first cause concurring. Therefore it is dependent and participated. You will press: if this is true, then likewise the action of God is dependent, since it does not go out into effect except with the second cause co-causing. The parity is denied, since the first cause from its own

good pleasure concurs in this way — whereas if it wished it could produce the entire effect. But the second cause, unless it is helped, cannot go out into the effect; and therefore it is always dependent in being and in operating.

You will object third: if we distinguish the action of the creature from the action of God concurring toward the same effect, we fall into the opinion of Aureolus and Durant, commonly rejected — since a creature through its own power and action could attain the effect without God's help, as those authors suspect. A broad distinction between us and those Doctors is to be drawn. For they hold that the second cause through the power given to it by God at the beginning of its founding, without any concurrence of God, causes the entire effect. But we hold that absolutely no effect whatsoever can be produced by a creature unless God co-acts and flows into it.

Article VII. Whether the First Cause Determines the Second Cause as to the Specification and Exercise of Acts.

Two things are proposed and inferred in the heading of the present article. One is whether the first cause determines the second with respect to the specification of acts, or the second determines the first — as man determines God's concurrence toward the generation of man and not of something else, and so for the rest according to their species. The other is whether the first cause determines the second with respect to the exercise of acts and their singularity — as Peter begets Francis and not Anthony. From which the determination of the generation of Francis and not of Anthony proceeds — from God, or from Peter? On the first part, almost all maintain that the determination of the specification of acts proceeds from the second cause. For fire generates fire and not water — which is attributed to the generating fire, not to God concurring toward its generation. On the latter part, the Scholastics disagree among themselves. For some — whom Racon follows (*quaest. 3. de concursu Dei cum causis secundis, propositione 2. Sect. 3*) — attribute the determination of singular acts to the circumstances and conditions of the object and to singular dispositions. The rest commonly refer it to the first cause.

Note first that one thing is determined by another in two ways. One way is through an intrinsic and essential principle — as a species is determined by a differentia and an individual by haecceity — and of this in Metaphysics. The other way is through an extrinsic and effective principle — which is what is at stake here. For since the common effect is caused by the first and second cause, it is not beside the point to investigate from which cause it derives its specific and individual being — from the first or from the second cause? And this has already been illustrated with examples at the beginning of this article.

Note second that the indetermination touched on by us in the preceding article — from the Doctor (*1 d. 3. quaest. 7. §. Ad auctoritatem. BB*) — is twofold: passive and active. Passive indetermination belongs to matter, which by its very nature

is receptive of all forms as its perfections; and likewise to any subject — whether substantial, which receives common accidents in itself, or accidental, such as quantity receptive of qualities. Active indetermination belongs to the equivocal and universal cause with respect to several disparate effects — as the sun producing grass, plant, and tree — or contrary effects — as the same sun hardening clay and liquefying wax. And to the univocal cause producing several effects of the same species — as man generating several individuals of human nature. Again, to the natural cause whose indifference is determined by the object — as the intellect, which is indifferent to understanding whatever is intelligible, is determined by the object presented to it: for example, by a rose placed before it around whose consideration it is occupied; and the sun, whose power is diffused toward all sublunary effects, is determined by the proximate dispositions of the material at hand — as if in it there are prior and necessary dispositions for generating a plant, it generates a plant; if there are due preparations for generating a frog, it generates a frog; and so for the rest. Also, to the free and voluntary cause, which is indifferent to contrary acts — such as willing and not willing — and to contradictory acts — such as willing and not willing. This the Doctor notes (*9 Met. q. 15. 4. d. 12. q. 3. §. Dico ergo. M.*). Now this is the cause that of its own accord determines itself to acting or not acting — which is the most important distinction drawn between a natural and a free cause. Note third, from the tract on the knowledge of God (*disp. 3. quaest. 4*), that God from eternity foreknows all things individually and by decree of his will determines what he has done and will do in time with second causes — whether free — such that God's concurrence is certain and determined: not antecedent, nor subsequent, but simultaneous and concomitant according to the requirement of things and their determination. For God, perceiving and foreseeing the natural and free tendencies of second causes toward objects, leaving them in their own hand and power, has by his will decided to concur toward their performing of works and to co-cause according to those tendencies and powers — as Scotus rightly notes and teaches (*3 d. 17. quaest. vn. at 2. E*), and which Hilary (*9 Trin.*) and Augustine (*in Ench. 95*) indicate.

The first thesis is: the concurrence of the first cause, as to species, is limited and determined by the action of the second cause to co-causing the common effect. This is deduced from the Doctor (*1 d. 3 quaest. 7. §. Ad auctoritatem. BB*). It is proved first from the first book of Genesis, where at God's command the earth brought forth green grass and grass making seed according to its kind, and a tree bearing fruit and having each seed according to its kind. And a little later: "which the waters had brought forth according to their species, and every winged thing according to its kind." Second, from St. Dionysius (*cap. 4. de divinis nominibus*), who writes that God operates all things uniformly, while diversity is from second causes. Third, from (*2 Phys. 26*): "The sun and man generate man." Where the action of man, who is the lower cause, limits and determines the action of the sun, who is the universal cause. But God is a higher and more

universal cause, and a creature is a lower and more particular cause; therefore the action of the latter determines the action of the former as to species. Fourth: an effect produced by the first and second cause is rendered more similar to the second cause than to the first, as is clear in causes — above all univocal ones. A lion, with God cooperating, generates a lion; man generates a man similar to himself. The same happens in the free cause, which determines itself to a specific act — for example love or hatred — as is deduced from (9 *Met. T. 3*) and Scotus (*ibid.*) and (*quaest. 15 eiusdem lib.*).

The second thesis is: as to the exercise and singularity of acts, the second cause is determined by the first. This is gathered from Scotus (4 d. 43. *quaest. 3. §. Quantum ad illum art. 1*) and (§. de 2. art. N.) and (*ibid. in Report.*). It is urged first: the second cause is indifferent and undetermined to several numerically distinct acts and effects — of which it is the productive cause separately and not jointly. As Peter is indifferent and undetermined to generating Paul, or John, or other singular men — of whom he has the generative power. God meets this indifference and indetermination — and supplies the defect of whatever second cause — and limits and determines it first to the generation of Paul, then of John, and the rest. Hence, at an opportune time he willed and decreed that from St. Monica and her husband, St. Augustine would be begotten — whom he would afterwards use to defeat the heresies of that time. And from Pietro Bernardone and his wife Pica, St. Francis would be born — who would set afire a cooling world with the fire of divine love. And from such parents, St. Bonaventure would be procreated — who would illustrate the Minorite Order and bring it to better fruit. Therefore from the first cause comes the determination of the singular acts and individuals of the second cause. You will say: if the first cause determines the second to singular acts and individual effects, then physical predetermination, rejected above, is admitted. The consequence is denied. For there is a broad distinction between determination and predetermination. For the latter regards first act, or the power of the creature, in order to supply its insufficiency and complete its potency, as the Thomists say. But the former regards second act — so that this or that effect may proceed from the creature. Therefore all things were determined by God from eternity, as I noted above in the third note — but not predetermined. For that seems to take away both the contingency of things and created freedom, as was sufficiently shown above.

Second: as a king stands in his kingdom, so God stands in the world — Aristotle assenting (*in calce 12. Met.*). But a king in his kingdom determines these or those tasks to be performed by his clients and administered by his subjects. And the Centurion is an example (*Matt. 8*): "I say to this man, go, and he goes; and to another, do this, and he does it." It is also clear of a craftsman, who determines wax to this or that figure and clay to this or that vessel to be formed. Similarly then, God the supreme King of all — whose providence does not fail in its disposition, who orders all things sweetly — decrees and determines a creature

to performing this or that effect. And as the most wise craftsman he has decided that the creature make this vessel for honor and that one for dishonor — since only in his sight is the number of the elect to be placed in heavenly happiness known. Third: if anything were an obstacle, it would be above all that this function does not belong to God — especially on account of the circumstances of place, time, and the like, from which the determinations and singularities of the acts and effects of the second cause seem to be drawn. But these do not impede, since individuals and singulars abstract and prescind from these — and in the same place and time, several similar or dissimilar things can exist; and also in another and different place and time. For one who is now begotten at Nicaea could have been generated before, both here and elsewhere. Therefore the aforesaid circumstances are very remote and irrelevant to the determination of the singular effects of the second cause, and therefore this whole must be rejected and referred back to the first cause. And the same reasons hold for the spontaneous and free agent — to which I now subjoin the following. Since the individual differences of singulars escape our intellect, and the will is not borne toward the unknown, consequently the will itself does not determine itself rather to one act than to another, but is determined by the first cause.

You will object first, against the first thesis, that the account seems equal for the acts of the second cause in species as for those same acts in the individual and singular. But the second cause is determined by the first toward the latter — as was proved in the first thesis. Therefore also toward the former. The minor was proved in the first thesis. The major is urged: both causes equally and in their own order provide and exhibit their simultaneous concurrence toward the efficiency of all of them. But in co-acting, the second cause is always inferior and more contracted than the first, since it is essentially subordinated to it.

Confirmation from (2 *Phys. T. 38*) and (5 *Met. cap. 2. T. 3*): from universal causes universal effects proceed, and from particular causes particular effects emanate. Therefore if the second cause determines the first toward eliciting the former, so too toward the latter. I deny the major. To its proof I say that, even though God's concurrence is one and the same formally, it is nonetheless multiple virtually according to the multiplication of effects. Therefore it is diversely related to the acts of the second cause in species and in the individual, on account of the distinction I showed above. To the confirmation I say that Aristotle in that text does affirm that universal causes cause universal effects — as the sun causes sublunary effects both of living and of non-living things — and that particular causes attain particular effects — as this craftsman causes this artifact. But he says nothing about whether the second cause determines the first toward those effects or not. Therefore Aristotle's testimony does not harm us but helps us — especially according to Scotus's interpretation (*explaining it of universality in predicating, not in causing*), whom the Conimbricenses follow (*hoc loco cap. 7. quaest. 15. in fine art. 3*).

You will object second that an active power indifferent and undetermined by its very nature to opposite acts and effects is not determined by any agent — whether first or second. But the will of the second cause by its very nature is indifferent and undetermined to opposite acts — both in species (such as love or hatred) and in the individual (namely this love or this hatred). Otherwise its indifference, and freedom of specification and exercise — or of contrariety and contradiction — would be destroyed. Therefore the free second cause is not determined by the first as to the exercise of acts. Confirmation: given such a determination, the first cause would determine the second to evil and sin — and thus sin would not be attributed and imputed to the creature but to the creator, who would be determining the creature to that act which is evil or to which evil follows. I distinguish the major: by antecedent determination — I concede; by concomitant determination — I deny. To the distinction of the major I distinguish the minor. For the will, even if it is determined to one act, nevertheless has the power of eliciting the opposite act or suspending it. Therefore it remains entirely and fully free, as I showed at length in *Logic (l. 4. art. ult.)*. To the confirmation, the consequence is to be denied. For God determines the positive and physical act — not the absence and privation of the due rectitude of that act, which is its deformity or defect of the second cause, called the formal element of sin. Therefore sin is imputed not to God but to the creature — which, since it is bound to cooperate and act with God providing its concurrence, does not co-act but falls short — which is formally to sin, as can be seen abundantly in Scotus (*2 d. 37. quaest. vn. §. Ad solutionem. T. & V.*).

Question IV. On the Exemplar Cause.

The exemplar cause cannot be clear to us unless the idea is known to us — which seems to coincide with it. Therefore certain things about the idea itself must be discussed, so that the exemplar cause may be understood more plainly and clearly — especially because, as Augustine testifies (*4 Trin. alleg. à Scot. 1. d. 3. quaest. 4. sub R. §. Ad quaestionem igitur*), without ideas understood no one can be wise. Clement of Alexandria adds (*4 Strom.*): one who knows ideas leads a nearly divine life among men. This is indicated by Augustine (*lib. 83. qq. quaest. 46*).

Article I. Whether the Idea Is an Objective Concept.

Two more celebrated opinions shine out in this article. The first is that of Alexander (*1 p. quaest. 23. in 4. art. 1*) and his two chief disciples, Bonaventure (*1 d. 35. quaest. 1. art. 1*) and Thomas (*1 p. quaest. 15. art. 1*) — who hold that an idea is a formal concept. The second is defended by Scotus (*1 d. 35. quaest. vn. §. Ad ista*), Barg (*ibid.*), Bassi (*quaest. 2. art. 2*), Ockham (*quaest. 5*), and other Nominalists and Scotists — who teach that an idea is an objective concept.

Note first that the name "idea" has two etymologies. The prior is noted by Alexander (*2 p. suae summae adductae à Voirl. 1. d. 35. art. 1*): idea is derived from ἰδέω, which is the same as water. For just as through water diverse images of

things are represented and beheld, so through ideas various and diverse things to be made and formed by the intellectual craftsman are presented and offered to that craftsman. The later is given by Lodovico Vives (*in 7. lib. Ciuit. cap. 28*): idea derives its etymology from the Greek word which means the same as I know, I inspect, and I recognize. For one who is about to do something inspects the exemplar in the likeness of which he produces his work — as is clear of a painter who draws an image according to an exemplar proposed to him. And this is called idea, reason, form, species, and the like — of which at length in the Tract on the Knowledge of God (*disp. 4. q. 1*).

Note second, from Scotus (*4 d. 1. quaest. 4*), that something can be in the mind of an intellectual craftsman in two ways: subjectively or objectively. What is subjected to and inheres in the intellect is said to be in it subjectively — such as intellection, an intelligible species, and an intellectual habit. But what is presented and placed before the same intellect to be known and considered is said to be in that intellect objectively — such as a natural body and whatever other being is to be placed before it and understood. From this arises the division of concept into formal and objective. What resides in the intellect is called a formal concept; what is placed before it to be known and examined is called an objective concept. Now in the present it is called into doubt whether an idea is a formal or an objective concept.

Note third that the idea, taken generally, is defined as "an exemplar at which a craftsman looks as he works." "Exemplar" is placed as the genus. The remaining terms are added in place of the differentia. For in order that a craftsman may work rationally, it is necessary that he have an exemplar according to whose imitation he takes care to form and elaborate the artificial work intended by him. Now since a craftsman can look, whether within or outside his intellect, at a form in the likeness of which he intends to make his work, from this arises the division touched on by the Doctor (*4 d. 50. quaest. 3. §. Respondeo. C.*) into an internal exemplar — which is in the mind of the craftsman, as a house or health within — which is the idea of a house or health outside (*7 Met. cap. 7. T. 23*) — and an external exemplar, which is seen by the eyes, of which (*Exod. 25*): "Look, and make according to the exemplar that was shown to you on the mountain." Whether this twofold partition of exemplars is univocal or not, although philosophers do not seem to agree, they can be reconciled through the distinction of Scotus (*in fine prol.*) — who says it is not univocal with complete univocity, but is univocal with diminished univocity, as Aristotle touches on (*7 Met. T. 30*) and (*12 eiusdem, T. 13*), the explanation of which I gave in (*Epistle dialect. 1. 1. quaest. 1. art. 5. num. 17*). Furthermore, since some ideas are divine and others created, it can be doubted whether the aforesaid definition of idea is fitting to both or not. I think this is satisfied if we respond affirmatively. For although divine ideas are eternal, unchangeable, and the first forms in the likeness of which things are to be made ad extra — as the Doctor excellently pursues (*1 d. 35. quaest. vn.*) and Barg lucidly explains (*ibid.*) — they are

nonetheless true exemplars and objects known by the divine mind, in the likeness of which the divine will produces things in real being and existence, as Lyra aptly hints (*in expositione text. Ioan. 1*). And the aforesaid definition rightly applies to them; and what is subsequently attributed to them indicates the distinction that is drawn between them and created ideas.

The thesis is: an idea is not a formal but an objective concept. So Scotus (*max cit.*) in both works, and (*7 Met. in com. T. 23*). It is proved first from Aristotle (*passim nunc memorato*): "Health and a house outside the mind of the craftsman come from health and a house within the intellect of the same." From that text it is clear that it is not a formal concept, since the Philosopher there asserts that it is the what-it-is, in the likeness of which health and a house are truly constructed outside the intellect of the craftsman. Now this house is not rendered similar to the cognition that the craftsman possesses, but to that house placed before his mind — according to which he strives to produce it in the nature of things. Furthermore, Aristotle both here and elsewhere argues against Plato — not because he teaches that ideas are the quiddities, species, and characters of things, for Aristotle himself does not deny this — but because Plato posits them really severed and separated from individuals and singulars, as I showed at length in Logic (*l. 2. quaest. 1. art. 3.*). Therefore in the Peripatetic school, an idea is not a formal but an objective concept. St. Augustine agrees (*1. 83. qq. q. 26*) — who, following Plato, places ideas in the divine intelligence containing them: but intelligence and cognition or intellection coincide with the formal concept, while what contains is not what is contained. If therefore according to Augustine the formal concept or intelligence of God contains ideas, it is plainly established that in his view an idea is not a formal but an objective concept. All the more so since the same saint adds there that man was made according to one idea or reason, and a horse according to another. But there is only one formal concept or one most simple intellection of God; while there are multiple ideas according to the plurality of things to be made. Therefore an idea is not a formal but an objective concept. The same thing Dionysius (*de divinis nominibus, cap. 5*), Seneca (*1. 3. Epist. epist. prima ad Lucil.*), and Gerson (*1 de vita spirituali, lect. 1. corol. 12*) seem to maintain. Second: that to which the definition of an idea applies is an idea, as is clear from the locus from definition to what is defined. But the definition of an idea fits an objective concept and not a formal one. For the former — and not the latter — is what a craftsman intends and proposes to himself to be imitated: as a physician intends to introduce health into the patient according to the health he carries in his mind — which is health as known by him, not however his cognition of it. Third: an idea is an image and exemplar of a thing to be made, at which a craftsman looks while intending to produce in the nature of things something similar to it. But a formal concept is that through which — not that which — a craftsman looks: just as vision is that through which the seeing person sees, not that which he sees. Fourth: an external exemplar is undoubtedly not a formal concept — as is plainly clear of

an external image in the likeness of which a painter strives to draw and form something. Therefore the same must be maintained of the internal exemplar, which I showed in the third note to agree univocally with the external.

Furthermore: what is presupposed for producing something is not that which presupposes it — as is clear of a whole that presupposes its parts, which are not the whole itself but are pre-required for making the whole. But a formal concept is presupposed for an idea. For in order that a craftsman may know what is to be made not ignorantly but rationally, it is necessary that he first know it; therefore it is not an idea. Moreover: a name signifies what its inventor instituted and decided to signify. But the inventor of the name "idea" was Plato — as Augustine (*precit.*) attests — who through ideas designated the things themselves, saying that the idea of man is man himself, and the idea of a horse is the horse itself, and so for other things and specific natures. Finally, St. Paul supports this (*Hebr. 11*): "By faith we understand that the world was framed by the word of God, that from invisible things visible things might be made." Where the Literal Doctor adds that the saints place ideas in the divine mind — which are invisible forms from which all visible things proceed, just as visible artifacts come from an invisible exemplar that is in the mind of craftsmen. From all these it is clearly established that an idea is an objective concept that a craftsman proposes to himself to be imitated for the efficiency of the work intended by him.

You will object first, from (*7 Met. T. 23*): an idea is a form. But form pertains to the formal concept and not to the objective one; therefore an idea is a formal concept. I reply that Aristotle and other authors who call an idea a form are to be interpreted — not of a form that informs, which pertains to a formal concept — but of a representative and objective form, in the likeness of which a craftsman renders his work, as is clear from the text's examples of health and a house in the mind of the craftsman, in the likeness of which it is constructed outside by the craftsman himself.

You will object second that an idea is an exemplar expressive and declarative of a thing. But to express and declare is of a formal and not of an objective concept; therefore an idea is a formal concept. I distinguish the major: presuppositively — I concede; formally — I deny. In this way ideas are also called predestinations and good wills by St. Dionysius (*cap. 5.*). And by Augustine: eternal, unchangeable, and beatific reasons, and the life of the craftsman.

You will object third: an idea is either something distinct from the thing to be made or is the very thing to be made — since between the identical and the diverse nothing mediates (*10 Met. T. 12*). But an idea is not distinct from the thing to be made — since very often a craftsman works with no idea pre-existing in his mind. Nor does it coincide with it — otherwise the same thing would be the cause of itself, which is false and absurd. I concede the major. To the minor I say with Bassi (*cit.*) that the idea is the same thing to be made — not in the same

but in a different mode: namely, the thing in intentional and ideal being is the cause of itself in real being. Just as the final cause in intention is the cause of itself in execution — as the Philosopher hints (*paulò ante cit.*) and Scotus (*ibid.*).

Article II. What the Exemplar Cause Is and to Which Genus of Cause It Is Reduced.

The first thesis is: the exemplar cause is rightly defined as that which influences the exemplated thing with respect to objective being, which a craftsman holds in his mind in the likeness of which he produces the exemplated thing ad extra. This is in agreement with the Doctor (*1 d. 2. quaest. 2. §. Ad 1. quest.*) and (*dist. 36. quaest. 1. §. contra ista*) and (*1 Rep. d. 2. quaest. 1*), and is deduced from Aristotle (*7 Met. 30. 12. eiusdem, 8*). It is proved by an easy and common middle: that is aptly and fittingly defined which consists of genus and differentia, as I often repeated. But the aforesaid cause obtains a genus and differentia, as is clear to one who runs through the individual terms mentioned. And it contains nothing superfluous or deficient, as can be seen from those same terms; therefore it is well defined.

The second thesis is: the exemplar cause is a real and physical cause. Aristotle and Scotus (*in praeunte aff. cit.*) do not decline from this. It can be urged first from the final cause — which I will show in its proper place to be a true and proper physical cause. And those who hold the opposite do not deny that the same must be maintained of the exemplar cause — by name Fuente (*2 Phys. quaest. 8. diff. 3. art. 1*). Then: that on which an effect really depends in being is a proper and physical cause, as is clear from the definition of cause taken universally. But an artificial effect truly and physically depends on an exemplar cause: for a craftsman fabricates a work in the likeness of the image he has in his mind. Hence St. Augustine writes (*tract. 1. in Ioan.*): "A craftsman makes a chest. First he has the chest in his art. If he did not have it in his art, how could he produce it by fabrication? But the chest is so in the art that it is not that very chest seen by the eyes." He holds the same (*ibid. Tract. 2*). Moreover: that is a true and physical cause of something in consequence of whose being another follows, as the Doctor notes (*in com. 4. Met. T. 3*) and (*1 eiusdem T. 1*). But from the exemplar cause there follows another — namely the exemplated thing — as is plainly seen in those who perform their artificial works in the likeness of their exemplars. Therefore the exemplar cause is established as a true, real cause.

The third thesis is: the exemplar cause is reduced to the efficient cause. So Scotus (*ubi supra*) and (*1 dist. 35. quaest. 1*), and it is deduced from Aristotle (*2 Phys. T. 33*) and (*7 Met. T. 30. 9. eiusdem T. 3*), against the Complutenses (*2 Phys. disp. 9. quaest. 5*), Conimbricenses (*ibid. cap. 3. quaest. 5. art. 1*), and Alb (*1 distinct. 20. art. 1*). It is proved first from Dionysius (*4 de divinis nom.*) and Augustine (*12 Ciuit. cap. 25*) — who affirm that ideas are the efficient causes of existing things. Second: as a natural form stands with respect to its natural effects to be produced, so an ideal and artificial cause stands with respect to artificial works. But a natural

form is the efficient cause of its effects, as is clear of the rational soul and other natural forms; therefore the same must be maintained of the artificial form, which is the ideal and exemplar cause. Furthermore: the efficient cause is subdivided into the natural — which operates without ideas — and the intellectual — which requires ideas, according to which it produces its works. Again: the exemplar cause does not pertain to the material cause — inasmuch as it is found in those devoid of matter, such as an angel and God. Nor to the formal cause — which imports imperfection, namely information and being a part of a composite: but the exemplar cause, since it belongs to God, involves no imperfection per se. Nor to the final cause — since the final cause is nobler than those which are for the sake of the end, while many exemplars are less noble than the exemplated things, and the exemplated thing does not depend on the exemplar as on its end, since the exemplar tends toward the exemplated thing as toward its terminus. Therefore it remains that the exemplar cause is reduced to the efficient cause.

You will object first that ideas, by their etymology, are the same as form, as Augustine notes (*lib. 83. qq. quaest. 16.*). Therefore the exemplar cause is reduced to the formal cause. Hence Aristotle (*2 Phys. 28*) and elsewhere seems to place it in the genus of formal cause. I reply that an idea has such a denomination not by reason of an informing principle — since it is in God, from whom all information is far removed — but by reason of an effective principle: for form is the principle and origin of operations. Thus Augustine and Aristotle (*cit.*) are to be explained.

You will object second that an idea is an exemplar that gives — as a craftsman looks at it — the formal and specific being of the thing: but to give back formal and specific being to a thing pertains to the formal cause. Therefore an idea is reduced to the formal cause. I concede the prior part of the major but deny its later part, as is clear of the divine ideas, which are efficient — not formal — causes. Wherefore if an idea has something in common with form, it pertains not to the formal but to the effective principle.

Question V. On the Instrumental Cause.

Single Article. Whether an Instrument is Active.

Fuentes (*2 Phys. quest. 6. diff. 2.*), Poncius (*quest. 8.*), and Mastrius (*ibidem, quest. 5.*) gather together many things concerning the instrument, but since not a few of these are theological, and others are more conveniently examined elsewhere, I shall in this place only state and decide the proposed difficulty.

Note, from Scotus (*4. distinct. 1. quest. 1. §. Ad quaest. ergo. DD. Et quest. 5. §. Ad primam ergo. F. Et distinct. 6. quest. 5. §. Ad istam quaest. E.*) and Suarez (*disp. 17. Met. sect. 2. num. 7.*), that instrument is an equivocal term and admits of four acceptations. First, it is taken for a secondary cause as distinguished from the

first cause, in which sense God is said to act through secondary causes as his instruments, as Damascus notes above all others in his Physics, cap. 9. In this sense the first cause alone is principal, because it alone is independent. Second, it is taken for a part of a living body; in this sense Aristotle (2. *anima* T. 16.) calls the organs of the senses, or the sensitive powers, instruments by which the soul exercises its vital operations. Third, it is taken for some prior quality that disposes and prepares a subject for the introduction of a form into it; in this sense the heat of fire is called its instrument, because through it the wood is disposed to receive the form of fire. Fourth, it is taken for that which an artisan uses to perform the works proper to his art; in this sense the term derives its etymology from art, according to Scotus (2. *Reportat. distinct. 1. quest. 1. §. Item hoc vocabulum.*), and in other places previously cited. For an instrument, properly speaking, is that which is moved by an artisan to produce an artificial work, as a saw, a chisel, and things of this kind; and it is about this that the principal difficulty arises. Hence Mayr (4. *dist. 6. quest. 2.*) aptly distinguishes instrument into: artificial, which is properly called an instrument; natural, which is less properly called an instrument, such as the heat of fire; moral, which is called an instrument in a broad sense, such as a habit; and supernatural, as the sacraments are called instruments of grace and the fire of hell an instrument of divine justice. Further, into separated, as shed seed, and conjoined, as the cold of water.

Third assertion: an instrument properly so called is not active. The Doctor holds this (*ubi supra*) and (*Theor. 17.*). It is established first: the first act is presupposed to the second act, because the second proceeds from the first; but an instrument does not of itself possess a first act, that is, a pure power and capacity for acting, as is evident from a saw, which when placed in the corner of a house does nothing of itself unless it is pre-moved by an artisan to cut something; therefore an instrument is not properly active. Second, an instrument as instrument has nothing but shape and hardness; but these belong to the genus of passives. For shape is either quantity or relation, being a certain order of parts in a whole; and neither quantity nor relation is active. Nor is hardness, because it is resistive, not active.

You will object first: what is comprehended under the genus of efficient cause is active; but an instrument is contained in the category of effecting cause, which is divided into principal cause and instrumental cause, as is evident (*quest. 2. art. 1. huius lib.*); therefore an instrument is active. I respond by conceding the major; to the minor I say that an instrument is active, not of itself, but through the actual motion and influx of the principal cause. For this reason it is reduced to the genus of efficient cause, as Scotus writes (4. *dist. 12. quest. 3. §. Dico ergo D.*) following Aristotle (5. *Met. cap. 2. & 1. Phys. T. 31.*).

You will object second: natural instruments are active, as is evident from seed, which is the cause of generation. Likewise supernatural instruments, as the sacraments, are productive of grace; therefore the same must be asserted of

artificial instruments. The consequence is to be denied, for the reasons given above in the assertion, and especially because natural instruments act only dispositively and do not reach the term of the principal agent. And the sacraments are said to be productive of grace not physically but morally, according to Scotus (*4. distinctione 1. quaestione 4. §. I.*).

Question VI. On the Material Cause.

Single Article. What the Material Cause is and What it Causes.

The material cause is defined by Aristotle (*2. Phys. T. 28. 5. Met. T. 2.*) and Scotus (*ibid. in com. & Theor. 20.*) as that from which something comes to be when it is present therein, as a statue from bronze and a bowl from silver. In this definition the word "principle" is understood as the genus, and the remaining words are added so as to distinguish the material cause from the other causes. Most importantly, the phrase "when it is present therein" is added on account of privation, which departs with the advent of form; the material cause, however, remains together with the form, since it is its subject and an intrinsic part of the whole, just as bronze remains when a statue is made from it, and silver when a bowl is fashioned from it. I shall show in the following assertions what the functions and effects of matter are.

First assertion: the material cause sustains the form. This is derived from the Doctor (*2. distinct. 12. quest. 1. 2.*). It is proved first from Aristotle (*1. Phys. T. 70.*): matter is the common subject of contrary principles, which are privation and form; and when privation is absent from matter, form is present in it and persists in it so long as the composite of both persists. Second: every subject sustains that which is in the subject, as is evident from the subject of accidents; but the material cause is the subject of form, as the Philosopher writes (*1. Phys. T. 82.*), where matter is defined as the subject of all forms; therefore the material cause serves as the support of form.

Second assertion: the material cause exercises its proper influx upon the composite, though a partial and modest one. The Doctor holds this (*ubi supra*). The first part: every cause causes something, as is clear from the definition of cause, which is a principle essentially inflowing into an effect; but the material cause is truly a cause. For it is numbered among the four genera of causes; therefore it has a proper influx and causality with respect to the composite. Second: the composite is something produced and intrinsically caused by intrinsic causes, which are matter and form, as I showed (*lib. 2. quaest. 6. art. 2.*); but it cannot be totally and intrinsically caused by form alone, since it is a third thing coalescing from two parts; therefore it is partially caused by matter. Furthermore, the material cause is defined as that from which something comes to be, as stated at the beginning of this article; but the composite is made from matter as from a part — for from wood as from matter, fire produces fire by the

agency of fire — therefore the material cause exercises its partial causality with respect to the composite.

The second part is established thus: the quality of a thing's power and capacity is proportional to the quality of its entity, since power flows from entity and follows upon it; but the entity of matter is partial, imperfect, and modest, since it is the lowest of beings, as has been said; therefore its influx and causality are partial, slight, and attenuated. Whether, however, the union and eduction of form are effects of the material cause, the Moderns investigate at length. For my part, I think it sufficient to say that neither is its effect. For union is a relation, which is not produced but co-produced, arising from the positing of its terms; and form is not properly made but is educed or introduced into matter, and only the composite is properly made, as I showed abundantly (*1. 2. quaest. 1. art. 1. in responsione 1. oppositionis*).

You will object: it seems improbable and incredible that matter, so imperfect and lowly, should concur in producing so many composites remarkable in number and dignity, such as the celestial and sublunar bodies; therefore it behaves toward them only passively. I deny the antecedent; for experience demonstrates that from the smallest seed a great tree is produced, and from small grains plants, herbs, and other things of no small size are produced. Thus the power of God shines forth the more clearly in granting to matter, the lowest of beings, the capacity to partially cause so many composites.

Question VII. On the Formal Cause.

Article I. What the Formal Cause is and What it Causes.

The formal cause is defined as that through which something comes to be when it is present therein. This definition is easily understood from the definition of the material cause given in the preceding question. The words "through which" are merely added so as to differ from the other causes. For the formal cause is that through which a thing receives its specific being. And just as the material cause performs a twofold function, so likewise does the formal cause: it informs matter and partially causes the composite.

First assertion: the formal cause informs matter. This is handed down by Aristotle and Scotus in the place cited in the preceding question, assertion I, and is proved thus: form is the act that perfects and determines matter, as has been said (*1. 2. quaest. 4.*); therefore the formal cause informs matter, which is indifferent, indeterminate, informable, and perfectible.

Second assertion: the formal cause has a proper partial causality with respect to the composite. The Doctor holds this together with Aristotle (*ubi supra.*). It is established first: the formal cause is placed among the four genera of causes, as was asserted in this book (*quaest. 1. art. 2.*); therefore it obtains a proper causality distinct from the rest. Second: that through which something comes to be has a

proper causality, because causality bears upon its effect; but through the formal cause the composite is partially produced in a principal manner, as is clear from its definition given at the very beginning of this article. Again, the formal cause provides the intrinsic and essential being of a thing, in accordance with that oft-repeated saying, form gives being to a thing; but it cannot give being to a thing unless it participates in a proper causality, just as an agent without action cannot act. Furthermore, the composite is the effect of matter and form, because it is made of act and potency (2. *animae* T. 7. Et 8. *Met.* 15.); but by act is understood the formal cause; therefore the formal cause possesses a peculiar and principal influx and causality with respect to the composite.

You will object first: form confers no being upon matter, since matter has its own essence and existence independent of form, given that it can exist without form, as I taught (*l.* 2. *quaest.* 2. *art.* 8.); therefore the formal cause causes nothing whatever in matter. I distinguish the antecedent: form does not provide matter with entitative being — this I concede; with specific and perfective being — this I deny. For matter itself is determined and specified through form. One may also say that matter does not borrow intrinsic but only extrinsic being from form.

You will object second: if the formal cause were to inform matter and cause the composite, it would be a twofold cause, because it would produce a twofold effect; but it cannot be a twofold cause, as is known to all; therefore it does not inform matter nor cause the composite. The major consequence is to be denied. For it is one cause having a twofold manner of causing, just as light possesses a twofold power of causing, namely illuminating and heating.

Article II. Whether God can Supply the Causality of the Material and Formal Causes.

There is the opinion of Fonseca (5. *Met.* cap. 2. *quest.* 8. *sect.* 4. *quest.* 12. *sect.* 2.), who holds that God can supply the place of the causalities of the material and formal causes. Against him stand Scotus (1. *d.* 5. *quest.* 2. §. *contra istam.* C. Et d. 8. *quest.* 4. §. *contra istam solutionem* X.), Lychetus, Bargius (*ibid.*), Fuentes (2. *Phys.* *diff.* 5. *art.* 1.), Mastrius (*disp.* 5. *quest.* 5.), and others who commonly deny that God can exercise the causalities of the said causes.

Note that this difficulty can be treated in two ways: in its proper genus, that is, whether God can perform the functions of these causes with respect to their own proper and genuine causalities; or in a different genus, for example in the genus of efficient cause or final cause, which are without doubt attributed to God. Likewise the controversy can be about their mutual causalities. For matter sustains form and form is educed from its potency; and form informs matter and gives it specific being. Or the controversy can be about the causality with respect to the composite, for both concur in causing and constituting the composite, since they are its intrinsic and essential principles and parts.

First assertion: God cannot discharge the functions that the material and formal causes perform for one another. This is consistent with the Doctor (*ubi supra*). And (4. *distinct. 12. quest. 1. §. Ad quaest. E.*). It is proved first: God is a perfect cause causing perfectly, since he is an infinite ocean of perfections, as has been said (*tract. 2. Summa theologiae, disp. 2.*); but the material and formal causes are imperfect causes causing imperfectly. For the one is subjected to the other, and the former is perfected and actuated by the latter; therefore God cannot exercise their causalities. Second: God is neither referred nor ordered to another, since he is infinite, absolute, the terminus and end of all things; but the aforesaid causes are mutually referable: each in turn is ordered to the other, as the imperfect to the perfect, and potency to act. Third: matter and form are united to each other so as to cause the composite and to persist in it as its intrinsic and constitutive parts; but it is incompatible with the divine nature for God to belong to the essence and quiddity of the composite, as is evident; therefore it is equally repugnant for him to exercise the causalities of the said causes.

Second assertion: nor can God supply the causality of matter and form with respect to the composite. This is in conformity with Scotus in the places cited above. It is proved first: matter and form cause the composite in such a way that they entirely enter into its essence and become its essential parts, as is clear from the soul and body in a human being; but God cannot be the essence, nor belong to the essence, nor be an essential part of a composite, since otherwise he would be imperfect, given that a part is imperfect and the whole is more perfect than it. Second: a part is ordered to the whole so as to integrate, constitute, and complete it, as is evident from the parts of the human body; but God cannot be ordered to another, nor composed with another, since he is most simple, as I asserted in the passage just cited. Third: matter and form so constitute the composite that this composite depends upon them intrinsically and essentially, to such a degree that it cannot exist without them, as a human being cannot exist without soul and body; but this is repugnant to God, from whom every imperfection is infinitely distant; therefore no causality of theirs can be supplied by him, the conclusion being reached by Scotus (1. d. 2. q. 2. §. *Quantum ante M.*).

Third assertion: in the genus of efficient cause, God can exercise the causalities of the aforesaid causes. This is derived from the Doctor in the fourth place recalled above. It is proved first: every created being depends upon God in its becoming and in its being, since God alone is independent and self-subsistent; but the causalities of the aforesaid causes are within the series of created things and in their proper genus cannot be administered by God, as was proved in the preceding assertions; therefore they fall under the genus of efficient cause, which together with the final cause belongs to God, as the Doctor argues in the first passage just cited. Second: in the Blessed Eucharist God sustains accidents without a subject, just as a subject would supply if it were present, setting aside

every trace of imperfection, as the scholastics teach as a matter of faith (4. d. 10.). Such sustentation and conservation is reduced to the genus of efficient cause; therefore the same is to be asserted of the aforementioned causalities of matter and form, with Scotus concurring (1. d. 5. q. 2. §. *contra istam C.*).

You will object first, from Philippians II: the Deity is said to be the form of God; and in the same place the humanity of Christ our Lord is called the form of a servant; therefore if form is attributed to God, surely also its causality. Hence God is said to be formally wise and formally just, on account of the wisdom and justice he truly possesses and holds. I respond that these and similar expressions are said of God not properly but metaphorically, as Saint Dionysius signifies (*l. de divinis nom. cap. 8. & inde*). For just as form gives being to a thing and vivifies it, so God provides being and life to all things. When, however, it is objected that God is called formally wise and just, what is meant is that attributes of this kind truly and really belong to God himself.

You will object second: nothing can be caused by a secondary cause unless the first cause concurs therein, as was sufficiently shown above; but the composite is caused by matter and form, which, according to Scotus, really differ from the composite; therefore God exercises the causalities of these causes. I respond that the major is to be taken of efficient and final cause, not of the others, on account of the imperfection they carry with them and the repugnance demonstrated above. If there is any concurrence of God in them, it is reduced to the effecting cause.

You will object third: God can perform the causalities of the material and formal causes without any imperfection; therefore there is no repugnance. The antecedent is proved: God can conserve without form and conversely, and likewise sustain a nature without its own personal subsistence, as he did in the hypostatic union of the divine Word with the humanity assumed by him. I deny the antecedent; to the proof I say it is reduced to efficient cause. To the other point that is added, I say that it is a mere personal termination, which I showed at length (*tract. de incar.*) to involve no imperfection and no peculiar causality.

Question VIII. On the Final Cause.

The final cause is defined by Aristotle (2. *Physic. T. 29. 31.*) as that for the sake of which something comes to be. Aristotle held it in such high regard, both in the place just cited, cap. 8, and in (1. *de partibus animalium, cap. 1.*), that ignorance of it caused the ancient Philosophers to fall into many errors. Therefore, so that we may not succumb to any error, we must examine it, presupposing all that we treated of it at length in the Moral Philosophy (1. 2. q. 5.).

Article I. Whether the End is a True Real Cause.

Hurtado (*disp. 13. de anima sect. 5.*), Cavellius (*ibid. disp. 1. sect. 19.*), Fuentes (2. *Phys. quaest. 7. dif. 2.*), and Mastrius (*disp. 7. quaest. 8. art. 5.*) deny that the end is a

true physical cause and say it is a moral cause. But Scotus (*1. Met. in com. cap. 2. Et l. de primo principio cap. 2. Et 5. Met. quaest. 1.*), Antonius Andreas (*ibid. quaest. 2.*), Trombetta, the Complutenses (*2. Phys. disp. 14. q. 2.*), Suarez (*disp. 23. Met. sect. 2.*), and the others commonly affirm that the end is a true and real cause.

Note that this dispute is more a matter of words than of substance, and consists in the interpretation of real being and intentional being. Here a real being is one that has existence outside the intellect, as the heat of fire is a real being. An intentional being is one that has existence in the intellect; but existence in the intellect can occur in two ways: subjectively, as knowledge inheres in the mind and is a real being; or objectively, and this again in two ways: one way objectively, as an object to be known is presented and set before the intellect, and this too is a real being, for example a stone presented to the mind; the other way purely objectively, which is only presented to the intellect and is made by the intellect, and this is a being of reason distinct from a real being, as I showed (*in Log. l. 1. quest. 3. art. 5. & latius in Met. l. 5. quaest. 1. art. 2.*).

Assertion: the end is a true and real cause. The Doctor holds this in the places surveyed above, and Aristotle implies it (*2. Phys. c. 3. T. 29. 5. Met. c. 2.*), placing the end in the series of the other real causes. It is proved first: the definition of a real physical cause applies to the end, for the end is a principle essentially inflowing into an effect, since it moves the agent to act for the sake of its execution and possession; therefore the end is a real physical cause. Second: a real effect is caused by a real cause, for a real being is not made by a being of reason; but the effect of the end is real, such as health caused by a physician in a sick person, and happiness acquired and possessed by a blessed person. Third: cause, taken generically, is univocal with the four kinds enumerated, among which is the end; for its definition applies univocally to all of them and is predicated equally of each. Furthermore, the end is studied expressly in Physics and Metaphysics, which are real sciences. Finally, a real effect depends essentially upon the end: for just as an effect comes from an efficient cause as from a real cause, so on account of the end, for whose sake the effect is produced, such a real effect is obtained; and therefore the end is established as a true and real cause. This is clearly indicated by Saint Augustine (*quarto contra Iulianum cap. 3. Et contra Adversarium legis.*). For the end is that for whose sake everything is done that is done in any manner of service. For between service and end there is this difference: service is in those things we ought to do, while the end is that for the sake of which we do them.

You will object first: Aristotle (*1. de gener. T. 55.*) writes that efficient cause is the true cause, whereas the end is a transferred and metaphorical cause; therefore in the Peripatetic school the end is not a true and real cause. I respond that Aristotle is to be interpreted not absolutely but relatively. For the efficient cause is called every cause by antonomasia, as I observed from Augustine (*quaest. prima huius lib. artic. 2.*), because it has the most evident manner of causing and a more

real influx. Hence the final cause, in comparison with it, is called transferred and its influx metaphorical, though in truth it is a real and genuine influx, albeit intentional and of the soul, by reason of which an animal is moved to attain it, as I declared above.

You will object second: what does not really exist in act is not a real cause in act; but the end does not really exist in act; therefore the end is not a real cause in act. The major is evident, for a cause in act has its effect in act (*2. Physic. 28.*). The minor is at hand: health does not yet exist, but walking, which is its cause, does exist. I concede the major; I distinguish the minor: as regards intention, I deny it; as regards execution, I concede it.

You will press further: an intentional being cannot be the cause of a real being; therefore if the end is in intention, it cannot cause a thing in execution, which is a real being. I deny the antecedent. For the house within, which is an intentional being, is the cause of the house without, which is a real being (*7. Met. T. 23.*). So if the exemplary cause, which is intentional, truly and really inflows into its effect, why will this be denied to the end?

You will object third: a cause is a principle, as is clear from its definition; but the end is not a principle, because end and principle are opposed to one another, since a principle is that from which a thing begins and an end is that at which it terminates. I respond through the same distinction: the major being conceded, I distinguish the minor — as regards intention, I deny it; as regards execution, I concede it. Therefore a principle is not opposed to an end in intention but only in execution.

You will say: cause and effect are mutually related, since they are correlatives (*5. Met. 20.*); but the end is not so related, because it does not exist; therefore it is not a true real cause. I concede the major. To the minor I say that even if the end does not exist externally, it nonetheless exists internally, which does not remove its true reality and existence, as is apparent by analogy with the exemplary cause, which, though it is in the mind of the artisan, yet truly exists and truly and really inflows into its effect, with cause and effect mutually related.

Article II. Whether the End Causes according to Intentional Being or according to Real Being.

Philosophers seem in this present question to be disputing more about manner of speaking than about substance, just as in the preceding article. Some, such as Ockham (*2. quaest. 3. art. 2.*), Gabriel (*ibid. distinct. 1. quaest. 5. artic. 2.*), Toledo (*2. Physic. quest 14.*), and the Conimbricenses (*cap. 7. quaest. 23.*) judge that the end causes according to the real being it has from the side of things and outside the mind of the artisan. Others, such as Trombetta (*5. Met. quaest. 1.*), Poncius (*ibid. quaest. 3.*), and Capreolus (*d. 25. quaest. 1. secundi*), hold that the end causes

according to the intentional being that the artisan and intellectual agent carry in mind.

Note first that corresponding to the twofold positive and objective real being that a thing can possess, there is a twofold existence — positive real and objective real — and a twofold real action: one that proceeds from the positive real, as heating from fire, and one intentional that flows from the objective being existing in the mind of the agent, of which Aristotle makes mention (7. *Metaphysica*, T. 23.) when he says that the external house is made from the internal house, meaning that the house existing in reality is made from the house existing ideally in the intellect of the builder. Now the question is whether the end exercises its causality insofar as it exists objectively and intentionally in the intellect of the agent, or insofar as it exists from the side of things positively and really.

Note second that in any cause three things can occur: the principle which, for example fire; the principle by which, that is, the heat by which fire heats; and the approximation, which is the condition without which fire cannot heat the heatable object. The present question is whether the principle by which in the final cause is intentional being or real being, or merely a condition without which the end would not finalize. When intentional being is spoken of, this does not mean merely known or apprehended being, for that, being a being of reason, cannot cause a real being; rather, it means a real being objectively conceived, whether or not it exists from the side of things, provided it can exist — as when someone labors for the acquisition of virtue which he does not actually have but can have and possess, it exists objectively in him, toward the acquiring of which he is moved and by whose desire and love he is drawn. Accordingly, the mere fact of being known or apprehended is not the formal reason for causing but is only presupposed so that the will, which is not borne toward what is unknown, may be able to act and to acquire and enjoy the end proposed to itself in the prior light of the intellect.

Assertion: the end causes not according to real being but according to intentional being. This is derived from the Doctor (*quaest. 4. prol. §. contra istam. 4. d. 49. quest. 8. §. secundo videndum. 5. Met. quest. 1. antè §. Ad quaest. Et 1. post quaest. 57. §. Ad 1. arg.*), where these words are read: "It is not necessary for the cause to precede the effect really, but it suffices that the thing precede the effect in intention; yet this intention of the end is not the cause with respect to the effect, but the thing itself of the end under intention, and this suffices for it to cause the effect really." It is proved first: the cause is prior to the effect, as I showed (*quest. 1. art. 4. huius lib.*); but the end according to real being is not prior to the effect but posterior to it, whereas according to intentional being it is prior to the effect. Hence that celebrated saying of Scotus (*1. Rep. d. 41. quaest. vn. §. Dices ex 7. Met. T. 7.*): what are prior in intention are posterior in execution; therefore the end is a cause according to intentional being. Second: the end

causes through that by reason of which the agent is moved to act, as is clear from the definition of the end; but the agent is moved to act on account of intentional being. For the end moves under the aspect of the lovable and the desirable; but to be lovable and desirable as apprehended by the intellect is an intentional being; therefore, etc. Third: the same thing cannot be both cause and effect with respect to the same thing and in the same genus of cause; but the end according to real being is an effect; therefore it cannot be a cause unless according to intentional being. The major is evident. The minor is clear: for the end in real being is the terminus of the agent's action and the completion of the thing; therefore the end is a cause not in real but in intentional being. Finally, more often than not the end does not exist in real being, as I observed above, and yet the agent intends it and is moved to act for the sake of its attainment. I add that sometimes the end is merely apparent, and sometimes impossible, as is evident from Lucifer desiring equality with God, which is impossible.

You will object first: from Aristotle (*2. Phys. cap. 3.*), the end has the character of the best, toward which perhaps the author of Ecclesiasticus looks (*cap. 7.*) when he says: "The end is better than the beginning." But this does not apply to the end in intentional being, therefore it applies to real being. I respond that the major is to be interpreted of the end taken as completion and in real being, not of the end as cause and in intentional being. Hence the argument does not harm us but profits us.

You will object second: the end moves the agent to act, for the agent is allured by its desire and love to pursue it; and once it is attained, the agent's action ceases, as Aristotle writes (*1. de gen. 55.*). But it is a real cause, as has been said in the preceding article; therefore it moves according to real being. I respond that its motion is intentional and metaphorical, as Aristotle says in the passage just cited. And it is a real cause because not the intention but the thing under intention moves the agent to act, according to Scotus in the passage cited above.

You will ask first: whether the end is the first of all causes? I respond affirmatively, together with Aristotle (*2. Phys. T. 31. Et 12. Met. T. 36.*) and Scotus (*tract. de primo principio, cap. 2. concl. 4.*). It is established first: that which is first intended by an intellectual agent is primary; but the end is first intended by an intellectual agent, for in intention the end is prior to the things that are ordered to it. Hence a person first proposes beatitude to himself, and then devotes effort to the opportune and necessary means for attaining it. Second: that which moves another to act is prior to that which is moved; for a mover as mover is prior to the thing moved, just as a cause is prior to its effect; but the end moves the agent to act, since the agent operates for the sake of the end; after which the efficient cause unites matter and form, which cause the composite; and so the end is found to be the first in the order of causes.

You will ask second: whether the end is nobler than the other causes? I respond affirmatively, together with Aristotle in the places cited and Scotus (*ubi supra*

concl. 5.), both because the end is a mover and is not moved, as I said above, and as the Doctor notes (*quest. 4. prol. Et 1. distinct. 1. quaest. 3. §. Ad argumenta*), and also because the agent operates for the sake of the end. Hence the Commentator rightly adds (*5. Met. in com. cap. 2.*): "Completion, liberality, and goodness are not found in things except on account of the final cause; and therefore what lacks a final cause lacks all good."

Article III. Which Things Act for the Sake of an End.

This doubt can be raised about many things: God, Angel, man, brute animal, and those things constituted by nature alone. Among these, the greatest difficulty concerns the brute animal, concerning which various opinions are rehearsed by Toledo (*1. Phys. quest. 12.*). What is to be said by us in accordance with truth and with Scotus, we shall disclose through the following considerations.

Note first that some animate beings lack memory but are endowed with imagination or the estimative power, by which they seek what is suitable for them and reject what is unsuitable, and these are borne only toward present objects; while others possess memory, by which not only present but also future things are foreseen, as is evident from ants gathering grains of wheat and birds building nests, in which a certain species of prudence shines forth, as Aristotle notes (*1. Met. cap. 1.*) and Scotus (*ibid. quaest. 3.*).

Note second that there is a threefold order and degree of those that tend toward an end. The first is of those that not only apprehend the end under the aspect of the good and the suitable, but also know the relationship and proportion of sufficient means to obtain it, and these act from deliberate choice and spontaneously, such as the Angel and the human being. The second is of those that indeed perceive the end under the aspect of the suitable, but do not discern the means, nor compare them with one another as to whether they are apt, suitable, and sufficient to attain it, but are naturally carried toward it by the motion of imagination or the estimative power, such as brute animals, which are said to be driven toward an end rather than to act (*2. Phys. T. 59.*). The third is of those that do not recognize the end at all, being devoid of sense and intellect, which tend toward it naturally or by natural inclination, as a heavy body tends downward, for example a stone seeks the center.

Note third that every thing has its end (*2. Phys. cap. 8. T. 51.*), to such a degree that particular causes tend toward a particular end, as the lion toward the generation of the lion; while universal causes tend toward a universal end, as the heavens toward the everlasting production and conservation of sublunar things in species and in genus. Among these, moreover, some are proximate ends, some remote, others intermediate, and still others ultimate, of which I treated abundantly (*lib. 1. Philosophiae moralis, quaest. 3. art. 1.*).

First assertion: God acts for the sake of an end, not with respect to himself but with respect to others outside himself. This assertion is twofold, as the Doctor presents it (*1. dist. 1. quaest. 5. §. Ad argumenta*). The first part is proved first: what has no efficient cause of itself has no final cause for the sake of which it is roused to action, because the causality of the end is to move the agent to act metaphorically. But God has no efficient cause of himself, since he is non-effectable and non-causable, as the Doctor demonstrates (*cit. dist. 2. quest. 2. §. Quantum ad 1. H. & inde*). Second: in God, one thing is not for the sake of another, nor is one ordered to another, since all things are infinite and supremely perfect, formally or really; therefore with respect to the divine predicates and attributes, God does not act for the sake of an end. The second part is proved first from Sacred Scripture: "The Lord has made all things for his own sake" (*Prov. 16.*); and "I am the alpha and the omega, the beginning and the end" (*Apoc. 1.*), where Lyran adds: "God is the beginning of all effects and the end to which all things are ordered." Second: God does many things for the sake of the elect, as is evident from (*1. Cor. 13.*): "All things are yours, and you are Christ's, and Christ is God's." Hence Augustine subjoins (*lib. 83. qq. quaest. 56. & lib. de spiritu & anima, cap. 42.*): "Man consists of body and soul, and whatever is seen with bodily eyes was made for the body, the body for the soul, and the soul for God." One may add the passage from (*Rom. 8.*): "Those whom he foreknew, he predestined to be conformed to the image of his Son; those he predestined he also called; those he called he also justified; those he justified he also glorified" — that is, through glory, as Lyran explains in that passage. He who acts out of love for someone acts for the sake of an end, as is clear from the definition of the end; but God does many things out of love for man, and most importantly for the salvation of the human race: "For God so loved the world that he gave his only-begotten Son" (*Ioan. 3.*); and "On account of his exceeding great charity, with which he loved us" (*Eph. 2.*); and the Nicene Creed: "Who for us men and for our salvation descended from the heavens." Furthermore, all things are for the sake of man. Hence (*2. Phys. 24.*), cited by the Doctor (*4. dist. 43. quaest. 2. ante §. Oppositum*): "We are in a certain manner the end of all things." Again, one who wills in an ordered fashion wills the end before the means to attaining the end (*ex 1. dist. 1. quest. un.*); but God is most perfectly ordered in all his works. Finally, the final cause involves no imperfection, as the Doctor proves (*1. dist. 2. quest. 2. art. 1 & 2.*); therefore it is to be attributed to God, and accordingly God acts for the sake of an end, the same Doctor concluding (*ibid. P. Et 3. dist. 32. quaest. vn. §. Tertium patet.*).

Second assertion: the Angel and the human being act for the sake of an end. The Doctor holds this together with Aristotle (*2. Met. T. 9. in com.*): he who possesses intellect acts for the sake of something, that is, for the sake of an end. But the Angel and the human being participate in intellect and reason; therefore they act for the sake of an end. Moreover, both the Angel and the human being are capable of love, on account of which they do many things. Furthermore,

each elects suitable and opportune means for attaining the end; specifically, the physician selects and orders medicine so that the sick person may recover health; therefore he acts for the sake of an end.

Third assertion: brute animals do not properly act for the sake of an end. The Doctor presents this in the passage just cited, saying that only a rational agent acts for the sake of an end; therefore, by the contrapositive, an agent devoid of reason, such as the brute animal, does not act for the sake of an end. The same is indicated in (*1. Met. cap. 1. & ibid. quaest. 3. & 2. d. 42. quest. 1. 4. d. 45. q. 3.*), by Bonaventure (*2. d. 25. quest. 1.*), and by Mayr (*ibid.*). The same is implied by Augustine (*1. Music. cap. 3. Et 1. de lib. arb. c. 7.*). It is proved first: those who do not properly have love do not act for the sake of an end, since to act for the sake of an end means nothing other than to operate out of love of the end; but brute animals do not properly have love, which properly belongs to the will alone, which brutes lack. Second: those who act for the sake of an end know the end itself, apply apt and effective means to obtaining it, compare and discern them from others, and reason about them; but brute animals cannot do these things, since they lack mind and reason; therefore brutes do not properly act for the sake of an end.

You will object first: natural agents devoid of cognition act for the sake of an end (*2. Phys. T. 80.*); therefore this is not to be denied to brutes, which are capable of cognition. The antecedent is confirmed by the right order, beauty, providence, and everlasting conservation of things, which cannot be due to chance and accident, as Aristotle shows against certain ancient Philosophers (*ubi supra.*). I distinguish the antecedent: of themselves, I deny it; by the direction of the first cause, I concede it. For God directs all things toward their ends, by reason of which natural things are said to act for the sake of an end. In this sense the common saying is uttered: the work of nature is the work of intelligence; and: all things that come to be by nature and by art come to be by some reason.

You will object second: the swallow gathers mud, straw, and other materials necessary for building its nest and tending its young. Likewise a dog when shown bread approaches it, and when shown a stick flees. Similarly a sheep flees a wolf, a fly flees a spider, a vine flees laurel; therefore these creatures act for the sake of an end. I respond that these and similar things are done by instinct of nature and a certain shadowy reason, by a resemblance of knowledge and prudence, as Augustine rightly notes (*11. Civit. cap. 7. 11. de genesi ad lit. cap. 2.*), Scotus (*1. Met. quaest. 3.*), and Antonius Andreas (*ibid. quaest. 4.*).

Question IX. On Accidental Causes.

Scotus (*1. d. 2. q. 2. §. Iuxta tres sub N. Et 2. d. 37. §. de modo ponendi.*) teaches that chance and fortune are accidental causes, and Augustine implies it (*2. contra Pelagianos cap. 6. Et 2. ad Bonifacium cap. 7.*). Aristotle treats this at length (*2. Phys.*

c. 4. 5. 6. à T. 39. *usque ad* T. 68.), where the Parisian and other commentators write fully and learnedly about these.

Article I. Whether Chance and Fortune Exist.

Certain Philosophers, whose names Aristotle suppresses (2. *Phys. cap. 4. T. 40.*), and who Fuentes (*ibid. q. 10. dif. 1. art. 1.*) and the Complutenses (*disp. 13. q. 1.*) and formerly Delphinus (1. *de rerum eventu non longè à principio*) testify to be Stoics, eliminate chance and fortune from the world, suspecting that all things come about necessarily and are produced in a determinate manner. The opposite is defended by Aristotle in the passage cited, by Scotus (*Quol. ult.*), and by the other Philosophers and Theologians, with whom we agree.

Assertion: chance and fortune are to be admitted. The Doctor holds this (*ubi supra, & 1. d. 2. quaest. 2. §. ostenso. 11. Met. in com. T. 13. & 5. eiusdem operis, quaest. 1. §. Respondeo.*). This seems to be not so much established by reason by Aristotle as presupposed by common consent, as he likewise presupposes in Logic the tenfold number of the predicaments, as Mayr notes there, and the immobility of place and other things, as Gadius notes (*in expositione Quol. 21. fol. 213. colum. 4.*). But it can be established as follows: cause is rightly divided into essential cause and accidental cause (2. *Phys. T. 50.*); essential causes are those that influx into an effect by their own power and intention, and accidental causes are those that cause an effect beyond their intention, of which kind are fortune and chance. Furthermore, there are fortuitous and casual effects; therefore fortune and chance are to be conceded. The antecedent is evident from experience in many cases — things are sometimes done by us unconsidered and happen by chance, such as the finding of a treasure by those digging a vineyard, or the fall of a stone from a rooftop onto the head of a passerby, and other such things that occur rarely and beyond the intention of the agents.

You will object first: Saint Augustine (1. *Retract. primo*) reproaches himself because he had at some time used the words chance and fortune; therefore in the school of the Christian faithful, chance and fortune are not to be introduced. Scotus responds (*Quol. alleg. §. Quantum ad 1. B.*) that what is rejected is fortune conceived as some divine power, as a Goddess established by the pagans and common people, as Tataret adds (2. *Phys. quaest. ult. scibili primo*), as the artificer of all casual and fortuitous things; but not in the sense in which Catholics teach it, as is evident from the holy Doctor himself (4. *Civit. 18. & 19. & 1. qq. Super Gen. 9. 9.*).

You will object second: all effects have their determined cause, as Plato grants in the *Timaeus*, and Augustine concedes from Cicero (5. *Civit. 9.*); therefore nothing is produced by chance, nothing fortuitously. I distinguish the antecedent: with respect to a remote and universal cause, I concede it; with respect to a proximate and particular cause, I deny it. For many things come

about beyond the intention and awareness of particular agents, as I showed above, and in this sense the authors mentioned are to be understood.

You will object third: nothing in the universe is disordered, unorganized, or out of place, since the Lord has disposed all things in measure, number, and weight (*Sap. 11.*); therefore nothing casual exists, nothing fortuitous. I distinguish the antecedent: with respect to God, I concede it; with respect to us, I deny it. Thus the Doctor (*cit. & 9. Met. q. 9. §. Ad 1. Et infinnuat Aug. 1. 83. qq. q 24. & 27. & 1. 3. de consensu Evangelistarum c. 13.*): to God nothing is fortuitous.

Article II. What Chance and Fortune Are.

Aristotle (*2. Phys. cap. 2.*) and after him Scotus (*Quol. 21.*) and Vives (*5. Civit. cap. 1.*) are extensive and prolific on these topics; but it is difficult and hard to know through investigation what these things are, so much so that the ancient Philosophers depart into various opinions and errors. For some, of whom Democritus is regarded as the chief patron, attribute the making and fashioning of the celestial and elemental spheres to chance and fortune, but exempt from them the sublunar mixed and animate things; many others, to whom the common people of the pagans are favorable, hold fortune to be a Goddess, in accordance with the saying of Juvenal (*Satyr. 10.*): "We make you, Fortune, a Goddess, and place you in the heavens." Aristotle (*l. de bona fortuna*), to whom Bonerus seems to assent (*3. Phys. cap. 1. §. consequens autem*), thinks it is a certain impulse placed in the category of quality. The others, and chiefly Scotus in the places cited, and his disciples, teach that fortune is an accidental cause in those things that proceed from deliberate choice.

Note first, from Scotus (*11. Met. in exp. T. 7.*), that corresponding to a twofold essential agent acting for an end — namely nature and will — there is a twofold accidental cause: chance and fortune. Chance is reduced to the natural cause, and fortune to the free cause. One and the same cause, with respect to different effects, can be called an essential and an accidental cause. It is an essential cause insofar as it produces an intended effect, as a builder constructing a house is called the essential cause of the house he builds. It is an accidental cause insofar as it produces an effect not intended by it, as a builder is the accidental cause of the joy or sadness of those inhabiting the said house. Again, note that an essential cause is said to be one that influxes into an effect by its own power, or one that intends the effect it produces; and likewise an accidental cause is one that does not truly produce the effect but is conjoined to that which gives being to the effect, as a musician builds, where the musician is the accidental cause of the building because he is connected with the one who builds by his own power; or an accidental cause is one that does produce an effect but one not intended by it, and if the cause is natural it is called chance, whereas if it is free it is called fortune.

Note second that chance and fortune are sometimes used interchangeably and confused, in which sense — as Damascus also notes (2. *fidei cap.* 25.) — fortune is predicated of both animate and inanimate things, and of both natural and free things; in this sense stones of a temple and altar are called fortunate and blessed. Nor should one omit that chance has a wider scope than fortune. For what is done by fortune is also said to happen by chance, but not conversely; for what happens fortuitously happens by chance; but properly speaking, fortune applies to a voluntary agent acting by deliberate choice who does not intend the effect, while chance applies to a natural agent not intending the effect, as the Doctor observes above all others (5. *Metaphys. quaest.* 1. §. *Respondeo.*).

Note third, from the Doctor (*Quol. nuper recens. sub D.*) following Aristotle (*lib. de bona fortuna cap.* 1.), that fortune abstracts from good and bad fortune as a genus abstracts from its species, and is used for the cause that produces an unintended effect, and for the unintended effect itself produced by it; if this effect is good, it is called good fortune; if bad, bad fortune. Furthermore, concerning things that are not in our power, such as health, beauty, and the like, we are not properly said to be well-fortuned, since fortune properly concerns those things we do beyond our intention. I add that on account of a single good outcome no one is called well-fortuned, just as one swallow does not make spring, nor does one blessed day make a man blessed (1. *Eth.* 9.); nor even if someone always obtains good things, but only he who rarely beyond his intention receives good and prosperous things, or who avoids evils. But if someone in war, in profit, or in business obtains good and prosperous things for the most part, he is called well-fortuned, and conversely ill-fortuned if in the aforesaid things evils befall him for the most part. Whether these come from an intrinsic or extrinsic source is a difficulty of no small weight to be resolved below.

First assertion: the celestial and elemental spheres were not fashioned by chance and fortune. This is presupposed by the Doctor in the place cited, and is expressly handed down by the same in his commentary (11. *Met. antè T.* 8.) against Aristotle. It is proved first: an essential cause precedes an accidental cause, because the latter is reduced to the former; but nature and intellect are essential causes, while chance and fortune are accidental causes; therefore chance and fortune cannot be the primary causes of things, such as the aforesaid spheres. Second: if inferior things obtain essential causes, as the Philosophers whom Aristotle disputes against (*cit. & 2. Phys.* 44.) acknowledge, then all the more do the heavens, which are superior, well-ordered, and wonderfully disposed, and therefore chance and fortune are not the primary causes of the said spheres.

Second assertion: fortune is not the Goddess of good events devised by the pagans. So Scotus (*Quol. alleg. B.*) after Augustine (4. *Civit. cap.* 18. & 7. *eiusdem, cap.* 3.). It is proved: there would then be two goddesses, one of good events and another of bad, as the Manicheans imagined two primary productive principles

of things, one of good things and another of bad things. Furthermore, we would fall into polytheism, which I shall show to be impossible (*in Met. l. 4. quaest. vn. art. 4.*).

Third assertion: good fortune is an impulse of nature without reason toward the good that someone attains beyond his intention. Scotus rehearses this (*cit. I.*) following Aristotle (*l. de bona fortuna.*). This impulse is called the intrinsic cause of the good outcome, which inheres in the well-fortuned man and inclines him toward good beyond his intention, following upon his individual being; and so one person is well-fortuned and another is not, as is evident from experience. Nor is that impulse sufficient on its own, but extrinsic causes of the good outcome are required to concur and incline toward such good, such as the seven planets in a certain conjunction and aspect both among themselves and with the stars, in a determinate position and house; and when their conjunction is dissolved, the good effects and prosperous outcomes cease. In this way some are fortunate up to their thirtieth or fortieth year and thereafter depart as unhappy and ill-fortuned, as many writers of no little reputation observe. But according to the Theologians, and in particular Scotus (*ad finem loci nominati*), all good outcomes of a human being are to be attributed to the special providence of God, who according to the good pleasure of his will bestows his gifts on one and not on another, nor unjustly, since he is the Lord of all. More on this in Richard (*Quol. 3. quaest. 7.*) and Faber (*de praedest. dist. 57. cap. 5. ad finem.*).

Fourth assertion: fortune is rightly defined as an accidental cause from deliberate choice in those things that happen rarely. So Aristotle (*2. Phys. T. 52.*) and Scotus (*nuper cit. Quol. ult.*). It is called a cause as the genus; accidental, so as to differ from an essential cause; from deliberate choice, because of chance. The remaining particulars are added to distinguish it from nature, whose effects are intended and determinate. Chance, however, is defined as an accidental cause without deliberate choice in those things that happen rarely. The distinction between fortune and chance is clear: the former applies to free agents, the latter to natural agents, as the Doctor correctly sets out (*5. Metaphys. quaest. 1. §. Respondeo.*).

You will object first: Aristotle in some passages, such as (*7. Mor. ad Eudem. c. 18.*), seems to assert that fortune is a Goddess, as the Ancients held, and he does not reject them (*2. Phys. T. 47.*). Hence the Romans worshipped her as a divine power, and Valerius Maximus narrates that her image spoke. I respond that Aristotle there speaks in the opinion of the common people, not in his own opinion; perhaps if he had refuted it they would have inflicted death upon him. His expressed mind is clear from the passages adduced by us in the third and fourth assertions.

You will object second: the same Philosopher (*1. de bona fortuna cap. 2.*) writes that fortune is nature without reason; therefore fortune is not an accidental cause from deliberate choice, which belongs only to free causes. I respond that

the Philosopher in that place indicates that fortuitous effects are produced in us without deliberating reason, as Scotus interprets (*ubi supra*), and because he says it is an impulse and inclination toward the good, toward which the superior natural causes, namely the heavens, concur, he accordingly called it nature without reason. And he adds there: where there is much intellect, there is little fortune, and conversely, where there is much fortune, there is little intellect.

You will object third: many effects, such as eclipses of the sun and moon, occur rarely, and yet they are not attributed to fortune; therefore fortune is not well defined above as applying to those things that as a rule do not come about. I respond by conceding the antecedent and denying the consequence. For such effects are from a determinate cause, which being posited they are posited; whereas fortuitous effects are not of themselves intended or determined by the cause, but arise from other intended and determined effects incidentally, that is, having no necessary connection and bond with them.

Article III. Whether Fate Exists and What it Is.

Gregory (*hom. de Epiph.*), Castrensis (*7. adversus haereses, ver. Fatum*), Suarez (*disp. 19. Met. sect. 11. num. 4.*), and Pontius (*disp. 40.*) warn that fate is to be avoided and indeed denied entirely, as odious and pernicious to the Christian faith. I add Augustine (*Tract. 37. in Ioan.*): "If your heart were not fatuous, you would not believe in fate." For fate is described by the Ancients as a binding of causes drawing its efficacy from the motions and powers of the stars. Hence a certain Poet sings: "Your fates draw you, lest you be able to leave what has been captured," and further: "For he himself, willing and ready, will follow, if the fates call you; the other you will not overcome by any strength, nor will you tear him away with hard iron."

Against these Augustine disputes splendidly (*enarratione in psal. 31.*) in these words: "Many say: fate has made me. What is fate? The stars have made me. What are the stars? Certainly those which we behold in the heaven. And who made them? God. Who ordered them? God. Therefore you see that what you wish to say is: God caused me to sin; thus he is unjust, you are just, because if he had not caused it, you would not have sinned. Remove these excuses from sins, and say with David (*Psal. 140.*): 'Let not my heart incline to evil words, to make excuses in sins with men who work iniquity.'"

Fate is defined otherwise by Seneca (*1. 2. qq. naturalium cap. 36.*) as the inevitable order of things and the inescapable chain of events, which no force can break, because it depends upon the disposition of Jove and the settled counsel of the Gods. Toward this Virgil looks (*4. Aeneid.*): "If the fates were to permit me to lead my life under my own auspices, and to compose my cares by my own free will." Such fate is condemned in the Council of Braga I, c. 9, and refuted by Augustine (*1. haeresium cap. 35. Et 5. Civit. c. 1. & inde*), where Vives and Alfonso (*7. adversus haer. ver. Fat.*), and is refuted by reason. For in this way human freedom would

be injured; commerce and deliberation admitted in (*1. perih. cap. ult.*) would be abolished; nor would any man be worthy of praise or blame, nor worthy of reward or punishment, as Alfonso shows fully and learnedly (*ubi supra.*). For if all things happen necessarily and inevitably, there would be no contingency of things, no indifference and indetermination to opposites, and similar things; all of which are false, absurd, and heretical, and therefore fate in this acceptation, which is the customary one according to Bonaventure (*2. d. 14. quest. 3. num. 79.*), is to be detested and execrated.

Fate is described a third way by Bonaventure (*3. Phys. cap. 2.*), Auriol (*1. d. 40. art. 3.*), Gadius (*quol. 21.*), and Molina (*1. p. quest. 14. art. 13. disp. 1.*) as the order and connection of secondary causes foreseen by God, according to which God permits things to act and come about. This description is derived from the notion of the name. For fate is derived from the verb to speak, as Augustine notes (*tract. 37. in Ioan. Et 4. contra Iulianum cap. 8. Et quest. 115. novi & veteris testamenti*). Hence things are thought to come about by fate which have been foretold by someone beforehand, according to the same Augustine (*5. Civit. cap. 2. Ocontrà Faustum 2. cap. 5.*). Since, therefore, to happen by fate is equivalent to being foretold, foreseen, and predicted, according to the etymological meaning of the word, plainly the certain and determinate order of all concurring causes toward the production of effects, and their arrangement foreknown and foreseen by God, is called fate. In this way fate, taken broadly and generically, abstracting from good and bad, Boethius (*4. de cons. prof. 6.*) restricts to the good alone and specifies it for those effects that are subject to divine providence, so that fate, according to this author, is the order of secondary causes executing divine providence. To this sense a certain interpreter of Pliny (*1. 20. cap. 1.*) refers the opinion of the Ancients, saying: "Homer's chain and Plato's rings are nothing other than the series of things and the order of divine providence serving as its instrument." For the series and order of divine providence is infallible, not impairing created freedom nor destroying the contingency of things. Hence Manilius rightly sings: "Nor in so great a mass is anything more wonderful than reason, because all things obey certain laws."

You will say: what has been foreknown, foreseen, and ordained by God is firm, stable, and infallible; therefore if fate is conceded as a certain and determinate series of causes foreseen and provided for by God, plainly the effects of those causes will come about necessarily, because they will come about as God foresaw them to be future, and so fate is admitted in the same sense as the Ancients concede it. I concede the antecedent and deny the consequence. The reason is that the foreknowledge of God does not remove contingency or freedom, since it is extrinsic to things. Hence it is only inferred that things will infallibly come about, but not that they will come about inevitably and necessarily — with the necessity of the consequence, not of the consequent — as I showed (*in Log. l. 4. art. ult.*).

Article IV. On Monsters.

A monster, which derives from showing (*monstrando*), as Augustine notes (21. *Civit. cap. 8.*) — either because it shows and predicts some future event, as Cicero says (2. *de natura Deorum*), or because it points out with fingers, as it were, something wonderful and unusual that all are to behold, as others prefer — is called by Aristotle a sin of nature (2. *Phys. 82.*), a defect and deformity of the same (7. *Met. c. 9. T. 31.*), and also an evil of nature itself by Scotus (1. *Rep. d. 2. q. 3. §. Ad 1. principale.*). Most importantly it is defined as a natural effect degenerating from the right and usual disposition according to its species, gathered from (2. *Phys. cit. 4. de gener. animalium cap. 4.*) and expressed with respect to all its particulars. It is called an effect, as the genus. It is called natural, because in artificial products, if some defect occurs, it is called not a monster but an error. The remaining particulars are added in place of the differentia. For since each species has its individuals that are constituted and integrated in the customary manner from certain parts and determinate members, if any individual of a species is generated having all its members, or some more notable and remarkable ones, deviating from the right and customary mode in which the others exist, it is called a monster. This occurred in the ninety-first year of Christ, when a certain monster was found with a canine head and the other members human, which presaged that century would be exhausted of men of talent and learning, as Genebrard notes (4. *Chronol. p. 317. decimo saeculo.*). Although the Parisians (2. *Phys. q. 2. fol. 45.*) write that monsters occur in nearly all created things, I think that they properly come about in animate things, such as plants and trees — so Pliny reports (1. 7. c. 2.) that under the shade of a single fig tree an entire army lay encamped — and most of all in human beings and brute animals, as occurred in the year of Christ 1105, when a sow gave birth to offspring with a human face, a cock was found with four feet, and a two-headed child of double sex was born, as Genebrard attests (*cit. pag. 356. saeculo duodecimo.*). The principal causes of monsters can be assigned as fourfold: abundance of matter, deficiency of matter, intemperate condition of matter, defect in what contains the fetus, and mixture of animals of different species, of which Pliny makes mention (*lib. 6. hist. cap. 30.*).

First, then, a monster can be born from excess of matter, and this in two ways. Either the excess of matter occurs in all the parts and members of the animal — thus Augustine narrates (16. *Civit. cap. 23.*) that certain persons at Rome had bodies of gigantic size; and in the year 1649 in the month of July a tortoise was found at Aquae of such great size that it struck those who beheld it with amazement — or an excess of matter is found only in some member or members. Thus Genebrard writes (2. *Chronol. ad annum urbis Romae conditae 512.*) that at Rome a boy was born of a maidservant walking on all fours, also having four eyes and ears and a double masculine sex. Likewise hermaphrodites, or androgynes, are sometimes seen having both masculine and feminine sex, of

which Augustine (12. *Trin. ante cap. 7.*), Aristotle (4. *de gener. animalium, cap. 2.*), and Angelus (*verbo Hermaphroditus*) make mention.

Second, a monster arises from deficiency and smallness of matter, and this in two ways. Either matter is deficient proportionally in all the parts and members of the animal, and in this way a dwarf is born; hence Nicephorus (12. *hist. capit. 37.*) reports that in Egypt there existed a man of such tiny stature that he reached only the size of a partridge. Or it is deficient in some part and member, in which way monoculi, monopeds, and umbripeds are born, of whom Pliny speaks (7. *Hist. cap. 2.*). Hence the Parisians in the passage just cited say that in their own time a girl was born deprived of eyes and nose, having in place of nostrils only two openings.

Third, from intemperate condition of matter. For if matter is excessively hot and burning, children are sometimes born with teeth — such was Marcus Curius, according to Pliny cited above — and with beards. Thus Albert, cited by the Parisians (*ubi supra*), attests to having seen a girl born with pendulous breasts and hairy under the arms, on the head, and in the groin. But if matter is excessively cold, there are generated those who are cold and bewitched, unfit for intercourse and generation, of whom Angelus (*verbo Matrimonium impedimento 16.*) and Lyran (*ad finem, c. 1. Geneseos*) speak.

Fourth, from a defect in what contains the fetus in the womb of the mother, monsters are seen. For if the containing structure — a certain thin membrane called the afterbirth — is violently compressed or broken, then one fetus is joined to another and they emerge together from the mother's womb. Thus in the year 1623 two infants appeared joined together in the womb, of whom one bore the other, one ate and drank and spoke, while the other did not, but only emitted foam from his mouth. Scotus rehearses something similar (4. *distinct. 6. quest. 2. §. De quarto I.*).

Fifth, from the mixture of animals of different species, as occurs in Africa, where on account of the scarcity of springs animals of different species come together to drink and there mingle and mate, producing various monsters, as Aristotle affirms (8. *de generatione animalium, cap. 28.*). In this way sometimes semi-men, semi-beasts are born. Likewise a woman gave birth to a serpent, according to Lucian; and an ox to a lamb, according to Josephus (7. *de bello Iudaico, cap. 12.*).

You will ask first: whether a monster having doubled members, namely two heads, four hands, and feet, is one animal or many? I respond with Aristotle (4. *de generatione animalium*): if the heart is one, it is one animal; but if the heart is double, the animal is likewise doubled. The reason is that the heart is the origin and seat of life, and therefore from its unity or duality one or more animals are established. And this is discerned from the pulse, as Scotus adds (4. *distinct. 6. quæst. 2. §. De quarto. I.*). And in adults, from the intellect and will. For since a

human being is one animal by reason of the unity of the rational soul, which possesses one intellect and will, from these it is consequently easy to know whether the animal is one or many.

You will ask second: whether nature intends a monster? I respond that it does not intend a monster essentially but accidentally. The reason is that a monster, as has been said, is an evil, which nature does not intend essentially but accidentally on account of the impediments enumerated above. So the Seraphic Doctor seems to hand down (*2. distinct. 7. quaestio. 3.*), and in a similar case Scotus writes (*1. distinct. 41. quaest. un. §. Contra istam positionem.*). I add that nature intends what is right and perfect, in accordance with the saying: nature does what is best. But if it is impeded through the causes enumerated above, it tends toward the oblique and imperfect, of which kind is a monster.

Book V. On Quantity.

What I disputed about quantity, its essence, species, affections, and series in Logic (*lib. 3. quaest. 4.*) is to be presupposed. With these things presupposed and laid as a foundation, we take care to add here the remaining things that are desired there, especially because quantity is a property of natural body, pertaining to this branch of doctrine.

Question I. On Quantity in Common.

Article I. Whether Quantity Can Exist without External Extension to Place.

No one doubts that by the power of nature internal extension cannot exist without external extension or local commensuration, because the latter presupposes the former as an effect presupposes its cause, just as light presupposes a luminous body. Whether this can be brought about by God's supernatural power, however, is a controversy among Catholics and heretics. For Luther and Calvin (*4. instit. cap. 17.*), to whom Durant (*4. dist. 10. quaest. 2.*) seems to lend support, think it repugnant for the external extension of quantity to place to be separated from the internal extension of parts in a whole. Scotus (*4. distinct. 10. quaest. 1. art. 2. §. Dico ergo aliter M.*), Ballius (*ibid.*), Mayr (*quaest. 2.*), and the other Orthodox Doctors teach that it can be brought about divinely that the internal extension of the quantity of a quantified body should exist without external extension to place.

Note that extension, which by the force of the name is equivalent to a stretching outward, as Mayr notes (*ubi supra, quaest. 3.*), is a position of parts, and is twofold: one is internal, which is the position of parts in a whole; the other is external, which is the position of parts in a place. The former belongs to the genus of

quantity, the latter to the genus of situation (*situs*); and the former can exist without the latter. For God can bring it about that a quantified body is not measured and inscribed by place, as if it were placed outside the heavens; and if it exists within the heavens, it enjoys the former position but not the latter.

Assertion: by divine power the internal extension of quantity can exist without external extension to place. The Doctor holds this (*cit. & in Report. eadem dist.*). It is proved first from Sacred Scripture: "But he, passing through the midst of them, went his way" (*Luc. 4.*); and "But Jesus hid himself and went out of the temple" (*Ioan. 8.*), where Lyran adds: Christ by the power of his divinity renders himself invisible to them; but he could not have done this except by the separation of external extension from the internal extension of quantity, as occurs daily in the Eucharist, in which the body of Christ has no actual external extension to place but only aptitudinal extension, as Suarez also maintains (*disp. 40. Met. sect. 4. num. 14.*). Second: in essentially subordinated things the prior can exist without the posterior, as is clear from God, the sun, and man, as well as from a cause and its effect; but the internal extension of the quantity of parts in a whole and the external local and commensuratory extension of the parts of the whole in a place are subordinated to each other, with the internal extension established as prior — which is the essential reason of quantity, as I proved (*in Log. pract. art. 2.*) — and as the cause of external local and circumscriptive extension. But a cause can exist without its effect, as the Doctor writes (*4. distinct. 49. quaest. 13. & 16. §. Dicunt quidam.*). This was demonstrated in the Babylonian furnace, in which the three Hebrew children who were placed there were not burned. Third: the predicaments are unmixed, and nearly all are really distinct from one another; but the aforesaid extensions belong to different predicaments. For internal extension pertains to the predicament of quantity and external extension to the predicament of situation, as I noted above. Therefore they can be separated from each other, and accordingly the former extension of quantity can exist without the latter.

You will object first: Saint Augustine (*epist. 49. ad Dardanum*) commits these words to writing: "Take away spaces of places from bodies, and they will be nowhere; and if they are nowhere, they will not be." From these words the holy Doctor clearly implies that bodies cannot exist without local extension, which is external extension. I respond that Augustine there speaks of natural power, not of divine power, which extends to everything that does not involve a contradiction.

You will object second: a continuum is that which has extended parts, with one part outside another, and which can be divided into them (*5. Met. cap. 13. T. 18.*); but this extension of parts respects place, because it does not seem possible how the whole body and its parts can be extended except in relation to place; therefore the internal extension of quantity cannot be separated from external extension, which is local and commensuratory. I concede the major and deny

the minor. For "with God no word is impossible" (*Luc. 1.*). Hence, although this cannot be brought about naturally, it is shown to be possible supernaturally through the reasons given above in support of the preceding assertion.

You will object third: a continuous quantum cannot exist without figure; but figure by its very nature requires local extension; therefore a quantum cannot exist without local extension. I respond first that a quantum can exist without figure, which is in the fourth species of the genus of quality. Furthermore, a quantum can exist without external and situational figure, but not without internal figure, which is its intrinsic terminus, residing in the category of quantity.

You will object fourth: nothing is found without its property or passion, as a man is not found without risibility; but external extension is the passion of quantity; therefore quantity cannot exist without it, and conversely. I concede the major and deny the minor: for external extension is the effect of internal extension, and that a cause can be found without its effect was shown above. Or you may say that internal extension can exist without actual external extension, just as a man can exist without actual risibility, but not without aptitudinal external extension to place; just as a man cannot exist without the power and aptitude for laughing.

Article II. Whether Quantity Is Really Distinct from Substance.

Scotus (*4. distinct. 1. §. Ad quaest. ergo sub I.*) rehearses two opinions. One is followed by the Nominalists — Ockham (*4. dist. 4. & Quol. 4. quaest. 29.*), Gabriel (*in can. lect. 43.*), and the others of the same school — who assert that quantity coincides and is identified with corporeal substance and material accidents, so that there are as many quantities in a composite as there are substances and material accidents in it. According to these authors, therefore, material substance is of itself quantified insofar as it has parts outside of parts, and color is likewise of itself quantified insofar as it has its own parts extended per se. The other is the common opinion embraced by the Doctor in the passage cited, by Mayr, Basson, and others there, to whom the Thomists assent following Thomas, cited by the Complutenses (*disp. 13. Phys. quest. 1.*), and Suarez (*disp. 40. Sect. 2. num. 7.*), who teach that quantity is really distinct from substance and from every material accident. The same is handed down by Bonaventure (*4. distinct. 12. art. 1. quaest. 3. prope finem.*); nor does Durant dissent (*ibid. quaest. 1. ad 2.*).

Presupposed is the division of being into substance, which is being subsisting per se, and accident, which is being inhering in another. This is subdivided into absolute and relative; the former can exist without a subject, the latter in no way can, since it depends upon it both in its becoming and in its being, as I showed at length (*in Log. lib. 3. quaest. 6. art. 5.*).

Assertion: quantity really differs from corporeal substance. So Scotus (*passim alleg. Et 2. distinct. 2. quaest. 9. Et distinct. 12. quaest. 1.*) and also (*5. Met. quaest. 9.*), following Augustine (*5. Trin. cap. 10. & 8. eiusdem operis, cap. 2.*). It is established first from Aristotle, both in Logic in the chapter on quantity, and in the Metaphysics (*lib. 5. cap. de quanto*), where the Philosopher distinguishes quantity from substance. Likewise (*1. Phys. T. 15.*), disputing against Parmenides and Melissus, he writes that what are other than substance are predicated of substance, but quantity is predicated of substance; for one can say "substance is quantified," therefore quantity is separated from substance. The same in (*7. Met. T. 3. ibid. sum. 2. cap. 1. 7. 8.*), where in explicit words he adds: "Length and width and depth are certain quantities, but they are not substance. For quantity is not substance." Furthermore, the Stagirite himself not infrequently, as in the 3rd and 7th books of the Metaphysics and other places, refutes the Pythagoreans and Platonists who make numbers and quantities the substances of things. And unless he distinguished quantity from substance, just as there is per se motion for quantity, there would likewise be per se motion for substance, which he expressly denies (*5. Phys. T. 18.*). Second: things that are really different are such that when one persists the other perishes, as the Doctor acutely argues (*2. distinct. 1. quaest. 4. §. Contra istam*). But in the Eucharist the substance of bread does not remain, as faith teaches and the Council of Trent declares (*Ses. 13. can. 2.*). Yet its quantity persists, as the senses perceive and reason establishes. For one quantity of this host is discerned, in which color, taste, smell, and the other qualities reside as in a common subject.

You will say there are as many quantities as there are qualities, identified with them in reality. On the contrary: those qualities are not disjunct and dispersed but are united and ordered to one another; therefore they are united and ordered in a common subject, which is quantity really distinct from them. And this is evident in a bench and other artificial products, which are common subjects for the things placed in them. Third: no accident is identified with substance, since being is openly distributed into substance and accident as into opposed members; but quantity is an accident and is established as one of the nine predicaments of accident; therefore quantity is really separated from substance. Ockham answers (*Quol. citat.*) by conceding the major and distinguishing the minor: if quantity is taken personally, as it supposits for an individual such as Peter, he denies it — for in this case it coincides with his substance; but if it supposits simply, he concedes it — for in this case it is taken for the word or concept, which is an accident. On the contrary: if quantity supposits personally, it is taken for this or that singular quantity; but if it supposits simply, it is taken for generic or specific common quantity signified by the name, as I explained (*in Epitome lib. 1. quaest. 2. art. 3.*). In whatever way quantity is taken, therefore, it is an accident. Furthermore, however quantity is taken, it is a being in another, namely in a subject which is substance; therefore it is an accident in such a way that it can in no manner be substance. Fourth:

things that are of different genus and species differ from each other, in accordance with the rule before the predicaments: of different genera there are different differentiae, species, and individuals; but substance and quantity are of different genera, being of different predicaments — as fire is in the genus of substance, while its length and breadth are in the genus of quantity — therefore quantity is distinguished from substance. The aforesaid Ockham answers, from Damascus as cited by him, by conceding the major and distinguishing the minor: with respect to the same intention, he denies it; with respect to different intention, he concedes it; for fire insofar as it is a substance is placed in the predicament of substance, but insofar as it is quantified, it is in the category of quantity. On the contrary: either the same or different intention or consideration does not identify or differentiate things, but is borne toward them as they are from the side of things. Hence it is called the same intention because it tends toward the same object, and different because it reaches a different object; but substance and quantity are distinct things, as is clear from their definitions; therefore they really differ from each other. Damascus, however, speaks of things that differ by reason alone, as he signifies (*lib. 1. fidei, cap. 11.*), not of things that are separated from the side of things, since the thing is prior to its signification and distinction, as Augustine implies (*quaest. 2. veteris testamenti.*).

You will object first, from (*1. Phys. T. 52.*): beings are not to be multiplied without necessity; but if quantity is posited as something distinct from material substance, beings would be multiplied without necessity, since substance of itself is extended and divisible into parts without anything added to it; therefore quantity does not really differ from it. I concede the major and deny the minor and its proof. For corporeal substance is extended and divisible into quantitative parts through quantity, just as it is white through whiteness and morally formed through a habit.

You will object second: things that possess the same properties do not differ from each other, for the same property argues the same essence; but substance and quantity share the same property, for each admits of contraries, such as whiteness and blackness and others of this kind; therefore there is no distinction between them. I concede the major and deny the minor; to its proof I say that substance and quantity admit contraries in different ways. For quantity is their proximate and immediate subject in the sense of *quo*, while substance is the remote, mediate, and ultimate subject in the sense of *quod*. Or you may say that the argument is valid of a property in the fourth mode, but not of those in the other modes. For receiving contraries of this kind is a property that belongs to substance and quantity in a certain sense. But the property of substance in the fourth mode is not to be in another, and the property of quantity in the fourth mode is to be equal or unequal, as I said (*in Epitome lib. 1. quaest. 4.*).

You will object third: if quantity were really distinct from substance, in rarefaction a new quantity would be acquired, since new extension of parts occurs through it; and in condensation quantity would be lost, because through condensation parts are contracted and occupy a smaller place. But this seems inconvenient; therefore, etc. The consequence of the major can be conceded, as will be evident (*lib. 2. de intensione & remissione, quest. 2. artic. 1. affert. 3.*) And the minor is to be denied from what will be said there.

Article III. Whether Quantity Divides Material Substance into Its Parts.

Albertus (*lib. Tract. 2. cap. 4.*), Durant (*1. distinct. 34. in calce, quaest. 1.*), and others whom the Complutenses cite and follow (*disp. 13. Log. quest. 3.*) deny that corporeal substance is divisible into any parts prior to quantity. Scotus (*2. distinct. 12. quest. 2. §. Respondeo D.*), Ockham (*Quol. 4. quaest. 14.*), and the adherents of both assert that material substance is first constituted with substantial and entitative parts before it is divided into quantitative parts.

Note first, from (*Epitome lib. 2. quaest. 7. art. 1.*), that a whole is principally of two kinds, essential and integral: the former is subdivided into physical, which consists of matter and form, and metaphysical, which is constituted from genus and differentia. The latter is subdivided into homogeneous, which has similar parts of the same nature — as water divided into parts yields parts of which each is both in reality and in name water — and heterogeneous, which has dissimilar parts diverse both in reality and in name, as a body is divided into head, neck, arms, hands, and other organic parts of this kind. In the present question the controversy is only about the physical whole, both homogeneous and heterogeneous, as to whether it borrows the aforesaid parts from quantity.

Note second that extensibility belongs to material substance as its property prior to the advent of quantity. For to be extensible is one thing and to be extended is another: the first material substance has from itself, since it flows from its essential principles; the second it receives from quantity. Hence the Complutenses mentioned above are not right in thinking that our authors err in attributing to the said substance divisibility into entitative parts. For we admit in that substance the capacity for receiving quantity, and in the same substance, prior to the reception of quantity, the privation of it; but beyond quantity, we assert that material substance is divisible into entitative parts just as into essential parts, such as genus and differentia; and with the advent of quantity, into quantitative and local commensuratory and circumscriptive parts.

Assertion: material substance is prior of itself divisible into entitative parts than into quantitative parts through the benefit of quantity. The Doctor holds this (*ubi supra*), to whom Auriol, Mayr, Suarez (*disp. 40. Met. Sect. 4.*), and Fonseca (*5. Met. cap. 13. quaest. 2. sect. 3.*) adhere. It is proved first: a substantial whole is first constituted and composed from intrinsic and substantial parts before extrinsic

and accidental ones. For a thing is first constituted in itself and in its own being before it respects another, as is evident from a subject, which precedes the accidents that are based in it, and from a cause, which precedes the effect that proceeds from it; but material substance is an integral whole consisting of entitative and substantial parts intrinsic to it, as is evident from the first note. And this can be further clarified and corroborated by an analogy with quality, which possesses intrinsic degrees before it is affected by quantity; therefore material substance is first divisible into substantial parts than into quantitative ones.

The Complutenses named above respond by denying that material substance has any parts in act prior to quantity, but that parts arise from quantity, through which it is extended and divided into parts; and that substance possesses only the capacity for receiving this kind of extension of parts. Thus the substance itself prior to quantity is neither an integral whole nor does it have any actual parts. On the contrary: material substance is truly a substance, since it is a being subsisting per se residing in the category of substance, and its parts are likewise substances pertaining to the same predicament — as a part of water is water and differs substantially from another part of water — therefore either such substance receives substantial being from quantity or it does not. Not the first, because it is presupposed to already be a substance before quantity comes to it. If the second: therefore, apart from quantity, the aforesaid substantial entities preexist in that substance, for by the adversaries quantity merely confers extension upon them; but so that something may be extended, it must be presupposed and prerequired to have something that may be diffused. Since, therefore, quantity extends the said parts, it is plainly deduced that these parts precede quantity. All the more: if from some whole, say a piece of wood, God were to remove its quantity — which the adversaries cannot deny to be possible, since quantity really differs from substance, and as a matter of fact in the Eucharist the quantity of bread exists without its substance — its substantial and entitative parts would remain. This argument is confirmed with such weight of truth that it has persuaded even certain Thomists, notably John of Saint Thomas, to admit the aforesaid entitative parts, though disordered and confused. But this helps them not at all, since if God were to allow them to exist as they were previously when they were affected by quantity, they would be disposed and ordered among themselves, albeit not extended and not quantified. Nor does it help to say that they cease to be parts, for although they cease to be quantified and extended, they do not cease to be substances, since their substantial being is preserved by God while only their being as extended departs. This the Complutenses seem to scent (*passim alleg. num. 43.*) when they define quantity as an extension-conferring accident of substance. Second: a divisible accident presupposes and requires a divisible subject, as Averroes hands down (*3. coli.*), and the reason is that between what receives and what is received there is a proportion, which would not obtain unless both were

divisible; but quantity is a divisible accident whose subject is material substance; therefore material substance of itself is divisible into substantial parts. The Complutenses respond (*citat. num. 39.*) by distinguishing: in potency and privatively, they concede; in act and positively, they deny. On the contrary: material substance differs from spiritual substance in this, that the latter is indivisible — as the rational soul is whole in the whole body and whole in any part of the body — while the former is divisible: for the sentient soul is whole in the whole body and a part in a part of the body. For if it were whole in any part of the body, when that part were severed the whole soul would perish, which is false and contrary to experience; therefore material substance is actually and positively divisible into substantial parts. Furthermore, through nutrition, a new part of substance is generated that, at least by nature, precedes its quantity, and is added to the previously existing animate whole. Moreover, from (*2. de generatione T. 37.*): from a fistful of air ten fistfuls of fire are made; but this plurality is not derived from quantity, because in terms of quantity two fistfuls are equal; therefore it is derived in terms of substance, and accordingly material substance is divisible into its entities. I add: if a priest were to consecrate the half of a host and were not to consecrate the other half, the substance of the bread in the middle would cease to be in the consecrated part and would be separated from the substance of the bread remaining in the other unconsecrated half, and yet the quantity of the whole host would remain integral and undivided; therefore, given this hypothesis, there would be a division of substance into entitative parts. Nor is it satisfactory to say that it is the same quantity not according to reality but according to appearance — for that is ridiculous, absurd, and contrary to sense and experience. Nor similarly is it satisfactory to respond that there is not properly speaking a separation of one part from the other but a cessation. For if God were to preserve that part of the substance of the bread outside the host without quantity, just as he preserves the quantity without its subject and substance, without doubt there would be a true and real separation of substance into its entities, with the quantity remaining intact.

You will object first: the essence of quantity is extension of parts, and its property is divisibility, according to the common position of Philosophers; but substance is really separated from quantity, as has been asserted in the preceding article; therefore substance is not divisible into parts except through the benefit of quantity, as Aristotle implies (*1. Phys. T. 15.*). Confirmed: no indistinct principle is divisible, because every divisible is distinguishable into many; but substance, and especially matter, is an indistinct principle, since it is potency and act distinguishes and separates (*7. Met. 49.*); therefore substance is not divisible into many entities. I distinguish the major: into entitative parts, I deny it; into quantitative parts, I concede it, as I made clear abundantly above. Through the same distinction the instantiation of the confirmation is resolved.

You will object second: prior to quantity, no composition of entitative parts can exist in substance; therefore substance of itself is not divisible but only through

quantity. The antecedent is proved: the composition of substantial parts is accidental, because it does not consist of act and potency simply speaking, since one part does not provide being to the other nor constitute it. I distinguish the antecedent: of composition taken strictly, which is called essential, I concede it; of composition taken broadly, I deny it. To the proof I deny the antecedent, the reason being that material substance has substantial parts that integrate the whole substance; hence it is called not accidental but substantial, although their union is a relative accident, just as in essential composition from matter and form as well.

You will object third: matter is either simple or composite; not simple, for then it would be indivisible; nor composite, for it is not constituted from act and potency, since it is itself potency, nor from subject and accident, since it is a being per se; therefore it is in no way divisible. I respond that matter consists of entitative parts which, since they are of the same nature, do not denote a true composition such as is had from matter and form, as the argument proves; just as quality is said to be simple, even though it coalesces from many grades of the same nature.

Article IV. What Is the Subject of Quantity.

Since from what has been said quantity is an accident, and every accident requires a subject in which it inheres, it is rightly investigated in the present what is to be established as the subject of quantity. The dispute between Philosophers is about two candidates, namely matter and the composite. The Averroists and Nominalists, whom Achillinus (*lib. de elementis. cap. 17.*), Zabarella (*2. de materia, cap. 8.*), Suarez (*disp. 14. Met. sect. 3.*), and others hold, judge that quantity is proximately and immediately based in matter. The Scotists with their Doctor (*2. dist. 3. quaest. 4. §. Ad 1. rationem ante M. Et dist. 15. quest. vn. §. Dico ad quaest. A. Et 4. distinct. 12. quaest. 4. §. Ad quaest. ergo G.*) and the Thomists with their leader (*1. p. quest. 76. art. 6.*) and other places subscribe to Durant (*1. dist. 5. quest. 4. parte secunda. Et 2. distinct. 12. quaest. 2. Et 4. dist. 12. quest. 1.*), Richard (*4. d. eadem, quaest. 1.*), Bonaventure (*ibidem, art. 1. quest. 1.*), and Rivius (*de gener. cap. 4. Tract. 3. quaest. 8.*), teaching that the subject of quantity is the composite.

Note first, from Scotus (*4. distinct. 12. quaest. 2. §. Ad quaest. ergo 1.*), that accidents are of two kinds: some are relative, having their being toward another without which they can neither exist nor be mutually separated, and these are called imperfect and of minimal entity; some, however, are absolute, really distinct from the subjects in which they exist, and these are called perfect accidents, of which kind are quantity and quality, which can be separated from one another and from the subjects in which they inhere by divine power.

Note second that there is one subject of inherence and another of denomination. The former is that in which accidents are based — as the soul is the subject of inherence of intellectual cognition, because cognition inheres in

it. The latter is the subject of denomination, that which is denominated by such an accident, even if that accident does not wholly inhere in it but in a part of it — as a man is called intelligent even though intellectual cognition inheres only in his soul, or is terminated in it; likewise a bench is called a human work, because the action of the man producing it is terminated at it. Furthermore, the subject is divided into adequate or total and inadequate or partial, the explanation of which is found (*in Log. lib. 1. quaest. 3. art. 1.*). And likewise into immediate or proximate and mediate or remote, of which in the same place.

Assertion: not matter but the composite is the immediate and proximate subject of quantity and of the other accidents. The Doctor holds this (*ubi supra. Et in Report. ibid. Et Theor. 22.*). It is proved first by various testimonies from Aristotle, from which I select three that are more weighty and effective. The first is derived from Logic, chapter on substance: "When first substances are destroyed, it is impossible for anything to remain." The Philosopher speaks there of perfect and complete substances, which are the singular and individual members of the predicament of substance, and which are said to be substance in the highest degree because they underlie or are subjected to all essential and accidental predicates. For of Peter, for instance, it is predicated that he is a living substance, a rational animal, great, white, and similar things, which are truly in him and in other individuals of the same genus. And lest anyone say that these belong to the said substances by reason of the part or matter they contain, he adds in that place, closing off the way to dissolving the force of this instance: although parts are substances, they are nevertheless incomplete and are referred to the whole substance, which is individual and substance in the highest degree, because it underlies all the said predicates, all things are predicated of it, while it is predicated of nothing. If that same substance is destroyed, surely all things that are in it are destroyed, among which are the accidents and especially quantity. But matter, which is a part of it, is not destroyed, since it is incorruptible (*1. Phys. 7. 82.*); therefore quantity does not inhere immediately in matter but in the composite, according to Aristotle. The second is from (*5. Phys. cap. 1. T. 3.*): the subject of motion is the composite, for example wood or man. And (*1. de gen. cap. 4. T. 23.*), establishing the difference between generation and alteration, he says that the subject of generation is matter, of alteration the composite; for a man is altered when from sick he becomes healthy, from hot cold, and from bad good. Nor does it help to say that the whole is the subject of denomination while matter is the subject of inherence; for it is manifestly evident in the text that the Stagirite is speaking of the subject of inherence, since alteration inheres in the whole, namely motion, health, and similar things in man or another animal. The third is from (*Met. lib. 7. T. 4. & lib. 12. T. 43.*): substance precedes accident in nature, cognition, and time. He treats there principally of composite substance, for he brings examples from elements and mixed things, and most of all from plants and animals, which are composite and complete substances. And at (*T. 9.*) he promises to pass over the discourse about the third substance, which is the

composite. Nor does it help to respond with Suarez (*citat. num. 55.*) and Arriaga (*disp. 5. Phys. sect. 2. subsect. 1.*) that the argument concludes with respect to the order of intention but not of execution. For things that are prior in intention are posterior in execution, from Scotus (*1. Reportat. distinct. 41. quest. vn. §. Dices post Aristot. 7. Met. T. 7.*). And nature in its works proceeds in such a way as to begin from the more imperfect and advance to the more perfect. Hence if fire is generated in wood, the wood is first disposed by heat and dryness, which are prior dispositions for its generation, and these are followed by the generated fire, which is the substance; while those precede, being accidents. On the contrary: substance, not only partial but also total, precedes quantity and the other accidents in the order of execution; for the subject is prior in the order of execution to those things that are based in it and depend upon it for existence and conservation; but total substance is said to be the subject of quantity in this order, because it is a being simply speaking and independent of it, and its cause; especially because a thing is first completed and perfected in its own genus before it respects other things of a different genus in the order of execution; but form, by which matter is specified and perfected, is of the same genus as matter, since each is a substance; therefore matter is presupposed informed by its substantial form, and accordingly is a total substance, before it receives quantity. Hence that saying: "what are prior in intention are posterior in execution, and what are prior in generation are posterior in perfection," does not apply in the same genus but in different genera. For an accident is posterior to substance both in generation and in perfection and in execution. The prior dispositive qualities, however, are not based in the whole being generated, since it does not yet exist, but in the whole being corrupted, which truly exists. Therefore the instance of the prior dispositions has no weight for enervating the foregoing argument. Third, from (*1. anima T. 66. & lib. de sensu & sensato, cap. 1.*): sensitive operations belong to the whole composite — as weaving, building, and the like belong to man — and vision, hearing, and similar things reside in organs, such as vision in the eye and hearing in the ear; but the organs are composites of both body and soul in part. Therefore these and other accidents are based in the whole. The adversaries respond that the aforesaid accidents are in the whole as in a subject of denomination, but in a part of matter as in a subject of inherence. On the contrary: the organ of vision, which is composed of matter and form, is not only denominated seeing through the vision by which the eye sees, but also through the same vision received in it; for to sense is to be acted upon, just as to understand is (*3. anima T. 12.*). All the more: vision comes about from the visible species received in the eye and from the visual power as two partial causes integrating one total cause; but the visible species inheres immediately not in matter but in the eye, which is an organ of the whole composite. Furthermore, immanent operations, among which is vision, are the ends and perfective termini of powers (*9. Met. T. 16.*); but perfection immediately and proximately inheres in the perfectible; therefore the aforesaid operations, as well as the other accidents, are based in the whole. Fourth: quantity exists proximately in that in

which motion toward its acquisition immediately exists, as is evident (*5. Phys. 3. & 8.*); but the proximate and immediate subject of motion is the composite, as the Stagirite there clearly expresses concerning wood receiving the motion of heat and cold. Furthermore, if motion were received immediately in matter, no motion would be violent but all would be natural or neutral, as the Doctor deduces (*2. dist. 18. quest. vn. §. contrà primum. D.*). Again, according to the Averroists there is no matter in the heavens, yet there is motion and quantity in them. Moreover, if matter stripped of all form were to exist — which is divinely possible — it would be circumscribed by place on account of the quantity existing in it, which is the reason for local circumscription. And if quantity were admitted as a property of matter, it could not be separated from it, since a property formally differs only from the thing of which it is a property; and therefore in the Eucharist the quantity of bread would not be separated from its matter, which contradicts the common position of the scholastics, as is evident from the Doctor (*4. dist. 12. quest. 2.*). These and other things that can be brought forward to confirm and corroborate the foregoing assertion render it not only more probable but also more true, especially since in this matter three principal classical Doctors — Scotus, Thomas, and Durant — agree, who rarely in controversies are found to be in accord.

You will object first: Aristotle (*1. de gen. T. 31.*) writes that matter is inseparable from magnitude or quantity. And (*6. Phys. T. 32.*) he laid it down first that the primary subject of motion is divisible, which cannot be unless it is quantified, and that this is matter. I add from the same place (*cap. 1.*): from what is not quantified, what is quantified does not come to be; therefore if matter were not quantified, the composite, which is made from it together with form, would not be quantified, which is evidently false. I respond to the first place: naturally indeed matter cannot subsist without quantity, nor likewise material form and the composite from both; but Aristotle there does not decide that matter is the immediate subject of quantity. To the second place: either the Philosopher speaks of the remote and not proximate subject of quantity, or — what pleases me more — he speaks not of primary matter but of secondary matter, taken for the composite, as he previously declared (*5. Phys. T. 3. & 8.*), where he treats of points, which are indivisibles with nothing actually or potentially quantified; for from what is not quantified, that is, from a point, no quantified thing comes to be, since a quantum is divisible while a point is indivisible. But matter before form and the composite, while not presupposed and preunderstood as actually quantified, is nonetheless potentially quantified and capable of quantity. And this is clear from (*1. gen. 8.*).

You will object second: the quantity of a living man is the same as that of a dead man, as the senses confirm; but the quantity of a dead man inheres in matter, because when the soul departs at death the corpse remains, which is his matter; therefore the immediate and proximate subject of quantity is matter. Confirmed: the rational soul is not quantified and has no share in quantity;

therefore the quantity of a man resides in the body, which is his matter. I concede the major and deny the minor; for when the soul withdraws, there persists the composite constituted from matter and the form of corporeity, in which quantity inheres, according to Scotus (*4. dist. 11. quest. 3. art. 2.*). To the confirmation I say that quantity is in man, who is a third thing really distinct from soul and body, just as sensations belong not to the soul nor to the body but to the whole composite (*1. anima. T. 64. & 66.*), as Durant also saw and expressed well (*praecit. ad finem quaest.*).

You will object third: for the introduction of a new form into matter, it is necessary that matter be disposed through prior accidents, among which quantity is found; therefore quantity is placed in matter. The antecedent is at hand: matter must be prepared and disposed through prior dispositions and active qualities that act to destroy the prior form and introduce a new one into the matter. I respond that matter is disposed and prepared not through accidents that are received immediately in it, but in the composite being corrupted. Hence their action does not reach matter but the composite to be corrupted, unless matter is taken for secondary matter, just as artisans are said to work in matter, which is in reality the presupposed composite — for from stone they form a statue and from wood a bench, as from pre-existing matter.

Article V. Whether the Division of Quantity into Continuous and Discrete Is the Division of a Genus into Its Species.

Many, among whom are certain disciples of Scotus — Basson (*1. dist. 24. quaest. vn.*), Paulus Scriptor (*ibid.*), Ockham (*quaest. 2.*), and the other Nominalists whom the twin Scotists follow (*disp. 7. Log. quaest. 2. art. 1.*) and Poncius (*disp. 14. quaest. 4.*) — deny that the aforesaid division is a division of a genus into its species, judging that discrete quantity is only a shadowy and analogical species of it. But Scotus (*quost. 16. praedicam. §. Ad quaest. dicendum, & quaest. 17. Et 5. Metaphysica, in com. cap. de quanto. Et eo in libro quaest. 9. Et 1. Rep. dist. 24. §. circa quaestionem*) expressly says that all agree that number is a species of discrete quantity. Mayr, Vigerius (*ibid.*), Antonius Andreas (*5. Metaphysica, quaest. 10.*), Joannes de Magistris (*cap. de quantitate quaest. 1. dub. 1.*), Tataret, Scibilis III, the Parisians, and others, to whom the Thomists also assent, affirm this to be a true and genuine partition of quantity into continuous and discrete, as of a genus into its proper species. And this is the express mind of Aristotle, both in Logic, in the chapter on quantity, and (*5. Metaphysics, cap. 13. T. 18.*), where he divides quantity into continuous and discrete. It is established thus: every genus is divided into two opposed differences that constitute two species, as I wrote (*in Log. l. 2. quaest. 2. de genere & quaest. de differentia*), where I asserted that some differences are divisive, which divide the genus, and others constitutive, which constitute the species; but quantity is truly a genus and one of the ten supreme genera, as I showed there (*l. 3. quaest. de quantitate.*); therefore continuous and discrete are proper species of quantity. Furthermore, Arithmetic is concerned with discrete

quantity as its proper subject; but every science, as its subject, respects a genus or species; since, therefore, discrete quantity is not a supreme genus but a species of the supreme genus, it is aptly deduced that it is a genuine species of quantity.

You will say: a true species of a genus is a positive entity; but discrete quantity is described through negation, since it is said to be that whose parts do not terminate upon or are joined by a common term; therefore it is not a proper species of quantity. The major being conceded, to the minor I say that through the negation a positive entity is understood, just as is signified by incorporeal and irrational, according to Aristotle (6. *Top. cap. 3. 1. de partibus cap. 3.*). You will press further: the species of a real genus are real; but discrete quantity is not real; therefore it is not a true species of quantity. The major is perspicuous. The minor is supported by the testimony of Aristotle (5. *Met. cap. 3.*): discrete quantity consists in the order of one thing to another, and order is made by the operation of the intellect; therefore, etc. I concede the major and deny the minor, as is evident from the order of the things of the world, which is true and real even when no one is thinking of it, of which Aristotle speaks (12. *Met. propè finem.*).

You will say: a species is one per se; but discrete quantity is one per accidens, for it is constituted from many complete entities, of which one has no relation to another; therefore it is not a true species of quantity. I concede the major and deny the minor; to its proof I say that there are certain material unities and one formal unity, which make one per se, as Scotus affirms (3. *d. 22. q. vn. ante §. sed quid logice L.*) — as the binary contains two material unities and one formal unity, through which it is constituted in the being of the binary; and so it is evident that discrete quantity is one per se and a true species of quantity. This will be more evident below (*quaest. 3.*).

Question II. On Continuous Quantity.

Article I. How Many Species of Continuous Quantity There Are.

The Peripatetics, in enumerating the species of continuous quantity, depart into various positions on account of the diversity of Aristotle's texts; for the Philosopher in Logic, in the chapter on quantity, lists five species of continuous quantity, which are line, surface, body, time, and place. But in (5. *Met. c. de quanto T. 18.*) he enumerates only line, surface, body, and adds weight and also motion.

First assertion: neither place nor weight is a species of continuous quantity. This assertion is twofold. The first part is handed down by the Doctor (9. 23. *praedicam. §. Ad 2. quaesitum. Et 5. Met. q. 9.*), against Mastius (*disp. de quantitate sect. 3. q. 4.*), and by Albertus (*tract. 5. praedicam. c. 5.*). It is established first: place, from (4. *Phys. T. 30.*), is the surface of the containing body; therefore place does not constitute a species of quantity distinct from surface. Second: place formally

taken, according to Scotus (*Quol. 11. art. 3.*), is a relation externally arriving, of the containing body to the contained; but quantity belongs to the genus of absolute things; therefore place formally speaking is not a species of quantity. The second part is derived from the same Doctor (*cit. in expositione Tex.*), against Simplicius and others. It is proved: weight is equivalent to a heaviness propelling a body downward to which it is attached; but heaviness is by the common opinion of Philosophers placed in the category of quality; therefore weight does not exist as a species of continuous quantity. Furthermore, weight consists in intensity, while quantity consists in extension; but gradual intensity belongs to the predicament of quality. And sometimes things of the same quantity are of different weight, as is clear from gold, which if it possesses the same quantity as silver or another metal, is nonetheless of greater weight; therefore weight is placed in intensity, which pertains to quality.

Second assertion: three species of permanent continuous quantity are enumerated: line, surface, and body. This is defended by the Doctor (9. 17. *praedicam. §. Ad 9. dicendum. Et 5. Met. in com. c. 13.*), following Aristotle in both places, against Durant (2. d. 2. q. 4.) and Hurtado (*disp. 13. Met. sect. 6.*). It is proved: the essence of quantity is the extension of parts; but only a threefold extension of parts is found; therefore there are also three species of permanent continuous quantity. The major is evident from the definition of quantity. The minor is at hand: extension of parts is either only in respect of length, and it is a line; or in respect of breadth together with length, and it is a surface; or in respect of depth together with length and breadth, and it is a body. Second: every genus possesses its species, of which it is essentially predicated, as is clear from its definition; but continuous quantity is a subalternate genus, as is evident in Logic; therefore its species, which are the three enumerated, are to be assigned to it.

Third assertion: motion and time are proper species of successive continuous quantity. The Doctor implies this (9. 23. *praedicam. §. Ad 1. arg. primae q.*) and expressly defends it (5. *Met. q. 9. §. Concedo ergo quod formaliter sunt quanta à seipsis.*). Antonius Andreas follows (*both in Log. c. alleg. and 5. Met. q. 10. §. Respondeo.*), Joannes de Magistris, Tataret, and others, against Mastrius (*disp. 7. Log. q. 2. art. 2.*) and Poncius (*disp. 14. q. 5.*), as well as Suarez (*disp. 40. Met. sect. 3. q. 9.*). It is proved first from Aristotle in the passage cited, who divides continuous quantity into permanent and successive, assigning line, surface, and body as species of the former and motion and time of the latter. Suarez responds (*moz. alleg. sect. 9. n. 13.*) by denying successive quantity and judging all quantity to be permanent. On the contrary: not only does this response conflict with the testimony of the Philosopher just adduced, but it also contradicts reason; for every being is either permanent or successive, and each participates in its proper extension and measure; but extension and measure pertain to the predicament of quantity; therefore if Suarez does not deny permanent quantity, neither ought he to reject successive quantity. Fonseca (5. *Met. cap. 13. quaest. 8.*

sect. 3.) indeed admits successive quantity, but thinks that succession belongs to motion and time not as an essential difference but as its property. On the contrary: that by which something is constituted and essentially distinguished from another is its intrinsic and essential difference; but through succession, successive quantity is constituted and distinguished from permanent quantity, since continuous quantity is well divided into permanent and successive as a genus into its species; therefore succession belongs to it in the first mode of saying per se, not in the second mode. Aristotle implies this (*3. Phys.*) when he writes that motion belongs to the genus of continua. For since the continuum is a subalternate genus of quantity, it is aptly distributed into permanent and successive as into its species. Proved second: distinct extension of parts argues a distinct species of quantity; but motion and time have extensions of parts distinct both from each other and from magnitude, in which motion is produced and of which it is the measure; therefore motion and time are distinct species of quantity. The major is evident, for the same thing is the distinguishing and constitutive principle of a thing. The minor is shown: the parts of motion and time are flowing, prior and posterior, and never simultaneously exist, since they belong to the genus of successive things; but the parts of magnitude all exist simultaneously, since they belong to the genus of permanent things. To this argument, adduced by the Doctor in the Metaphysics in the passage recalled, two of our junior authors respond by saying that motion and time only add a new mode of extension to the parts of magnitude, opposed to permanence, insofar as its parts simultaneously persist while their parts continuously flow away. And they say this succession arises both from the imperfection of the agent unable to simultaneously induce the whole term and from the contrary resisting, by reason of which in the patient a form cannot simultaneously be introduced. On the contrary: not only do these authors conflict with Scotus, who in the passage cited plainly shows through that argument that motion and time are genuine species of quantity, but in their response they also involve a contradiction by affirming that motion and time add a new extension to the parts of magnitude; for then they also add a new quantity, since extension is the reason and essence of quantity. Furthermore, succession is of the essence of motion not absolutely taken, but of continuous motion; for continuous motion cannot be produced through a medium already traversed without succession. Hence Aristotle rightly says (*3. Phys. 1.*) that motion belongs to the genus of continua; and accordingly motion and time are not to be exempted from among the true species of quantity. Proved third: where there is a property, there is the essence from which it emanates, and a distinct property argues a distinct species; but in motion and time there is a property of quantity, namely greater and lesser, equal or unequal; therefore there is also quantity. Indeed, the property of motion is different from the property of time. For in an equal space a faster or slower motion can occur, and a shorter or longer time, and the continuity of motion is usually great when that of time is small; therefore motion and time are distinct species of successive quantity.

Suarez replies (*cit. sect. 9. num. 11.*) by saying that time is twofold: extrinsic and universal, by which the motion of the first movable and of all lower things is measured, and he concedes the argument for this; and intrinsic and particular, and he thinks the argument does not apply to this. For he says that in a fast motion I move the same mobile in the same time as in a slow motion, because in both the same parts are to be traversed, and he exemplifies with heating as eight, whether fast or slow. On the contrary: the ratio is plainly the same for both kinds of time, even though one is universal and the other particular. For each measures its own motion, of which it is the measure — the former the universal motion, the latter the particular; therefore the aforesaid distinction is irrelevant to dissolving the said argument. For the same mobile through an equal space can be moved more swiftly or more slowly, and according to its motion it is measured by short or long time. Moreover, the example of heating is to the opposite. For if heating as eight is produced more swiftly, it is measured by a short time; if more slowly, by a long time, because its parts or grades can be acquired swiftly or slowly, and accordingly its motion can be fast or slow. Moreover, setting aside the universal and extrinsic time, if an eagle were to fly with the swiftest motion from east to west in the space of one day, there would indeed be a great continuity of motion, but the eagle's own proper duration and intrinsic time would be short; therefore the argument applies to both kinds of time. Fourth: a continuum is defined as that whose parts are joined by a common term; but the parts of magnitude are joined by a point, the parts of motion by a thing that has been changed, and the parts of time by an instant; therefore since the termini of these quantities are distinguished, the quantities themselves also differ from one another. Mastrius responds with his colleague (*ubi supra*), using the distinction of Suarez just adduced, conceding this of extrinsic time but not of intrinsic time, which he judges to coincide with motion. On the contrary: the common ratio of time is univocated to both kinds of time, as Antonius Andreas notes (*5. Met. quaest. 11.*) following Scotus (*ibid. q. 10.*); for each is a measure of motion, has parts outside of parts, not simultaneously but successively; therefore it participates in a common term, which is the instant, just as magnitude, whether common or particular, has a point, and motion has a thing that has been changed. Again: distinct species of one genus have distinct differences and properties, as is clear by the rule before the predicaments; but motion and time are distinct species of successive continuous quantity, as the Doctor clearly sets out in the passage now cited not far from the beginning of his question; therefore they do not share the same indivisible parts and termini, as the authors named contend.

You will object first, against the first assertion: Aristotle (*cap. de quantitate*) places place among the species of continuous quantity. And (*5. Met. cap. de quanto*) he omits place and posits weight. The common reason is that each participates in the chief property of quantity, in terms of which both place and weight are said to be equal or unequal; therefore they are referred to in the list of species of

quantity. I respond that Aristotle there spoke not in his own but in another's position. For as his interpreters note, at that time there was a certain popular and well-known opinion listing place in the number of species of quantity, although it is not distinguished from surface, in terms of which it is said to be equal or unequal. Weight, however, is called equal or unequal not because it is a species of quantity but by reason of the quantity joined to it; in reality, however, it belongs to quality, for since it is heavy or light, which is the proper characteristic of quality, it is to be reduced to quality.

You will object second, against the second assertion: one species of one genus is not ordered to constituting another species of the same genus, because every infima species is complete and perfect; but line is ordered to constituting surface, for surface is made from length and breadth; and surface and line enter into body, which consists of the triple dimension of length, breadth, and depth; therefore line, surface, and body are not proper species of permanent quantity. I distinguish the major: formally, I concede it; materially, I deny it. For from the binary the ternary is made, and from the ternary the quaternary, and each is a species of number. Likewise, an organic body is a species of substance even though it is ordered to receiving the soul and constituting an animate composite, which falls under the genus of substance.

You will object third, against the third assertion: Aristotle (*5. Met. c. 13.*) and Scotus (*ibid.*) assert that motion and time are *quanta per accidens*; therefore motion and time are not true species of quantity, which are *quanta per se*. I respond by expounding the testimony of Aristotle: *quantum per accidens* is twofold — one that lacks extension and is extended through the extension of another, as what is white is quantified; for whiteness of itself participates in no extension but borrows it from quantity, hence what is white is said to be *quantum per accidens*. The other indeed has its own extension but is made through another, as surface through line and body through surface are made quantified; in this way time is said to be *quantum per accidens*, because its quantity is produced by motion and the quantity of motion by magnitude, as Scotus rightly interprets (*eo in loco q. 9. & 10.*), Antonius Andreas (*both in Log. in exp. c. de quantitate and 5. Met. q. 10.*), Thomas, Fonseca, and others there, whatever the recent Scotists named above may say.

Article II. Whether in a Continuum There Are Real Positive Indivisibles.

Many, among whom are numbered Ockham (*in praedicam. quantitatis, Tract. de Euch. cap. 1. & 2. Et Quol. 1. quaest. 9.*), Mayr (*1. d. 24. quaest. 1.*), Durant (*2. d. 2. quest. 4.*), Pererius (*10. Phys. cap. 6.*), Aversa (*quaest. 22. sect. 4.*), and Gregory (*2. d. 2. quaest. 2. art. 1.*), deny that there are real positive indivisibles in a continuum, and if there are any, they are negative and apprehended through imagination. They say that a point is the negation of length, a line the negation of breadth, and a surface the negation of depth. Others, such as Fonseca (*5. Met. c. 16. q. 6.*), admit

positive indivisibles that terminate but reject those that continue. The others, such as Scotus (2. d. 2. quaest. 9. §. *Ad argumenta quaest. T.*), Lychetus (*ibid.*), Tataret, both there and in Logic in the chapter on quantity (*dub. 2.*), the Parisians (6. *Phys. quaest. 1.*), the Complutenses (*disp. 24. quest. 1. §. 2.*), and others cited by them, assert that in a continuum both continuing and terminating real positive indivisibles are to be posited.

Note that an indivisible is described as that which lacks entitative or quantitative parts. There is a twofold indivisible: one substantial and another quantitative. The substantial indivisible lacks entitative parts, of which kind are the Angel and the rational soul. The quantitative indivisible lacks quantified parts, commonly called integral, such as a point in a line, an instant in time, and a thing changed in motion. A point, moreover, is found to be twofold: one that terminates continuous quantity, such as the last point of a line, and another that continues, joining the parts of continuous quantity. For the continuum is that whose parts are joined by a common term, and the contiguous is that whose extremities are together or in the same place, as can be seen (5. *Phys. T. 26. 6. eiusdem operis, T. 1.*).

First assertion: points, whether terminating or continuing, are real positive entities. The Doctor holds this (*passim praealleg.*) from Aristotle as now cited and (5. *Met. cap. 6.*). It is proved first from Augustine (1. *de quantitate animae, C. 11. Et 12.*), where in explicit words he says: "From it (that is, a point) a line begins and is terminated by it, and we see that no figure formed by straight lines can be made unless the angle is closed by it." And after a few words he adds: "No line is joined to a line except through it." Where it is openly evident that the holy Doctor teaches that real positive continuing and terminating points exist in a continuum. I know that this testimony of Augustine is adduced by Mayr in the passage named above for the opposing position. For Mayr judges that Augustine admits indivisibles in the continuum that are imaginary and conceived by our mind, but not real and positive. But even if the holy Augustine there contemplates indivisibles in the mathematical manner, as is evident from cap. 10 of the said book and from what follows — which the mathematical figures drawn by him also make manifest — and in (7. *de genesi ad lit. cap. 17.*) he shows the same thing: nonetheless he does not deny them to be positive and to be viewed physically, since he asserts that through them a line begins and ends and its parts are joined and continued, as his words which we cited above make manifest. Second: a continuum, from the chapter on quantity, is defined as that whose parts are joined by a common term, which in all opinions is a point; but the parts of any whole are not joined to a negation or privation but to a real positive entity, just as the parts themselves are real and positive; therefore since the parts of a continuum are united by a point, it is evidently shown that the point is a real positive entity. Fonseca responds (5. *Metaphysica, cap. 13. quest. 6. sect. 5.*) that there is plainly no point in act in a continuum by which its parts are simultaneously joined, since they are joined by themselves and cohere among themselves; but the said parts are fictitiously said to be joined by points, so that

these may be certain signs for making divisions of parts to infinity. On the contrary: what is placed in the definition of a real positive entity is a real positive entity, not something fabricated and made by the mind, as the Doctor clearly sets out (*4. distinct. 1. quaest. 2. §. Hic primo. B.*); but a point is placed in the definition of a continuum, expressed through the common term; therefore in truth a point exists in the continuum. Furthermore (*6. Physic. 1.*), Aristotle investigates whether the continuum is composed of points; but what composes some whole actually exists in it, just as matter and form, which constitute a whole, actually exist in it; since, therefore, the Philosopher presupposes that there are points in the continuum and asks whether it consists of them, he undoubtedly wants points to actually exist in the continuum. And that they are not fabricated, because no fabrications pertain to the construction and composition of any real whole. Finally: the terminus of a real positive entity is a real positive entity; for a positive entity is not terminated by negation, privation, or fabrication — as a being is, so too is its terminus; but the continuum is a real positive entity, since it is an accident and a species of the real genus of quantity; therefore its terminus, which is the point, is a real positive entity. Durant responds in the passage mentioned above, saying that the instance has no force because the continuum is not ended or terminated by a point but by itself; for what is ended and terminated is ended and terminated by itself and not by something extrinsic to it, such as a point. On the contrary: this response conflicts with Augustine in the passage cited, who admits positive continuing and terminating points; it conflicts also with the Philosopher, who posits that points are moved by the motion of the thing in which they exist (*6. Phys. cap. 9. T. 86.*) and that they have a position in the continuum (*1. animae cap. 4. T. 70.*), and that a perfectly spherical body touches a perfectly flat surface at a point (*3. Caeli cap. 8. T. 69.*). But motion, touch, and things of this kind belong only to a positive entity. It also conflicts with reason: a point is placed in the definition of a line, as is evident from Euclid (*1. Elem.*): "A line is a length without breadth and depth, whose extremities are two points." In the definition of a positive entity such as a line, only a positive entity is placed, as the Doctor signifies (*4. dist. 1. quaest. 2.*). Furthermore, a positive divisible, such as the continuum, is not terminated except by an indivisible. For such is the nature of continuous quantity, whose parts are joined by an indivisible and likewise ended and terminated by an indivisible.

You will say: Aristotle (*3. Phys. T. 31.*) writes that what is finite is not ended by another but by itself; therefore the continuum, which is finite, has no terminus that is a point. On the contrary: the Stagirite there treats not of the proper terminus of the continuum but of an alien and extrinsic terminus, as Toledo and the Conimbricenses rightly interpret — as if the earth is terminated by water, and water by air, and so on, the Philosopher says that if one thing must always be terminated to another, there would be no terminus. Third: just as an instant is to time and a thing changed is to motion, so a point is to the continuum; but

an instant in time and a thing changed in motion are real positive entities; therefore a point is also real and positive. Durant responds in the passage cited above by conceding the major and denying the minor, since a thing changed is not an indivisible intrinsic to or adjoined to motion, but a privation of further continuation in motion; and if time were to end, its instant would be an absence of further continuation. On the contrary: time is the measure of motion (*4. Phys. T. 101.*) and they are the same in reality, as the same author hands down there. But an instant of time, according to him, is not a privation of further duration; therefore neither is a thing changed a privation of further continuation in motion. For as time is continuous, so motion is continuous, since the former is the measure of the latter. Moreover, certain things endure through an instant, such as generation and illumination; therefore an instant of time is a real positive entity. For it would be inconvenient for positive momentary entities to have a duration that is a privation or negation, while others endure with a real positive duration.

Second assertion: the other indivisibles — a line with respect to breadth, and a surface with respect to depth — are real and positive. The Doctor gives patronage to this (*2. dist. 2. quaest. 9.*), and it is established first from Aristotle (*1. praedicam. cap. de quantitate, Et 5. Met. cap. 13.*) and Scotus there, and others who commonly treat of the aforesaid as of real positive entities. Second: the species of a real positive genus are real and positive. For a species does not depart from the genus of which it is a species; but line and surface are species of the genus of continuous quantity, as I proved (*art. 1. huius q. aff. 2.*); therefore they are real positive entities. Third: unless the aforesaid indivisibles were species of continuous quantity, there would be only one species of it, namely body; but one genus has at least two species constituted by two opposed differences into which the genus is divided, as I showed elsewhere. Fourth: the objects of real sciences are real, because real sciences are named from real objects; but line and surface are objects of real sciences, namely Geometry and Optics. Moreover, certain qualities inhere only in a surface, such as figure (*3. Met. 17.*); but the subject of a real positive entity is real and positive; since, therefore, a surface is established as the subject of real qualities, it plainly follows that it is real and positive.

You will object first: three principal testimonies from Aristotle, of which the first is from (*8. Phys. T. 68.*): points are not in the continuum in act but in potency. The second is from (*3. Met. T. 17.*): a surface is in a solid as Mercury is in rough stone; but evidently the figure of Mercury is in rough stone only in potency; therefore the same is to be asserted of a surface and a point, that they are in the continuum in potency. The third is written (*3. anima T. 25.*): a point is known through privation; therefore points and the other indivisibles in the school of Aristotle are not real positive entities. I expound the first two places through a distinction: indivisibles are in the continuum in potency with respect to existence — I deny this, for they truly exist in it, just as its parts, and no one

doubts that the parts actually exist in the continuum; with respect to division — I concede. For just as the parts of the same are said to be in it in potency, because they are not actually divided and distributed, so too are points and the other indivisibles said to be in the same in potency, because they are not actually divided. So Bonet (*libel. de quantitate*) satisfies this, and Suarez (*disp. 40. Met. Sect. 5. n. 34.*) and other recent authors follow him. To the third I say that certain positive things are known through negation or privation, as Aristotle exemplifies there with black, which is evidently a positive entity, and with primary matter (*7. Met. T. 8.*), and I showed of God (*tract. de cognoscibilitate Dei disp. 1.*). Therefore, although a point is known privatively, that is, through privation of length, it is nonetheless not to be excluded from among positive entities.

You will object second: the continuum is terminated by itself; therefore a point is not its terminus. The antecedent is proved by analogy: just as quality is ended by itself and not by something added to it, so quantity is ended by itself and not by a point adjoined to it. Confirmed: if God were to remove from a line the terminating points, it would surely be finite and terminated, not through points, since they are supposed to have been removed from it; therefore through itself, and consequently it is futile and vain to imagine real positive points in the continuum. I deny the antecedent; to its proof I say that there is a dissimilarity between quality and quantity. For quality does not have an intrinsic terminus in the way that continuous quantity does, as is clear from its definition, in which a terminus, which is a point, is expressly placed. To the confirmation: given that hypothesis, the line would be finite, not positively but privatively; and although it would not have an intrinsic terminus, it would nonetheless have an extrinsic terminus. Or the hypothesis is denied, because points are enclosed in the definition of a line, which perhaps Aristotle signifies (*1. post cap. 4. T. 9.*) when he writes that a line is made from points.

You will object third: every real positive entity is either substance or accident; for everything that exists either subsists per se and is substance, or inheres in a subject and is accident; but a point is not a substance, as Aristotle shows (*3. Met. cap. 6. T. 17.*), nor an accident, which requires a subject to support it; but since a point, being indivisible, participates in no proper subject with no part of material substance corresponding to it, therefore a point and any other indivisibles hold no place among positive entities. I respond that the major is not absolutely immediate and sufficient, because there can be something of substance or accident, of which kind are their properties and modes. Hence, although a point is not substance nor accident, it is nonetheless something of an accident, namely the terminus of the continuum; thus a point is said to be in the continuum as the term in the unterminated, as Mayr touches on (*passim praeominato*), and Canon assents (*6. Phys. q. 1. art. 1. §. sed contrà*), and Lychetus confirms (*2. d. 2. quaest. 9.*).

Article III. Whether a Continuum Is Composed of Indivisibles.

The opinion of Zeno, Pythagoras, Democritus, Plato, and many others who held that the continuum is composed of indivisibles flourished and was very strong. Among our own authors, Gerard Odo, the General, and Bonet (*libello secundo, de quantitate*) favor them. These, though they all agree that the continuum consists of indivisibles, nonetheless differ, for some, such as Plato, disagree in thinking that a line is composed of points, a surface of lines, and a body of surfaces; while others, such as Democritus, hold that the continuum is constituted from indivisible quantities, namely a body from indivisible corpuscles called atoms, a surface from indivisible surfaces, and a line not from points but from indivisible lines. The opposing opinion is defended by Aristotle (6. *Phys.* 1.), Scotus (2. *d.* 2. *q.* 9. *Et* 2. *Met.* *q.* 6.), Antonius Andreas (5. *Met.* *q.* 10.), and the other Philosophers commonly, who deny that the continuum consists solely of indivisibles and affirm that the continuum is made from parts divisible ad infinitum.

Note first that a twofold continuum can be conceived, as Canon observes (6. *Phys.* *q.* 1. *art.* 2.) following Scotus in the passage just cited (§. *Ad argumenta.* E.): mathematical and physical. The former abstracts from every sensible quality and other natural things; in this way the Doctor adds (4. *d.* 49. *q.* 16. §. *Ad* 1. *D.*) that mathematicians contemplate quantity purely as quantity. The latter is conjoined with sensible quality, motion, and other natural things. Moreover, the parts of a continuum are of two kinds: aliquot and proportional. The former are parts of a certain and determined quantity, which taken a given number of times complete the whole continuum, as if a whole board is divided into four equal parts, such parts are called aliquot; and by some they are called non-communicating parts, because one does not contain the other, nor is one included in the other, but each is entirely distinct from every other. The latter are unequal parts that keep a certain proportion to one another, as three is to six so six is to twelve; and they are called communicating parts, because one includes another, and one participates in the entity of another, as if a board is cut into two parts and these into others, and so on into smaller parts, there are always other parts remaining to be again divided, by reason of which the continuum is said to be divisible into always-divisible things.

Note second that some things are evident to us, such as first principles and what is perceived by the senses; while other things are nonevident, unknown and hidden to our senses, among which is the continuum, of which we treat in the present. For its composition and resolution seems so difficult to grasp that even the most outstanding intellects can scarcely attain it; nonetheless one must not draw back from its investigation. For Aristotle warns (1. *de lineis insecabilibus*), in encountering this difficulty, that it is absurd for someone to succumb out of laziness, because he does not dare to fully dissolve the arguments presented, and thus to foster his weakness and thereby deceive himself with still graver fallacies. For he had earlier laid down (8. *Phys.* *T.* 22.): it is the mark of the slow

and ignorant to cling to an apparent argument and abandon sense, from which our cognition arises.

The negative part, which is Aristotle's and Scotus's, is proved first: what are continua are those whose last things are one (6. *Physic. 1.*). But indivisibles do not have last things, because if they are terminating ones, they are themselves the last things; hence a line is described as a length whose extremities are two points. But it is one thing to be the last and another to have a last; the continuum indeed has a last but is not the last; since, therefore, those from which the continuum is composed are divided into what is last and what has a last, it is plainly deduced that the continuum is not composed of indivisibles. The proponents of the opposing opinion respond by distinguishing the major: with respect to parts composing it, they deny it; but with respect to discrete differences of situation or place or time, they concede it. And this they make manifest concerning individual indivisibles, such as the point, which existing in the middle of a square can terminate the diagonal coming from the right side without terminating the one coming from the left; and so in the point, albeit indivisible, right and left, before and behind, and similar things are assigned. Furthermore, in the surface, which is indivisible with respect to depth, it is easily shown: for it is terminated from within and without, for the body contained by a surface is within the surface and the containing body is outside its surface; in this way the surface as indivisible participates in extrinsic sides, by reason of which it is divided. Likewise concerning a thing that has been changed, which is the indivisible terminus of motion, even though a continuation of prior with subsequent motion is made. Finally, concerning an instant of time, which though indivisible, is nonetheless the end of past time and the beginning of future time, and in it the relations of beginning and end arise. To this response Canon (6. *Physic. quaest. 1. art. 1.*) presses and urges, saying that the aforesaid discrete differences of place and time either exhibit absolute or relative entities: not the first, because the indivisibles would then be divisible, insofar as they would be divided into several entities; nor the second, because several relations require several foundations in which they are grounded; therefore the said respects and situational differences cannot exist in a point. But this instance does not overturn the aforesaid foundation nor does it enervate its force; for conceding the first part of the minor, I deny the second, since in one and the same foundation several respects can exist, as in the same father there are several relations of paternity corresponding to the plurality of children begotten by him; and the parts of the continuum respect the same common term, which is the point to which they are joined, as Aristotle hands down (1. *praedicam. c. de quantitate.*). There is no inconvenience, therefore, in the indivisible obtaining the aforesaid respects. And this is especially confirmed, in the opinion of Democritus, by Augustine (2. *de lib. arb. c. 8.*): "However small that corpuscle is, it certainly has one part right, another left, another above, another below, another farther, another nearer, or other terminal parts." Second: what

compose the continuum touch one another with the touch of continuity; otherwise it would not be a continuum but a discrete thing; but indivisibles do not touch one another according to the whole, otherwise they would not make anything larger, nor according to a part, since they lack parts; therefore the continuum does not coalesce from indivisibles. The authors named above respond by conceding the major and distinguishing the minor: indivisibles, such as points, do not touch one another externally — they concede; they do not touch one another externally — they deny. For they touch one another with respect to extrinsic sides, so much so that with respect to one side they touch each other and not with respect to another, because one point is next to another adjacent to it. You will say that such discrete differences belong to a body in the parts of which the fundamental reasons of these differences are found, but not to the indivisible, which lacking parts cannot be their foundation. On the contrary: although they are properly accommodated to an animate body, and metaphorically to an inanimate one, as is evident from the heaven, nonetheless they are also adapted in their own way to the indivisible. For a point existing in the middle of a circle respects east, west, south, and north, the right and left side, and similar things; just as also an Angel, though indivisible and existing in a city, can look toward the said positions. Indeed, Aristotle in the definition of the continuum places a point, which respects, unites, and joins all its parts; therefore the aforesaid relations are not to be denied to the indivisible. Third: let a continuum consisting of three points be traversed by two mobiles, of which one is double the speed of the other and the other double the slowness; given this hypothesis, the faster mobile will traverse it in three instants of time, while the slower will traverse the same in one and a half instants; therefore from the position of Zeno and the others it follows that the indivisible is divisible; but this is impossible; therefore the Stoic assertion is also false and improbable. The proponents of the contrary opinion go to meet this and deny the consequence. For even if division can be effected according to the said differences, it cannot according to indivisibles, since they lack parts. Hence I deny that the transit will be in one and a half instants, since both the instant of time and the point of space to be traversed are impartible and indivisible. You will say: then the slow mobile will traverse one and the same space equally quickly as the fast mobile. The consequence is denied; for the faster will complete its course more swiftly than the slower mobile, yet the indivisible will not be divided on account of the repugnance it exhibits, just as the impossible cannot be made, so the indivisible cannot be divided. Fourth, it is established from Scotus in the passage cited: a smaller circle cannot be equal to the larger circle in which it is contained, as is seen with the eyes by drawing the said circles; but given the doctrine of Zeno, the smaller circle would be equal to the larger. For if from the circumference of the larger circle two lines are drawn tending toward the center of the smaller circle, or conversely from the center of the smaller circle to the larger, those lines passing through the smaller circle cut the smaller circle in one point or in two; not the first, otherwise the indivisible would be divided and the total angle

would be made equal to the partial angle, and two parallel lines would converge into one, which does not appear, since in their progress they recede further from each other. Nor the second, for otherwise there would be as many points in the smaller as in the larger circle, and so a part would be equal to the whole and the lesser to the greater, which conflicts with that common and true axiom: every whole is greater than its part. Bonet responds together with Gerard in the passage cited, by conceding the major and denying the minor; for given the hypothesis, though the said lines with respect to the intercepted space would be equalized, they would not be with respect to the rest, for they would be superimposed upon the smaller circle, as in a narrower and smaller container, as is seen in other similar things. And as for what is added about parallel lines, I say that this applies to disjunct and distant ones, not to superimposed ones, as occurs in the smaller circle. Fifth: the diameter of a square would be equal to the side, which conflicts with the senses. For if two lines are drawn from one side to the other side, either they cut the diametrical line in one point or in two; not in one, otherwise the side would be larger than the diameter, since one point of the side would correspond to only one point of the diameter; nor in two, otherwise the side would be measured by the diameter, insofar as it would have as many points as the diameter, and the distance between one side and another would be the same as the distance between one angle of the diameter and the other angle, which is plainly false. The consequence is denied by the authors named above: just as the larger circle has more parts and points than the smaller, as was concluded in the response to the preceding argument, so the longer line, such as the diametrical line, contains more points than the shorter line, such as the lateral line. Hence Arriaga says (*disp. 16. Phys. sect. 8. subsect. 5.*) that the diameter has certain points remaining at its sides, by reason of the position of the diameter; and therefore necessarily a line drawn from one side to the other side sometimes traverses two of its points. Sixth: the opposing opinion is numbered among the errors of John Hus condemned at the Council of Constance, as can be seen (*fols. 12.*). In addition, Augustine (*lib. de quantitate animae, cap. 11. 12.*) seems to embrace this doctrine of Aristotle about the composition of the continuum; therefore the contrary, which is the Stoics', conflicts with and contradicts the definition of the Holy Church and the authority of the Fathers, notably Augustine as now cited. One can respond that the mind of that Council was not to condemn the position of Zeno and other Philosophers about the composition of the continuum, which does not conflict with Orthodox faith and good morals. Especially because, as Arriaga attests, in the whole body of the Council the said opinion is found not except in a certain appendix, from a codex of a certain Canon of Cologne, which the Typographer testifies to be corrupt. Nor in any other preceding or subsequent Council is there mention of it. Hence Lychetus (*2. distinct. 2. quaest. 9.*) affirms that in his time many defended the said assertion, nor even now are there lacking those who defend it as a problem resting on solid foundations and fortified by effective arguments, as will be evident below. To Augustine I say that he does not expressly hold this,

since he seems to think that points are not real positive entities, as Mayr notes (*1. dist. 24. quest. 1.*). Furthermore, if he hands down that the points of a line are positive and that the line is terminated by them, nonetheless whether the continuum coalesces from indivisibles or not, he utters not a word for either side. I add that Augustine for the most part favors Plato, whose doctrine this is, more than Aristotle, who nearly in all things, not so much by reason as by will, strove to contradict him, as Bonet in the passage cited and Mayr (*1. distinct. 47. quaest. 3. art. 2.*) above all testify. Which Plato perhaps signifies in Fonseca (*1. Met. cap. 1.*) when he says: "Aristotle recalcitrates against us, just as puppies against the mother who bore them."

The affirmative part, which is Zeno's, Plato's, and the other ancients', is established first and urged first against the negative part, from (*1. Post. cap. 4.*): a line consists of points. And (*7. Met. T. 32.*): the parts of the defined are placed in the definition of it; since, therefore, a point is placed in the definition of a line, as is evident from Euclid (*1. elem.*) and Aristotle (*1. gen. 8. 9.*), it is clearly shown that a line is composed of points, and anything else that is continuous is made from indivisibles, even in the school of Aristotle. One can respond in two ways: first, that the Philosopher speaks in those places in the opinion of others; for in (*6. Phys.*) he expressly and consistently refutes those who think that the continuum consists of indivisibles; and that is the proper place for examining and deciding this controversy and adhering to one side. Second, it can be said that a point is placed in the definition of a line not as a part but as a bond or terminus of it, just as a subject is placed in the definition of an accident as something added and extrinsic.

You will object second: as one is to number, so a point is to a line (*1. Top. cap. 14.*); but a number is constituted from units; therefore a line is also composed of points. A ready and obvious response is available if one says that the parity of one and a point consists in this: just as one is the principle of number, so a point is the beginning and terminus of a line; but there is a disparity, because one is a part of number, while a point is not a part of a line.

You will object third: if a perfectly spherical body is rolled over a perfectly flat surface, it will describe a line composed of points; therefore a continuum consists of indivisibles. The antecedent is Aristotle's (*1. anima T. 13.*): a spherical body touches a flat surface at a point, as Scotus also maintains (*3. Met. ante expositionem, cap. 2.*). And mathematicians say that a line is the flux of a point, a surface of a line, and a body of a surface, which the Stagirite indicates (*1. Caeli T. 4.*) and Averroes explains (*3. Phys. comm. 60.*). The response is that, granted the hypothesis, a spherical body would indeed touch the flat surface at a point; but it is denied that a line would thereby be composed of points. For after a point there follows a part of a line, as the Doctor writes (*2. Met. quaest. 7.*); just as after an instant there follows a part of time (*2. distinct. 2. quest. 9.*). Nor does it seem inconvenient, Mayr adds (*2. distinct. 2. quaest. 12.*), for an indivisible to touch a

part in flux and as it were in the manner of the way, just as a burning coal swiftly moved back and forth between both hands burns neither, which it surely would if it were to remain in either. To what is added about the flux of a point, surface, and body, I say that mathematicians merely indicate to us the flowing and continuity of the parts of the continuum, but do not think that the continuum itself consists of indivisibles.

You will object fourth: points are proximately and immediately next to one another; therefore a line is made from points. The antecedent is shown: if two boards joined together immediately touch each other, their points immediately touch each other; therefore points are proximately and immediately next to one another. The Doctor satisfies this (*11. Met. concl. 67.*): in the same continuum, between two points there falls a part of a line, just as between two instants a part of time is interposed. To the proof I say that this applies in different and distinct continua, such as two boards joined together, but not in the same continuum, of which there is now the difficulty.

Article IV. Whether a Continuum Is Divided into Always-Divisible Things.

The solution of the present difficulty depends on the decision of the preceding article. For those who affirm that the continuum coalesces from indivisibles alone consequently assert that the continuum is divided into certain, determinate, and finite indivisibles; while those who deny that the continuum is composed from indivisibles alone must hold that the continuum is divided into always-divisible, uncertain, and indeterminate things.

Note first that in the present question there is no doubt about aliquot parts, but about proportional ones. For the former, since they are of equal quantity, are determined by a certain number; but the latter, since they are unequal, are not confined to any certain limit and number; and therefore they are said to be infinite in potency and finite toward infinity, so that neither the first nor the last can be found; but if such parts are divided, there are always others remaining to be divided and others again to be taken.

Note second that something can be infinite in two ways: first in act, which others call infinite in accomplished being and in accepted being, whose accepted things are so many that no more can be accepted — in this way a line is said to be infinite, to which nothing can be added, and so Aristotle (*3. Phys. T. 24.*) shows that an infinite body cannot be given. Second, in potency, which others call infinite in becoming and in accepting, from which if more are accepted, more remain to be accepted ad infinitum, so that there is no limit and no terminus to them. Furthermore, observe that divisible does not denote act but potency. For divisible means the same as what can be divided, and so the continuum does not have parts in accomplished being that constitute an actual infinite, but in the accepting of one after another, which make an infinite in potency.

Note third that there are as many ways of saying something is in potency as in act. Something is in potency in two ways. One way in objective potency: what does not exist but can exist, is in objective potency and in the power of the producing cause; in this way creatures were in the potency of God before they were created. Another way in indeterminate and indistinct potency, which is equivalent to not having distinct and determinate being from another; in this way a genus is said to have its species in potency, and a homogeneous whole its parts, because they are confused and indistinct. In the first way, to be in act is the same as to exist, so that whatever exists is in act. In the second way, to be in act means to have distinct and separate being from another, so that it exists and subsists with its own existence and subsistence. Hence, although parts exist in the continuum, they are nonetheless said not to subsist and to be in act but in potency, because they are not mutually disjoined and separated; for act distinguishes and separates, as Canon (6. *Phys. quaest. 1. art. 2.*) deduces from (7. *Met. T. 49.*) and Scotus explains.

The affirmative part — that a continuum is divided into always-divisible things — which is Aristotle's and Scotus's as cited in the preceding article, is proved first: a thing is divided into those from which it is composed; but the continuum is composed of always-divisible things; therefore it is divided into always-divisible things. The major is common and well-known; for as a human being is composed of soul and body, so it is divided into body and soul. The minor was shown in the preceding article. To this, the proponents of the contrary opinion respond by denying the minor, positing that the continuum consists of indivisibles. With the same ease that proposition is proposed, it is refuted by the same. Second: the parts of the continuum are either divisible or indivisible, because between divisible and indivisible there is no middle; but they are not indivisible, because they are quantified, and every quantum is divisible, since divisibility is a property of quantity; therefore they are divisible, and consequently the continuum is divisible into always-divisible things. For there is no greater reason why some parts should be divisible and not others, since they are of the same nature; therefore any given part can be cut into other parts, and so on ad infinitum. The adversaries go to meet this and say that some are divisible and others indivisible, so that there is a last part in the division of the continuum that is indivisible and inseparable, as will be plain below.

The negative part — which is that of the ancient Philosophers and certain moderns, that the continuum does not coalesce from divisible things and is not divisible into always-divisible things — is shown first: if the continuum were divisible into always-divisible things, it would consist of infinite parts, because the infinite is not divisible into finite parts, otherwise it would be finite, for what is finited is finite; but what has infinite parts is infinite; but the infinite is not given (3. *Phys. T. 35. & inde*); therefore the continuum is not divisible ad infinitum. The response according to Aristotle is through the distinction of the major: the continuum is constituted of infinite parts in potency — this is

conceded; in act — this is denied. On the contrary: the parts into which the continuum can be cut actually exist in it, for they truly exist in it, as is evident (5. *Met. cap. 13. & alibi non semel*); a quantum is divisible into what is present in it; therefore its parts are actually infinite and not just potentially. One can satisfy this if it is said, from the notable second and third observations placed above, that these parts are in the process of dividing, because the continuum is divisible and not yet divided. Hence just as its parts are not divided but divisible, so they are said to be not in it in act but in potency. This response is indicated by Augustine (2. *de libero arbitrio, cap. 8.*) and therefore is not to be despised. Second: given the hypothesis, no one could ever divide the continuum into its last parts; indeed, a leaf of a tree could not be divided by an Angel into all its parts in all eternity, which seems not only incredible but impossible to all, and absurd and a great incongruity; therefore the aforesaid division of the continuum into parts divisible ad infinitum is fabricated and imaginary. Mastrius goes to meet this (*disp. 6. Phys. quaest. 2. art. 6. ad finem*), saying there is no inconvenience, because although the senses cannot perceive this, the intellect nonetheless grasps it well, since a quantum is always divisible, which is demonstrated physically and mathematically. On the contrary: this conflicts openly with sense and intellect; for every finite thing, such as the continuum, is eventually ended and consumed by the removal of parts; therefore when it is said that the continuum is divisible into always-divisible things, this is true only up to the point where the smallest parts are reached. This seems to be scented, though with difficulty, by Toledo (6. *Phys. in T. 23.*), who says he does not understand this of real division but of a division of reason — which is to say, there is no quantity in which we cannot conceive by the intellect two or more parts separated in situation, and so on ad infinitum. Therefore such a partition of the parts of the continuum ad infinitum seems futile and vain, being as it is one that can never be achieved by any being, created or uncreated. Third: God knows distinctly all the parts into which the continuum is divisible, since nothing is hidden from him (*Hebr. 4.*): "All things are naked and open to his eyes"; therefore he knows the last parts into which the continuum can be divided, and thus the continuum is eventually ended by the last parts. The antecedent is conceded and the consequence is denied. For God knows things as they are, and because in the continuum there are no last parts, they are therefore not known by God; just as God knows the parts of time, not indeed permanent — for there are no permanent parts in it — but flowing, because they are in perpetual flux; so God knows the parts of the continuum not as inseparable, but as separable and divisible ad infinitum. Against this: "The Lord has disposed all things in measure and number and weight" (*Sapientia 11.*); therefore the parts of the continuum are finite in number, since they are among the things God made, which are finite in multitude and greatness. And consequently last impartible and inseparable parts are to be admitted in the continuum. Fourth: from the position of Aristotle, no motion of a mobile in a space would occur, which contradicts experience; therefore such parts are not

given in the continuum. The consequence of the antecedent is proved: a mobile traverses the prior parts of a space before the posterior ones, as is seen with the eyes; but in the opinion of Aristotle there are no prior and posterior parts, but infinite ones, and infinite things cannot be traversed; therefore a mobile that really moves through a space cannot move, since it cannot traverse the parts that are infinite in the continuum. The consequence of the antecedent is denied; to its proof I say that a mobile through motion traverses an extended space, which is required so that the mobile completes its motion; but whether that space consists of aliquot and proportional parts finite or infinite in number, this has no bearing on the notion of motion, just as motion occurs over the sand of the sea, though it cannot be numbered; so too a bird moves through the air in flight, because it is extended, even though it is thin and constituted from minute parts, which do not pertain to the motion but do pertain to the air itself and its extension. Fifth: in every order of essential dependence there is a terminus at some independent and first thing in that order, as Aristotle demonstrates (*2. Met. cap. 2.*); otherwise there would be a process to infinity, which is to be avoided by one who philosophizes rightly; but the whole continuum essentially depends upon its halves, just as the composite depends upon matter and form; and those halves upon these, those upon others, and so on consequently up to the last, which is impartible and indivisible. Nor does it help to say with Canon in the passage cited that the major applies in extrinsic causes but not in intrinsic causes. For Aristotle in the passage now cited proves it in every genus of causes, and the subtle Doctor explains it there. And this is also evident from relations, of which if one grounds another, one nonetheless arrives at the last one, which is not a ground of another; nor is a line such unless closed by two points, as is clear from its definition cited from Euclid (*1. Element.*). Hence it is not surprising if those who think otherwise, pressed by the greatest difficulties and bowed down by the most weighty arguments, fall into unheard-of inconveniencies and enormous absurdities, and are entangled in various contradictions, which they frankly confess they cannot truly and fully resolve — as Aristotle (*lib. de lineis insect.*), Toledo, Mastrius, and others who tenaciously follow that position acknowledge. For they are necessarily forced to admit an actual infinity of multitude, namely infinite points in a line, and actually infinite parts in any continuum, which they plainly deny elsewhere in fact. Again, they are necessarily forced to deny the common and true axiom: a power is useless that is not reduced to act, since according to them the act of the last division of parts is in no way reached in the continuum. Moreover, they are compelled to reject the evident maxim that the whole is greater than its part, when they assert that a human hair has as many parts as the whole human being, indeed as the whole universe; and many other incredible and perhaps impossible things, which it is tiresome to enumerate. I add that they greatly depress the created intellect and diminish the power of God, which could not bring out the parts of one act in all eternity, nor find the first or last of them, when he himself has founded them all and joined them together simultaneously in the continuum.

Question III. On Discrete Quantity.

I showed in the preceding question that discrete quantity is a true and genuine species of quantity; now it must be investigated what the species of discrete quantity are. For since discrete quantity is a subalternate genus, its species — which are said to be number and speech — are examined in the present.

Article I. Whether Number Is a Real or Rational Being.

Those who do not count number among the genuine species of quantity, whom I cited (*in prima quest. huius lib. art. 5.*), place number formally taken among beings of reason; while those who teach that number is a genuine species of discrete quantity consequently assert that number is a real being.

Note, from (*4. Phys. cap. 12.*), that number is distributed into numbering number and numbered number. The former is the act of the intellect counting what are numerable, as when a General numbers the soldiers of his army; the latter is the thing itself that is counted, such as soldiers counted by their general.

Furthermore, number is divided into material and formal: material number is the units aggregated together, from which number itself arises. Formal number is the formal unity resulting from the preexisting material unities, through which the formal number itself is constituted, as the formal unity of the binary is that through which the binary is formally constituted in the being of a binary. Moreover, there is one transcendental and another predicamental number. The transcendental, which is also called number in a qualified sense, is that which is attributed to many things that are not quantified by quantity of bulk; in this way the three divine Persons are said to be such, and one God, and Michael and Raphael two Angels. The predicamental is that which results from the division of a continuum, as Scotus deduces (*10. Met. in expositione T. 21. Et 4. Met. quaest. 2.*) from (*3. Phys. cap. 7. T. 68.*), and it coincides with the formal number described above. This, however, is adapted only to corporeal things that are capable of quantity.

Assertion: number is a real positive being. It is defended by the Doctor (*quest. 16. praedicam. 4. Met. quaest. 2. Et 5. eiusdem operis, quaest. 9. Et 1. distinct. 14.*), though he seems to treat it as problematic; nonetheless he promises elsewhere to determine and decide this difficulty, and he does so (*3. dist. 22. quaest. vn. antè §. Sed quidquid Logicè sub L. Et 1. Reportat. distinct. 24.*). The marginists on his Oxford writing (*passim alleg.*) also hold it. I brought this up on account of the twin Scotists who, in (*disf. 7. Log. quaest. 2. art. 1.*), holding the opposing opinion, say they do not firmly adhere to the assertion proposed, and though they would constantly defend it, nonetheless they are persuaded by the evidence of its arguments, as Canon also acknowledges (*4. Phys. quaest. 7. art. 2.*), and they declare that they freely and willingly embrace and defend it and publicly profess it. But it does not seem so firm and fortified by arguments that the contrary, which is common, as Scotus testifies (*in Reportat. cit.*) and Ockham (*1. distinct. 24.*

quaest. 2.), cannot be easily and conveniently defended, as will be clearly evident from the solution of the arguments of the opponents below. Now our assertion is established: the first species of any predicament is a real positive being, both because predicaments are series of real positive beings, and because real positive being is divided into ten predicaments (*5. Met. cap. 7. T. 14.*); but number is a true and genuine species of quantity, as has been proved (*passim memorato in initio huius artic.*); therefore number is a real positive being. Canon (*ubi supra*) distinguishes the major, saying that number is a real objective being in the intellect, but not an effective being and existing outside the intellect, such as a stone. On the contrary: apart from any act of the intellect, number exists from the side of things; therefore it is not only an object in the intellect, but truly exists outside the intellect as well. Hence Augustine adds: "Two and three are five, this is a necessary and eternal truth," and a proposition known from its terms, and therefore in no way dependent on the intellect. Others, such as Mastrius together with Bellutus, deny the minor, which is not really to be denied, both because Aristotle (*in praedicam. cap. de quantitate, & 5. Met. cap. de quanto*) and Scotus in the same place and in the places just surveyed clearly and explicitly admit it as true, and because the reasons offered below demonstrate it. Second: the object of a real science is real, both because sciences are divided as things are (*3. anima T. 38.*), and because a science takes its specification and determination from its object; but number is the object of a real science, namely Arithmetic, which is one of the mathematical disciplines, which no one doubts to be real and more evident than others; therefore number is a real being. The authors just cited respond that Arithmetic contemplates not only predicamental number but also transcendental number with its proportions and proportionalities, and yet transcendental number adds nothing beyond the numbered things, and so a being per accidens would suffice for the object of a science, as Poncius holds (*disp. 14. quaest. 4.*), nor would it be required to be one per se, of which the opposite is seen in all the individual objects of sciences. On the contrary: Arithmetic considers only that number which is caused by the division of a continuum, as I just cited from Aristotle and Scotus; but the number that arises from the partition of a continuum is only predicamental and quantitative; while the transcendental belongs to Metaphysics, whose concern is to contemplate all transcendental things; therefore the response is of no value, since predicamental number is one per se and obtains its own specific unity required for the object of a real science; and accordingly the object of Arithmetic is not a being per accidens, which does not fall under science, since it has no knowable properties demonstrable of it, as is evident (*6. Met. T. 6.*). I add: since Arithmetic is a subalternating science and principal, it contemplates number per se with its properties; but Music, which is a science subalternated to it, respects the number of sounds or number contracted through an accidental difference. Hence Suarez (*disp. 41. sect. 1. num. 16.*), perceiving the weakness of this solution, tries to adduce another, namely that number, besides the numbered material unities of numerable things, which are called material

unities, has absolutely no real specific formal unity except through the work of the intellect conceiving and fabricating this common unity of the said numbered things; and in this way number with such a unity elaborated by the intellect is established as the object of Arithmetic. But through this response Suarez falls into a greater inconvenience than the preceding one, since if the formal and adequate object of Arithmetic is and depends upon the work of the intellect, Arithmetic itself would not be a real science but a science of reason, since a science takes its entity and denomination from its object. But to make Arithmetic a science of reason is as absurd as to make Logic a real science. This inconvenience, however, Suarez and Mastrius do not wish to evade, lest they concede that number is one per se, which Aristotle clearly admits in the passage cited and (5. *Met. T. 19.*): "Six is not three twice, but once six," which means that the number six is one per se, constituted by its own unity in the being of six, and through this is distinguished from other numbers, as Scotus (3. *dist. 22. quest. vn. Sub L.*) says: "Nor is the quintet five units, but that whole that results from five units; otherwise if it were those units, it would be one just as a heap." And he premised (5. *Met. quaest. 9.*): "Number is one by its specific form, from which there is proper discreteness existing in five units as one matter, just as a human being by his specific form is one." And in the last Parisian work (1. *dist. 24. quaest. 1.*): "It is said in one way thus, that number has simply one unity, and there is one unity and formality from the last unity, according to the determinate distance." And Thomas (8. *Met. lect. 3.*): "For number is per se one insofar as the last unity gives species and unity to the number." Third: the object of sense is real, as is evident because it is sensible, and sense attains singulars, which are primarily and immediately existing real things; but number falls within the object of sense, since it is one of the five common sensibles (2. *anima T. 64.*). Canon responds (*citat.*) together with Mastrius that this is true with respect to the material being of number, not with respect to its formal being, which is through the intellect. On the contrary: number formally is from the side of things, since — without anyone thinking of them — there are four elements, three physical principles, and so on; and the intellect knows them as they are from the side of things; therefore number according to its material and formal being is a real being independently of the intellect. Finally: transcendental number is a real being pertaining to Metaphysics, which is a real science; therefore predicamental number is also a real being; for what is placed per se in a predicament, such as number, I clearly showed above to be a real being.

You will object first: Aristotle (3. *Phys. T. 68.*) writes that number is many units. And (8. *Met. c. 4. sum. vn. T. 10.*) he adds that number is not one but like a heap; therefore in the Peripatetic school number is not a real per se positive unity. I respond by expounding the passages of the Philosopher about material number, not about formal number. I add that the second testimony of the Philosopher is not rightly and faithfully cited by the adversaries; for in that passage it reads thus: "It is necessary for number to be something, by which it is one, which they

cannot now say; for by which it is one, since it is not one, but like a heap, or if it is, it should be said what it is that makes one from many, and the definition is one." This passage rather profits us than harms us. For there it makes a comparison between number and a definition, chiefly in that just as a number consists of many units, so a definition consists of many parts, yet is one; similarly a number is one, not with material unity but with formal unity, through which it is constituted in its formal and specific being, just as a human being through his form is one, as Scotus (*8. Met. in exp. T. 10. & 5. eiusdem, quaest. 9.*) says.

You will object second: for number to be a real per se unity, it must enjoy a certain unity, just as many things enjoy multiplicity, some enjoy sameness and identity, others diversity; but it participates in no unity from among the five enumerated by the Doctor (*1. distinct. 2. quest. 7. §. Sed hic restat. HH.*). For it does not obtain the unity of aggregation, which is the least, nor the unity of order, nor accidental unity, nor the unity of composition, nor of simplicity, as is evident to one who reflects and goes through each particular; therefore number is not a real per se unity. I concede the major and deny the minor. For number, since it is placed per se in the predicament of quantity and is its species, is composed of genus and differentia, as the Doctor hints (*proxime nominatus*); and accordingly it possesses the unity of composition.

You will object third: if there is a specific form of number, it is necessarily present in the numbered things, just as form is present in the matter it informs; but it cannot be made that the form of number is in all the numbered things, as the form of a ternary being in three stones of which one is in Rome, another in Paris, and a third in Turin; otherwise the form would inform many matters distant in place and situation, and an accident would be based in various and diverse distinct and distant subjects. The major is to be distinguished: inadequately, I concede; adequately, I deny, as is evident from a common real nature, which exists inadequately in one or two of its inferiors and adequately in all. See what I said (*in Log. lib. 2. quaest. 17. art. 5. & 6.*). Or if the major is conceded and the minor denied, it can be said that this is a privilege and characteristic proper to discrete quantity, just as it is peculiar to the genus of quantity to be predicated denominatively and concretely of its species, as I noted (*loco cit. l. 3. q. 5. art. 1.*). And it belongs to relation to arise upon the positing of termini, whether the termini are present or absent, as I asserted (*ibid. q. 6. art. 7.*); similarly it is natural for number to be in different subjects; and if all were identified, there would be no number, which always requires plurality and diversity of things, as the Parisians note (*c. de quantitate*) and Vigerius in his commentary (*1. dist. 24. quaest. vn.*).

You will object fourth: transcendental number adds no entity and unity beyond its material entities, as is evident from the ternary number of the divine Persons; therefore the same is to be asserted of predicamental number. The

consequence is denied; the reason for the disparity is that transcendental number is number in a qualified sense, and in the divine things all are one and the same; therefore in them there is not properly speaking number. For number properly and simply arises from the division of a continuum and is not found without the potentiality of material unities toward formal unity, as the Doctor touches on (*1. dist. 24. quaest. vn. non longè ab initio. A.*).

Article II. Whether Speech Is a True and Real Species of Discrete Quantity.

Scholastics who disagree about number in the preceding article likewise disagree in this one about speech. For those who remove number from the true species of quantity equally exclude speech from the list of true species of quantity, such as Joannes de Magistris (*cap. de quantitate*) and Suarez (*disp. 41. Met. Sect. 3.*). On the other side, those who place number among the true species of quantity also place speech in their series, such as Scotus (*quaest. 19. praedicam.*), Rivius (*cap. 6. de quantitate, quaest. 9.*), and the Complutenses (*ibid. disp. 13. quaest. vlt.*).

Note first that speech admits of many acceptations. First, it is taken for the elevation of the mind to God through pious and humble affection, as is seen in Augustine (*lib. de spiritu & anima.*). Second, for the significant vocal utterance by convention, discussed by Aristotle (*1. Perih. c. 4.*). Third, for an ornate discourse for the purpose of persuasion; in this sense Cicero (*a. de oratore*) calls speech "the queen of all things." Fourth, for an articulate vocal utterance consisting of more syllables and not more separate words, in terms of which a successive pronunciation takes place, as the word "man" and other expressions that are called speeches, suitable for composing song and harmony. And it is about speech so taken that the present discussion proceeds.

Note second that sound extends more broadly than speech so taken. For every speech is a sound, but not conversely. For a sound is a striking of air caused by the collision of two bodies; but speech is articulate, being formed by lips, teeth, tongue, and other instruments; and just as any striking of air is a sound, so any pronouncing of syllables is a voice; and accordingly there are as many voices as there are syllables that are ordered and successively uttered, from which speech is integrated, which is discontinuous and discrete, not indeed in subject or time, but in its intrinsic and essential form. Furthermore, in speech two things are most importantly distinguished: the sound, which is a quality, with its affections, namely whether it is acute or grave; and its discrete extension, which is also called expansion and prolongation; for if speech is delivered slowly and gradually, it is more extended than if it is quickly and promptly uttered; and the extension is more in one than in another, by reason of which one is short and another long, as is evident in Poets and Musicians. First assertion: speech is a true and genuine species of discrete quantity. The Doctor holds this in the passage cited, which he testifies is Aristotle's from (*cap. de quantitate*), who

furnishes it with two arguments: first, the intrinsic discrete measure is the species of discrete quantity, the proper nature and specific form of which is discreteness, as I noted above; but the parts of speech are measured by an intrinsic measure, which are its syllables, as is clear from the foundations just laid; therefore speech is to be numbered among the species of discrete quantity. Suarez (*citat.*) and Fonseca (*5. Met. cap. 13. quaest. 4. sect. 3.*) respond that the parts of speech indeed measure it intrinsically, but because they do not come together to constitute one per se quantum distinct from others, speech is therefore not counted among the true and real species of discrete quantity. On the contrary: just as from the material unities of number and its formal and specific unity there is made one per se, as I proved in the preceding article, so from the syllables of speech and its intrinsic and specific discreteness, which Scotus (*ubi supra*) writes to be unnamed, there is constituted one per se. Moreover, what is defined participates in one formal and specific nature, because a definition is a speech distinctly explaining the nature of a thing; but speech is defined as the discrete quantity of syllables; therefore it is one per se, and hence a genuine species of discrete quantity. Second: what is per se quantified by discrete quantity obtains an intrinsic and specific nature of quantity; but speech is per se quantified by discrete quantity, for it is short or long apart from the brevity or length of time; therefore it is not to be removed from the true species of discrete quantity. Fonseca responds (*passim memorato*) that all this depends on the convention and good pleasure of human beings, just as the signification of words does, and not on the intrinsic nature of speech. On the contrary: setting aside the signification of words and the will of human beings, speech still by its very nature remains short or long, compact or extended, on account of the discrete extension proper and intrinsic to it, as Scotus rightly infers (*praealleg.*); therefore the length or brevity of speech is not derived from time nor from another intrinsic thing. And so the length or brevity of speech is not sought from time or from another intrinsic thing.

You will object first: Aristotle, in (*5. Met. cap. de quanto*), recounting the species of quantity, makes no mention of speech; therefore according to Aristotle speech is not a species of quantity, whether discrete or continuous. Scotus adds (*1. distinct. 1. quaest. 2. §. Ad 1. O.*) that speech contextualized from many syllables does not make one per se, and therefore is not a true species of quantity. I respond that an argument drawn from negative authority does not conclude, especially because Aristotle had already in Logic, in the chapter on quantity, recounted speech in the list of species of quantity. Hence it was not necessary to again enumerate it, both because he had previously asserted and confirmed it by arguments — for which reason the common response that he spoke there in a famous and popular opinion is excluded, since what he states in another's opinion he does not usually fortify with arguments, as he does for speech. For this reason perhaps the Doctor writes there that he does not depart from that assertion, on account of the authority of Aristotle. To Scotus I say that he does

not there deal expressly with speech but by way of example, in which complete truth is not required, otherwise there would be not a likeness but an identity; but in Logic in the passage cited he treats of speech expressly and plainly and explicitly asserts it to be a species of discrete quantity.

You will object second: what is not per se quantified is not a true species of quantity, because a proper species of any thing is one per se; but speech is not per se quantified but by reason of syllables, in terms of which it is said to be long or short; therefore speech is not a genuine species of discrete quantity.

Confirmed: in speech there are found sound, motion, the order of syllables, and signification, which and similar things cannot constitute any species of quantity. I concede the major and deny the minor; to its proof I say that speech is quantified not only according to the syllables from which it is composed, but also according to its specific nature, which we said above to be discrete extension. To the confirmation I say that besides those enumerated, there is in speech the aforesaid discreteness, which Scotus says is its proper essential difference.

Question IV. On the Termini of Natural Things.

Article I. Whether Living Natural Things Have Certain Termini of Their Greatness or Smallness.

Paulus Venetus (*1. Phys. cap. 4.*) and other Philosophers of no small reputation, according to Toledo (*ibid. quaest. 8.*), think that living natural things are confined by no limit of their greatness or smallness. The common opinion, however, is that of Scotus (*quest. 24. praedicam. §. ad quaest. 5. Met. in expositione, cap. 15. T. 21. 2. dist. 2. quest. 9. §. Ad argumenta sub N.*), Ockham (*3. dist. 7.*), Gabriel (*ibid. distinct. 13. quaest. vn.*), Durant (*2. dist. 18. quaest. 1.*), Richard (*quol. 3. quest. 5.*), and the rest, who teach that naturally animate things are confined by certain and determinate limits of their greatness or smallness, which they cannot exceed.

Note first, from Scotus (*quaest. 19. Elench. Ad 1. quaest. Et 4. distinct. 44. quaest. 1. §. De secundo ante M.*), that the integrating parts of a natural animate whole are twofold: heterogeneous and homogeneous. The former are of different natures and hence are called dissimilar, such as bones, flesh, and the like; the latter are of the same nature and hence are called similar, as any part of flesh is flesh, just as any part of water is water.

Note second that the termini of natural things, some being intrinsic and affirmative and others extrinsic and negative, are comprehended under the quaternary number: two of greatness and two of smallness; the former is intrinsic, the latter extrinsic. The intrinsic terminus of greatness is that to which a living thing can attain such greatness but not greater — as if a human being reaches a quantity of six cubits but not seven or eight — and it is called the maximum of the kind, because among the quantities that a human being can

participate in, this is the greatest of all. The extrinsic terminus of greatness is that to which a living thing cannot attain such greatness but can have less — as if a human being cannot attain a quantity of seven cubits but can have less, namely six or five cubits — and it is called the minimum of the non-kind, because among the quantities that a human being cannot obtain, this is the least. The intrinsic terminus of smallness is that at which an animate being can exist under such a small quantity but not under a smaller — as if a human being can live under the quantity of one palm but not under the quantity of half a palm — and it is called the minimum of the kind, because among the smaller quantities that a human being can possess, this is the least. The extrinsic terminus of smallness is that at which an animate being cannot live under so small a quantity but can well exist under a larger — as if a human being cannot exist under the quantity of half a palm but can exist under the quantity of one palm — and it is called the maximum of the non-kind, because among the small quantities under which a human being cannot exist, this is the least.

Assertion: living natural things are constrained by intrinsic termini of their greatness or smallness. So Scotus (*ubi supra.*). It is proved first from Aristotle (*1. Phys. cap. 4. T. 36. Et 4. de gen. animalium, cap. 5. & 2. animae, cap. 4. T. 41.*): for all things constituted by nature there is a certain limit of growth and diminution. And (*7. polit. cap. 4.*): cities are surrounded by determinate limits, just like animals and plants. Second: every animate thing requires determinate organs and certain members for exercising its vital operations, and human beings use instruments of determinate greatness or smallness to produce artificial works; therefore there is a certain limit for animate beings with respect to greatness or smallness, which they cannot exceed. Third, from (*second animae T. 37.*): the soul is the first act of an organic body potentially having life; but its power, forces, and faculties are finite and limited (*1. Caeli T. 116.*). And experience confirms that each animate being, after reaching its proper and suitable greatness, no longer grows but gradually declines, as the natural heat fails and the radical moisture diminishes; for the natural heat acting on the radical moisture is weakened and reacting upon it is eventually consumed and ended, as we shall show abundantly in its proper place; therefore a certain limit and terminus is stabilized for animate beings with respect to greatness or smallness. And Augustine hands this down plainly and explicitly (*lib. de beata vita.*).

You will object first: it is narrated (*Gen. 6.*) that Giants flourished, who were of unusual greatness and extraordinary strength; therefore animate beings are not marked off by a certain limit of their greatness or smallness. I respond that although the Giants were tall, surpassing other men in stature, and robust in strength — according to the interpretation of Lyrar and according to some, monstrous — nonetheless they did not surpass the limit of man toward greatness. For they did not exist like a mountain, but perhaps reached the maximum of the kind, just as Pygmies reach the minimum of the kind.

You will object second: granted there is a certain limit of human greatness, a human being can still swell up and therefore grow, and can dry up and therefore shrink; therefore there is no certain terminus of greatness or smallness for living beings. Confirmed: let a human being reach the maximum of the kind; then by eating he will grow further, because through nutrition he will acquire new parts converted into his substance; therefore a certain terminus of his greatness or smallness is not to be established for him. I respond that given the hypothesis, such growth would not be intrinsic and per se but extrinsic and per accidens. To the confirmation: if he were in a stable age, it would be repaired to an equal amount with respect to the parts lost; but if he were in decrepit age, he would decline, as the parts gradually fall away and are lost, the natural heat failing.

You will object third: certain animals always grow, as is said of the crocodile. And certain plants are not confined by limits, such as the vine, the ivy, and the like; therefore living natural things are not to be assigned a certain terminus of their greatness or smallness. I deny the antecedent, whatever certain authors say, who are more fabulists than historians. The reason is that for producing a greater magnitude, a greater power is required, which cannot always increase in a living being, since life consists in moisture and heat; but these are weakened through continuous nutrition and the loss of heat and moisture; hence living beings grow old and thereafter perish.

Article II. Whether Non-Living Natural Things Have Termini with Respect to Greatness or Smallness.

This doubt can be treated in two ways: concerning what is actual and concerning what is possible. Concerning what is actual, all natural things are so ordered and disposed that they are enclosed and constrained by their termini and limits, in accordance with that saying (*Sap. 11.*): "The Lord has made all things in number, weight, and measure." Hence fire does not go beyond its sphere but is contained between the orb of the Moon and the supreme region of air. Likewise air is contained between fire, water, and earth, and so on for the rest. Concerning what is possible, however, there is controversy whether inanimate things can be confined by certain established and fixed intrinsic limits with respect to greatness or smallness. And certainly with respect to greatness there is the common opinion of Scotus (*2. distinct. 2. quest. 9. §. Ad argumenta sub N.*), Ockham (*3. quaest. 7.*), and the adherents of both — except for Landus (*1. Phys. quest. 16.*) and a few others, to whom the Complutenses now join themselves (*disp. 27. quest. 2. §. 3.*) — who deny that inanimate natural things are limited and confined by any termini toward greatness. But with respect to smallness there is more vigorous dispute. For although Scotus and Ockham teach the same, nonetheless the Thomists cited by the Complutenses (*question 3.*) and many others outside their school hold that with respect to smallness inanimate things are finite and limited, so that they reach a last terminus which they cannot go beyond toward smallness.

First assertion: inanimate things with respect to greatness are unlimited and unbounded. So the Doctor (*ubi supra.*). It is established first from Aristotle (2. *animae* T. 41.) in explicit words affirming that fire grows to infinity if combustible things are always applied to it. And it is written (*Prov. 30.*): "Fire never says it is enough," because, as Lyran adds there, from the application of combustible things its power to burn more always increases. Second: such non-living things always grow and are strengthened through things intrinsically applied to them, as with rain and precipitation falling and entering a river, if it continually grows, the river itself grows; since inanimate things grow not by internal reception as animate things do, but by external juxtaposition, and accordingly their growth has no end and no terminus. Third: if fire were to reach the maximum of the kind, and tinder were applied to it, either it would burn the tinder or it would not; not the second, otherwise an agent properly disposed and approximated to a patient rightly disposed would naturally not act, which is plainly false; if the first, therefore it would grow and be constrained by no limit. Add that from what will be said in the following question, there is a syncategorematic infinite, and God can produce finite effects to infinity, which surely indicates that inanimate things too can grow to infinity. The Complutenses respond (*cit. §. 4.*) in two ways, and say first that given the hypothesis, fire indeed would burn the tinder, but would not unite to itself the newly generated fire, and it would only be contiguous to it, making one by aggregation. On the contrary: things of the same nature, if they come together, are simultaneously united, as is evident from river water joined to sea water and other homogeneous things; but newly produced fire is of the same nature as the preexisting fire, nor can one be distinguished from the other, since one entire one appears. Moreover, a small fire can be united to another fire; therefore also a large fire can undergo the same union. For if a lesser power can produce it, all the more a greater power can cause such an effect; therefore if a small fire is united to another fire, surely a larger fire, such as the one presupposed, can undergo the same union with another fire, whether produced by itself or by another. And this is clear from experience and sense, while the opposite appears with respect to living things and cannot be rightly denied by the adversaries. They respond second: given the case, fire would be in a state of corruption and on the way to destruction. On the contrary: what has reached its peak is not in a state of corruption but of perfection, as is evident from fire existing in its sphere, from a man possessing glory, and from Christ having the highest grace; but if an inanimate thing were to reach the maximum of the kind, it would be in the highest state that it could participate in, as is clear from the Giants (*Gen. 6.*), who perhaps elevated to the maximum of the kind were most robust and most celebrated, so that they rose against God and strove to pile Pelion upon Ossa. If, therefore, the inanimate thing reaches the aforesaid limit, it enjoys a state not of corruption but of perfection; furthermore, such an inanimate thing in such a limit and state is stronger and more active, as is clear from a large fire and a burning furnace; and possessing great power it frees itself from contraries and defends itself from all

corruption more than if it possessed small power, as is clear from a large and a small fire — the latter is attacked by contraries and is defeated; but the former resists and persists victorious. Moreover, the cause of corruption in living things is that they are nourished by internal reception, by reason of which, acting, being acted upon, reacting, and being acted upon again, they eventually perish and are consumed; but non-living things grow by juxtaposition; therefore if more things are placed next to inanimate things, they are further increased and strengthened, and accordingly are freed from all corruption.

Second assertion: inanimate things with respect to smallness acknowledge no limit or boundary. This is handed down by the Doctor (*2. distinctione secunda, quaestione nona, Met.*) and is derived from Aristotle (*l. de sensu & sensili, capite tertio.*). It is established first: inanimate things are continuous, which, as has been said (*quaestione secunda huius libri, articulo quarto*), are divisible into always-divisible things; therefore no terminus with respect to smallness can be assigned to them. The consequence holds: if a minimum were given, since it would be a quantum, it would surely be divisible into other parts and halves, and so on; and accordingly it would not be a minimum, because it would still be distributed into smaller and smaller parts. The adversaries would respond that the argument concludes concerning mathematical quanta, not natural ones, since a natural thing, to retain its form, requires a certain and determined quantity, without which it cannot exist and be conserved nor perform any operations, as Aristotle seems to concede (*nunc alleg. c. 6.*) and Scotus (*ubi supra.*). Second: with respect to greatness, non-living things are not confined by a terminus, as nearly all admit; therefore neither with respect to smallness. The consequence is evident because the same reason applies to both, since they are homogeneous and capable of growth and diminution. The proponents of the contrary position would deny the parity because toward greatness there is a quantity under which a form can exist, but not toward smallness, as I noted a little before, and the Scotus cited exemplifies of a natural thing that if so small it no longer falls under sense.

You will object first: Aristotle (*1. Phys. T. 38.*) writes that there is a minimum flesh, from which no other can be extracted. And (*2. anima T. 41.*): for all things constituted by nature there is a certain terminus of greatness and smallness. I respond that Aristotle there speaks of the parts of a living being, such as flesh. In the preceding article, however, it was established that living beings participate in a terminus of their smallness and greatness. The same he also asserts in the latter place, saying that this applies to animate things, not to inanimate things like fire, which lacks a soul.

You will object second: the same Philosopher (*2. caeli, T. 17. & 1. Eth. cap. 7.*) puts in writing that each natural thing is for the sake of its operation; but unless a certain terminus of smallness is established for a natural entity, it would be reduced to such smallness that it could no longer produce any action; therefore

inanimate things are not to be denied a certain terminus of their smallness. The major being conceded, to the minor I say: if such a natural thing could no longer operate, this would not come from an intrinsic source but from an extrinsic one, as we experience with a small fire, which cannot long exist because it is attacked and weakened by air and is eventually consumed.

You will object third: if an inanimate natural thing is unlimited and unbounded with respect to being and acting, then similarly with respect to perfection, because the latter follows upon the former; hence, since God is infinite in entity and therefore in perfection, if an inanimate thing has no limit of its smallness, then neither does it have a terminus of its perfection. I respond that the argument concludes concerning perfection in a qualified sense and accidental perfection, not concerning perfection simply speaking and essential, of which kind is the perfection of God.

Book VII. On Time.

Question I. On the Nature of Time.

Article I. Whether Time Exists.

That it is an arduous and difficult matter to investigate the nature of time is indicated by Augustine in *11 Conf., cap. 15*, where, addressing God, he says: "Lord, I still do not know what time is." By time, however, we understand a certain successive duration by which natural things endure. Time can moreover be divided into actual and potential, as Scotus indicates in *Quol. 11, art. 2*; then into past, present, and future; and again into year, month, day, and hour.

Assertion: Time exists. So holds Scotus, as just mentioned, in §. *De secundo F.*, and in *2 dist. 2, quaest. 2, sub D. & 9. P.*, and elsewhere, and in *4 dist. 48, quaest. 2*. This is proved first from Scripture: *Genesis I*, "Let there be luminaries in the firmament of heaven, and let them divide the day and the night, and let them be for signs and for seasons and for days and for years." *Acts I*: "It is not for you to know the times or the moments." *Ecclesiastes III*: "All things have their season, and all things under heaven pass away in their appointed times." *Apocalypse X*: "Time shall be no more." Second, from the Fathers, expressly: *Dionysius in the book On the Divine Names, cap. 13*, and *Augustine in 11 Conf., cap. 14*: "Nothing is more familiar than time." Third: some things are permanent, others successive, and the latter endure through time. Hence time is on everyone's lips, and nothing seems more familiar to us; therefore there is no need to spend further time persuading and demonstrating the existence of time, since it is plain and clear to all.

You will object: every whole coheres from its parts, as a man from soul and body; but if time existed, it would be some whole whose parts do not exist — as

after Aristotle in *4 Phys., cap. 10*, Augustine writes in *lib. 83 quaest., quaest. 17*, saying: "the past is no longer, the future is not yet, nor the present, because it flows away" — therefore time does not exist, since its parts do not exist. I grant the major and deny the minor. For although time does not have parts that are actually permanent and simultaneously coexisting, it nonetheless participates in parts that continuously flow and stream, since it is a successive continuum, as Aristotle cited and Augustine in the place noted above indicate, and *Psalm 38, 131*, and Scotus intimates in *5 Met., quaest. 8*, and *2 dist. 2, quaest. 9, §. Ad argumenta B.*, and this is confirmed by Vives in *8 De Civitate, cap.*, with the authors cited by him.

Article II. Whether Time Is a Real Being.

Aureolus in *2 dist. 2, quaest. 2, art. 2*, Pererius in *lib. 12, cap. 13*, following Averroes in *4 Phys., com. 189*, and Galen as cited by *St. Thomas in the opusculum On Time, cap. 1*, Janduno in the present *quaest. 27*, and Antonius Andreas in *5 Met., quaest. 9*, maintain that time is the work of the soul and the fabrication of the mind. The Doctor Angelicus in *4 Phys., lect. 13*, and others of the same school support them, suspecting that time derives its completion from the intellect. The more common and truer opinion, however, drawn from the Subtle Doctor in *2 dist. 2, quaest. 1 & 9*, and in *4 dist. 48, quaest. 2*, and from Mayr, *2 d. 14, q. 10*, Canon, *4 Phys. s. art. 2*, Tatar, Joan. de Magistris, Parisiensis, Tolet, Ruvio, and others — teaches that time is a real being, apart from any operation of the intellect.

Note first that time admits of many senses. First, it is taken for the disposition and temperament of the air, in which sense we are accustomed to say that the weather is clear or cloudy, calm or overcast, healthful or unhealthful. Second, for the pleasantness and happiness of the life that some enjoy in prosperity, in which sense *Job XXI* reads: "They spend their days in good things, and in a moment they go down to hell." Third, for the opportuneness of things to be done, as *Ecclesiastes III*: "A time to plant and a time to uproot what has been planted." Fourth, for the successive duration of things — and it is time taken in this sense that we now discuss.

Note second, from Canon cited and Tatar in *4 Phys., quaest. ult., scibili I*, that time can be examined in two ways. In one way, with respect to its entity and successive continuity: in this sense it exists on the part of the thing independently of the soul and its intellect, since it existed before the soul's creation, as is plain from *Genesis I*, where mention of time is made before man was formed, who was the last of all things to be created. In another way, with respect to its discretion and partition into years, months, days, and hours: for in this way these are distinguished and divided by man as if they were separated from one another on the part of the thing, even though they are in fact conjoined and connected without any real division and partition of parts, with the perennial flux and continuous succession that belongs to the nature of time, which is essentially continuous and successive. In this sense are to be

understood *Aristotle in 4 Phys., cap. 14, T. 131, Augustine in 11 Conf., cap. 28, Scotus in 5 Met., quaest. 9*, and others, when they affirm that time formally taken is the work of the soul and a being of reason, inasmuch as since the parts of time are undivided and inseparable from one another, while the intellect divides them and separates them from one another, this undoubtedly depends on the soul and is rightly reckoned its effect.

Assertion: Time is not a being of reason, nor does it derive its completion from the soul, but is a real being existing on the part of the thing, independently of any act of cognition. So holds Scotus in the citations at the beginning of this article. This is proved first from the testimonies of Scripture adduced in the preceding article, with reference to which the Church sings at Matins in the hymn of the first Sunday of Lent: "King and maker of the times." Second, from the Fathers: Augustine in *lib. 4, 99 Super Numeros, quaest. 23*, calling God the creator and ordainer of times; and in his commentary on *Psalms 43*: "I see the times changed; the creator of times is not changed"; and in *lib. contra sermonem Arrianorum, c. 1*: "Time is certainly a creature of God"; and Damascene in *1 fidei, c. 11*, and in *2 of the same work, 6. 1 in fine*: "God is the maker of all ages." Third, from Aristotle, who in *lib. praedicam., c. de quantitate*, and in *5 Met., c. de quanto*, enumerates time among the species of quantity; quantity, however, has real species, since it is a real genus and the first among the genera of accidents, which are real; therefore time is a real being. Fourth: what has real properties is real, for a property proceeds from the nature of which it is a property — so if that nature is real, the property that follows upon it is likewise real. Now time possesses real properties, such as length or brevity, which are undoubtedly real beings. Moreover, motion is a real being, as is held as established by all; therefore so is time. The consequence holds because time is the measure of motion, as will be clear in the next article. Again, independently of any act of cognition, sublunary things endure successively; but successive duration is time. The Sorbonne as a whole reproves the opposing opinion as erroneous.

Objection I: Aristotle in *4 Phys., c. ult.* writes that time so depends on the soul that, if the soul were to cease, time would likewise cease to be; therefore in the school of Aristotle, time is a being of reason. Augustine in *1 De Civitate, c. 26*, and *11 Conf., cap. 28*, seems to hold the same view. Reply: The Philosopher speaks there in a conditional and questioning manner, and subsequently asserts positively that time is not fixed and permanent but fleeting and successive. Or I say that he considers time not according to its continuous and successive entity, but according to the assignment and division of its discrete parts, which I noted in the second note as being effected by the intellect. Augustine cited must be interpreted in the same way, as he himself indicates in his commentary on *Psalms 100*, and in *tract. 31 in Ioan.*: "Every day in this present time comes only in order not to be; every hour, every month, every year — none of these stands still; before it comes, it will be; when it has come, it will not be; when it has not yet come, it is not."

Objection II: What is composed of parts of reason is a being of reason, for such as the whole is, such are its parts; but time is composed of parts of reason. Therefore it is a being of reason. The major is clear. The minor is urged: time consists of the past, which does not exist; the future, which likewise does not exist; and the present, which does not exist except in an instant. This is confirmed by Augustine in *11 Conf.*, c. 15, who says that of the whole of time we have only one now or instant. I grant the major and deny the minor. To its proof I say that time indeed does not have permanent parts actually coexisting simultaneously, but rather parts that are fleeting and continuously flowing, since it is a successive being. Augustine expressed this in his commentary on *Psalms* 76: "While I speak syllables, if I say two syllables, the second does not sound until the first has passed; and the very syllable, if it has two letters, the second letter does not sound unless the first has gone." Hence Aristotle and Augustine indicate the fluidity of time, and do not hold that it consists in a moment and in the present, indivisible now. You will press: *Psalms* 76: "I thought of the days of old, and had in mind the eternal years." If, then, the days are eternal, since eternity is all simultaneous, they are not fleeting, nor therefore is time. I reply with Augustine that those days, of which the royal Psalmist makes mention, are the days of God, of whom it is written: "But you are always the same, and your years will not fail." Hence the same holy Doctor adds in his commentary on *Psalms* 101: "All this time from Adam to the end of the age is a tiny drop compared to eternity." He therefore speaks not absolutely but comparatively.

Objection III: Time is described as the number of motion according to before and after, as will be clear in the next article; but number depends on the soul, for it is the soul that counts, assigns, and divides the parts of time; therefore time is the work of the soul and hence a being of reason. I reply by way of explanation and distinction of the major: time is a numbering number — I deny; or rather a numbered number, or better, a measure, in Scotus's interpretation — I grant. And that this may shine forth more clearly, let the following be said.

Article III. What Time Is.

Philosophers toil greatly and in diverse ways to track down and investigate the nature and essence of time. The ancients were divided into three camps, as Aristotle attests in *4 Phys.*, c. 10. Some, among whom Plato is numbered in the *Timaeus*, hold that time means nothing other than the circulation or circular revolution of the celestial world. Others, whom Gregory follows in *2 d.* 2, q. 1, art. 1, judge that time is the heaven. Still others, such as the Nominalists, to whom Fuentes in *4 Phys.*, q. 3, diff. 3, art. 2, 3, and Suarez in *disp.* 50, *Met.*, sect. 9, adhere, think that time coincides with motion. Aristotle, however, in the passage just mentioned at *T.* 101, and all his interpreters, assert that time is the number of motion according to before and after.

Note that the succession of time proceeds from the succession of motion, and the succession of motion proceeds from the magnitude of the mobile body and

of the space to be traversed. For from the fact that the body has such a magnitude and mass, and that such an interval is to be crossed, it follows that the motion is so continuous and successive, and its measure is time — for the delay brought about in the motion of a body is measured by time. Therefore time is rightly called the measure of motion according to before and after.

Assertion I: Time is neither circulation, nor heaven, nor motion. The assertion has three parts. The first part, which is that of Aristotle, recently cited at *T. 93*, and is accepted by the Doctor in *9, 15 Praedicam., not far from the beginning, vers. Item qualibet pars*, is urged as follows: no part of a circulation is a circulation, as is self-evident; but every part of time is time — as past, present, and future are times — therefore time is not circulation. The second part, which is presupposed by the Doctor in *2 d. 2, q. 1*, is not attacked by Aristotle with a reasoned argument but is indicated by him to be absurd and foolish. It can be disproved as follows: heaven is a substance, while time is an accident; and moreover heaven can exist without time, as after the day of judgment time will cease while heaven will persist, since it is incorruptible; therefore time is not heaven. The third part is deduced from Scotus in the citations above and in *4 d. 48, q. 2*, and is supported by Augustine in *11 Conf., c. 24*, and is proved thus: first, the property of a thing is not the thing of which it is a property, just as risibility is not man; but time is an attribute of motion, since it is its measure; therefore time is not motion. Second: things whose attributes are not identical do not coincide, as is established by induction; but the attributes of motion are not the same as those of time — for motion is fast or slow, while time is short or long, great or small — therefore time is not motion.

Assertion II: Time is aptly defined as the number of motion according to before and after. This is Aristotle cited at *T. 101*, and is indicated by the Doctor in the passages cited above and in *5 Met., q. 8*. It is explained before being proved. "Number" means a continuous successive measure. "Motion" is placed as its subject, from which time flows as its attribute. "According to before and after" means according to the prior and posterior parts of motion, as has been explained in the preceding note. The conclusion thus explained is urged as follows: first, from Aristotle in the passage just cited, who offers and defends this definition of time and vindicates its expositors against the attacks and darts of adversaries; second, the definition just given possesses in its own way genus and difference, and is therefore legitimate — for "number" or "measure" is substituted in the place of genus, while the remaining terms serve as differentia. Moreover, to each being its proper measure must be assigned: to God, eternity; to the created incorruptible and permanent being, the aeon; therefore to the corruptible and successive being is to be attributed time, which is a fleeting and successive measure.

Objection I: Number is a species of discrete quantity, as is plain from *lib. praedicam., c. de quantitate*; but time is a species of continuous successive

quantity, from the same passage. Therefore "number" is improperly placed in the definition of time. Reply: with Scotus, instead of "number," "measure" should be placed, through which the nature of time is clearly perceived, namely, the measure of motion. Or it can be said that time is called a number because it has parts that are discrete not in continuous quantity — for in themselves and essentially they are continuous and successive — but in quality, that is, by the convenience and utility of men they are discrete and divided, through the operation of the intellect.

Objection II: The measure ought to be better known than what is measured, since through it we arrive at knowledge of what is measured, as the Doctor explains well in *10 Met., in the exposition of the text toward the end of c. 2*. But motion is better known than time; therefore time is badly described as the measure of motion. I distinguish the major: in the character of a measure, I grant; in the character of such a being, I deny. For it is not necessary to know the nature of such a measure in order that something be measured through it; it suffices that the measure lead to knowledge of what is measured, even if its essence remains unknown. This can be illustrated by the intelligible species, which leads us to knowledge of the object of which it is the representative, even though the nature of that species is itself unknown.

Objection III: *Genesis I* narrates that God made the sun and the moon to be for signs and seasons; and *Psalms 103*: "He made the moon for seasons" — but the moon and sun are below the primum mobile. Therefore time cannot be the measure of the primum mobile, but rather of the sun and moon. Reply: with Augustine in *2 de Genesi ad litteram, c. 14*, and *12 De Civitate, c. 14*, time in those passages is taken for the opportuneness of things to be done, and thus it is subjoined there that they should govern the day and the night — that is, that men might conduct their affairs seasonably, in sowing, harvesting, sailing, and the like. We, however, take time as the measure of the motion of the primum mobile, which is called common or universal time.

Objection IV: Time is the measure not only of motion but also of rest. For in *Joshua X*, while the sun stood still, that rest could be measured; therefore the definition of time is deficient, lacking the case of rest. Aristotle replies at *cit. T. 118*, with the agreement of Scotus in *2 d. 2, q. 4, §. Concedo, sub C.*, that motion is measured by time per se, and rest only per accidens. I add that opposites have the same treatment, as stated in *2 Top., c. 14*; but motion and rest are opposites, like a habit and its privation; therefore they are measured by the same measure of time, as Scotus explains well in the passage just cited before D.

Article IV. Whether Time Is Distinguished from Motion.

Although from the preceding article it is clear what must be said in the present one, nevertheless, for fuller instruction and for settling the various and diverse contentions of the Philosophers, I am pleased to examine carefully how time is

distinguished from motion. Some — whose names Aristotle passes over in *4 Phys.* — identify time with motion. Fuentes and Suarez, named in the preceding article, agree with them. Others, such as Janduno in this book at *q. 18*, Burley in his exposition of *T. 102*, and John of Maistre, distinguish time from motion really. Scotus, however, in *11 Met.*, in the commentary on *c. 2*, *summa 4 in fine*, writes in clear terms that time is really the same as motion, differing from it only formally. He intimates the same in *4 d. 48, q. 2*, to whom agree Mayr in *2 d. 14, q. 11*, Antonius Andreas in *5 Met.*, *q. 11*, Canon in *4 Phys.*, *q. 7, art. 3, dub. 3*, Orbellio in the same place, Faber in *Theor. 49*, and Poncius in *disp. 46, quaest. 2, concl. 1*.

Note first, from Scotus in the commentary on *11 Met.* in the passage just cited, that the present controversy is not about whether the time that is the measure of the motion of the primum mobile is distinct from the motion of the inferior orbs — for it is certain that these differ, both because they have really distinct subjects, and also because they can be separated from one another, as if God were to destroy the primum mobile while preserving the remaining heavens, then the lower heavens would exist without the uppermost, and these would be moved and endure without it. But the question is whether the time that is the duration of the first heaven differs from the motion of that same first heaven — and concerning this the opinions stated above obtain.

Note second that motion is divided into common and particular. The common or general motion is the motion of the primum mobile, by which the remaining motions of the inferior orbs are moved, drawn, and regulated. The measure of the motion of the primum mobile is common time, for by this measure the motions of the other spheres are measured. Particular motion is what belongs to any other body distinct from the primum mobile, and the measure of each of these is called particular time, which others call extrinsic time. For this reason Christ the Lord says in *John VII*: "My time has not yet come, but your time is always at hand." In this way particular times are distinguished according to the particular motions of any thing; and thus in *Genesis VI* the time of man's life is assigned: "His days shall be a hundred and twenty years." And in *John XIV* the Savior, addressing Philip, says: "So long a time have I been with you, and you have not known me."

Assertion: Time differs from motion not really but formally. The Doctor in the passages cited above and in *5 Met.*, *q. 10, §. Et concedo* supports this. The first part is proved thus: first, an attribute is not really distinguished from that of which it is an attribute, as Scotus shows in *2 d. 16, q. vn.*; but time is an attribute of motion, as stated in *4 Phys.*, *Summa 3, q. 9, T. 130*, and also in *8 of the same work, T. 10*, with the agreement of Augustine in *11 Conf.*, *c. 24*; therefore time is not really distinct from motion. Second: things that really differ and are absolute can at least by divine power be separated from one another, as Scotus proves in *2 d. 1, q. 4, §. contra statim*; but time cannot exist without motion, since it derives its being from motion, as I noted in the note of the preceding article, and as

Aristotle clearly teaches at *cit. T. 105*. Moreover, motion enters into the definition of time, for time is the number of motion according to before and after; therefore time is not really separated from motion. Hence Augustine in *5 de Genesi ad litteram, c. 5*, subjoins: "If there were no motion, whether of a spiritual or corporeal creature, there would be no time at all." And in *lib. contra sermonem Arrianorum, c. 1*: "Time cannot exist without certain motions of creatures." The second part is urged: first, from Aristotle, both in *1 Praedicam., c. quantitate* and in *5 Met., T. 18*, who enumerates time as a species of quantity distinct from motion; therefore, since they do not differ really as proved in the first part, they are inferred to differ from one another formally. Second: things that possess distinct definitions independently of the intellect, and that are inseparable from one another, are formally distinguished, as I showed from Scotus in *Log. 1, 2, q. 1, art. ult.* But time and motion possess distinct definitions: time is the number of motion according to before and after, while motion is the act of a being in potency as it is in potency. Again, time is a measure, while motion is measured by time; but measure and what is measured, subject and what is in the subject, differ at least formally from each other. Finally, motion is fast or slow, while time is short or long; and the swiftest mobile traverses in a short time a great space, which a slow mobile will not accomplish in a long time; therefore between the two there is a formal distinction.

Objection I: Scotus in *2 d. 2, q. 1, §. Ad secundam partem H.* establishes that duration and measure are not distinguished from the thing of whose duration and measure they are; and in *4 d. 48, q. 2, §. Ad q. H.*, and in the *Reportatio* on the same distinction and question, *Ad 1.*, he subjoins that time adds to motion nothing other than the relation of measure. Therefore either they do not differ from one another, or if they are distinguished, they are really distinguished — since measure and what is measured are relatives, and among relatives whose extremes are real there is a real distinction, because one has reference to the other. Reply: in that place Scotus discusses the matter probatively and speaks of the existence of the Angel and of its duration, which is the aeon; but we are speaking of time, which is the duration of a successive thing, and that the same account and parity do not hold in that case is indicated by the same Doctor in the same place, *§. contra istud sub E.*, after *Augustine 11 Conf., c. 23*. To the other testimonies I say that time adds to motion, of which it is the measure, an intrinsic — not extrinsic — character of measure, pertaining to the first and not to the third mode of relatives, as the Doctor explains in the same passage.

Objection II: Time can exist without motion; therefore time is really distinct from motion. The antecedent is shown from *Joshua X*: while the heaven stood still, a battle was fought which, according to Augustine in *11 Conf., c. 23*, lasted three hours, or according to others cited by Lyran at the end of that chapter, a full artificial day — so that the day was doubled, that is, twenty-four hours. Thus there was time without motion. I distinguish the antecedent: universal time can exist without the motion of the primum mobile — I deny; particular time, such

as was the duration of the aforementioned battle — I grant. Or it can be said that that battle lasted not by positive time but by privative time, just as a privation is measured by the measure by which its corresponding habit is measured, as I made plain above regarding rest and motion. You will say: if time is continuous and uninterrupted, how is it said in the cited passage that the sun stood still, and in *4 Kings XX* and *Isaiah XXXVIII* that it went back ten degrees? I say this is to be understood with respect to the natural order, not supernaturally, as it is narrated to have been done at that time; and especially since a small thing is accounted as nothing; and therefore there is nothing to prevent time from being called continuous and uninterrupted.

Objection III: There is one and the same time everywhere and among all, as stated in *4 Phys., T. 95, 133, 134*, through which sublunary things endure; but motions are many, in proportion to the plurality of mobile bodies; therefore between time and motion there is a real distinction. I distinguish the major: there is one common and universal time — I grant; particular and singular time — I deny. For just as each thing has its own proper essence and existence, so it possesses its own proper and intrinsic time, as I explained in the second note.

Objection IV: Time is the offspring of motion, and has a distinct being from motion, just as Augustine says in *q. 81, novi testamenti*: "Gold is born from the earth but is not earth; food is born from wood but is not wood; and a foal is born from a donkey but is not a donkey." But an offspring or effect is really distinct from its cause; therefore time is really distinct from motion. Reply: time is called the offspring of motion not as something produced by a real change, but by a simple emanation, just as an attribute proceeds from its subject of which it is the attribute; and therefore motion and time are distinguished only formally.

Article V. Whether There Is a Discrete Time Distinct from Continuous Time.

The Doctor Angelicus in *1 p., q. 10, art. 5*, Henry in *Quol. 12, q. 8*, Cajetan, and the other Thomists try to introduce into their school a discrete time distinct from continuous time, through which they think the operations of the Angels are to be measured; against whom rise up the Subtle Doctor in *2 d. 2, q. 2, §. contra & 2 Rep. ibid., q. 1*, Lychetus, Gratianus Brixiensis, Rada in *contr. 4*, and others, who deny this kind of discrete time as distinct from our continuous time.

Note first that the Thomists consider the operations of the Angels in two ways: first, all of them taken together and collected, even though one precedes another and one succeeds another — and in this way those schoolmen judge that such operations are measured by discrete time, which is nothing other than the duration of the operations of the Angels taken together. In the other way those authors contemplate angelic operations taken separately, one after another, and in this way they judge them to be measured by an instant of discrete time.

Note second that the principal measures of things are commonly reckoned to be four: eternity, the aeon, time, and the instant, which Augustine touches upon in *1, 83 quaest., q. 19*. Eternity is described by Boethius in *1 De Consolatione, prosa 6, metro 10*: "the whole, simultaneous, and perfect possession of unlimited life" — that is, eternity is a duration without beginning or end, by which God alone endures, since He alone is eternal, having no beginning or end. Hence Augustine subjoins in his commentary on *Psalms 2*: "In eternity nothing is past, as if it had ceased to be, nothing is future, as if it were not yet; but there is only the present, because whatever is eternal always is." And in his commentary on *Psalms 146, in fine*: "Eternity consists in four syllables; without beginning and without end it is." And in his commentary on *Psalms 100*, addressing God: "Your years are eternal, your years which do not change, shall be in generation after generation." The aeon is defined as the duration of a permanent being that is indefectible in act but defectible in potency. This is mentioned by Aristotle in *1 Caeli, T. 100*, and by Augustine in *1, 83 quaest., q. 72*, where he calls the aeon stable. This measure belongs to Angels, rational souls, and the remaining beings that persist in their being. Time is the duration of a successive and continuously fleeting thing. This is called mutable by Augustine in the passage just cited. The instant is the momentary duration of an instantaneous thing, such as generation, illumination, and resurrection — as in *1 Cor. XV*: "In a moment, in the twinkling of an eye." To these some add the instant of nature and the instant of origin, but in reality these are not durations but rather presuppositions and prerequisites, for what is prior in nature and origin is presupposed and required prior to what is posterior in nature and origin. The instant of nature belongs to things that are simultaneous in time, yet one is presupposed before the other — for example, animal is prior by nature to man, and the more universal are prior by nature to the less universal. The instant of origin is applied to those things of which one originates from the other, even though both are simultaneous in nature; in this way theologians say that in the divine, the Father is prior to the Son in origin — so that in the first instant of origin is the Father, in the second instant of origin is the Son, and in the third is the Holy Spirit.

Assertion: Discrete time distinct from continuous time is not to be admitted. So holds the Doctor in the passages cited above. This is proved first from Aristotle in *4 Phys., Summa 3, c. 6*, who, treating extensively and carefully of time until the end of that book, nowhere mentions discrete time, nor does he say anything about it in any of his works; therefore discrete time is to be rejected from the Peripatetic school. You will say: Aristotle thinks that the Angels, whom he calls Intelligences, are certain gods; therefore it is not surprising if the Philosopher did not wish the operations of those beings to be measured by discrete time, but definitively by the measure by which gods are measured, and for this reason introduced no other time besides continuous time into Peripateticism. Against this: Aristotle did not fall into polytheism; indeed, it may be that precisely because he did not worship multiple gods, lest he suffer capital

punishment like Socrates, he left Athens and went to Chalcis, where near death he sought pardon of God for his sins, as Fonseca attests in the proem to the *Metaphysics, toward the end of c. 1*, from others cited by him. The Philosopher accordingly acknowledged one true and sole God, whom he openly confesses to be the ruler, governor, and director of the universe, in *12 Met., at the end*; and the same Philosopher admits in the same place at *T. 47, sum. 2, c. 4* several Intelligences corresponding to the plurality of the moveable Heavens, caused by God — whom he calls the first cause, the first mover, and the first being — as Scotus shows in *1 d. 8, q. 5*, and in *Quol. 7, §. sed quia*. I add: in *1 Caeli, T. 100*, he enumerates the aeon, by which those Intelligences endure; therefore in his school there exists no discrete time. Second: beings ought not to be multiplied without necessity, but there seems to be no necessity for multiplying a discrete time distinct from continuous time; therefore discrete time is one and null. The major is Aristotle's in *1 Phys., T. 52* and is denied by no one. The minor is proved: if any reason compelled the concession of such a time, it would be especially the reason of St. Thomas, who holds that the operations of Angels do not depend on the Heaven, and for this reason are to be measured not by continuous but by discrete time. But this reason is of no weight, because the operations of Christ the Lord after His resurrection did not depend on the Heaven, and yet they were measured by continuous time. Likewise the actions of the Blessed, and after the day of judgment the operations of all men, will not be measured by discrete time, as the Thomists themselves do not deny; therefore neither are they measured by discrete time now, since they are of the same nature and species, and accordingly no other measure beyond those already described is to be devised to measure them.

You will say that those operations of the Blessed — such as vision and fruition — are measured by participated eternity. For since they are of the divine and supernatural order, a measure that is in some way divine is owed to them, which is rightly called participated eternity, since they will always be and will endure perpetually, like God. Against this: in *2 Cor. XII* it is read that St. Paul had such operations when he was caught up into Paradise and heard arcane words which it is not lawful for a man to speak. For he was then blessed with that beatitude which the scholastics call hourly and temporary; but such a happiness was not measured by participated eternity, because it did not last long but passed fleetingly; therefore neither is the beatitude of the other Blessed, which is perpetual, measured by participated eternity, since both are of the same species and order. Third: every being is either permanent, persisting in its being, or successive, continuously flowing away; the permanent is measured by the aeon and the successive by time; but certain of the operations of the Angels are permanent, such as the vision and fruition of God, while others are successive, such as their mutual locutions and their local motions; therefore the former are measured by the aeon and the latter by time; and therefore no discrete time is to be devised to measure all of them.

You will say that the operations of the Angels are permanent, one succeeding another, and having an end; therefore they are not measured by the aeon, which is the measure of permanent beings without end, but by discrete time, which is the measure of permanent beings that have an end and a terminus. Against this: a measure must be of the same genus as what is measured, as stated in *10 Met.*, T. 7, 4, and the manner of enduring of both must be uniform — either permanently or successively — and weight is measured by weight and a table by a cubit; but the substance of an Angel is measured by the aeon because it is permanent; therefore likewise its immanent operation is measured by the aeon because it is permanent, even though this has an end while the substance does not. For if God were to create an Angel that endured by the aeon as long as it existed, and if God were then to annihilate it, its substance would have an end, and yet it would not prevent it from having endured by the aeon; therefore even though the immanent operation of an Angel is terminated, nothing prevents it from being measured by the aeon. Moreover, if a substantial form were always to inform matter, it would be measured by the aeon; therefore it is also measured by the same measure of the aeon even if it is separated from matter, because it possesses the same mode of existing and enduring, whether it inheres in matter or is separated from it. Furthermore, if a motion were never to end, it would be measured by time; therefore if a permanent being has an end, it is likewise measured by the aeon. The consequence holds because the former is measured by time because it is successive, and therefore the latter is measured by the aeon because it is permanent. Again, the Angel is placed in the category of substance, as stated in *5 Met.*, T. 15, because it is a finite substance; therefore its measure resides in the category of quantity, because it is likewise finite and not transcendent, as Cajetan thinks. But such a measure is not continuous time; therefore it is the aeon. Furthermore, discrete time as devised by the Thomists is composed of its instants, since it means nothing other than several instants of it joined and aggregated together, according to them; therefore continuous time too would be composed of indivisibles, since the same reasoning applies to both — but they themselves do not admit this, and therefore they ought not to concede the other either.

Objection I: St. Augustine in *4 Super Genesim ad litteram*, c. 11, and *5 of the same work*, c. 21, cited by the Coimbrans in *art. ult.*, *4 Phys.*, *in margine*, seems to indicate discrete time, saying that God moves the spiritual creature through time; therefore, besides continuous time, another measure must be found according to Augustine, by which the operations of Angels are measured, and this is called discrete time. Scotus replies that Augustine there takes time for anything whatever that can have being after non-being, in which sense everything other than God can be called temporal, since everything created previously was not, and after creation, is. I therefore deny the consequence. For Augustine asserts nothing there that favors the Thomists.

Objection II: Some things are measured by eternity, such as God, who is without beginning and end; some are measured by the aeon, such as the Angel, which has a beginning but lacks an end; others are measured by time, such as successive and continuous motion; but the permanent and immanent operations of the Angels remain, which are not measured by eternity because they have a beginning, nor by the aeon because they have an end, nor by time because they are permanent; therefore another measure must be devised by which they are measured, which is called discrete time. Reply: the permanent operations of the Angels endure by the aeon, which is the measure of every created being whether it always persists or at some point fails; while the transient operations endure by continuous time, which is the metric and measure of all successive things.

Objection III: After the day of judgment time will be no more, as stated in *Apocalypse X*, because the primum mobile and the other Heavens will move no more; but the operations of the Blessed will endure — not by continuous time, because there will be none; therefore by discrete time, which is their measure. I reply that there will then be no extrinsic and universal time, but quite rightly intrinsic and particular time, which measures the operations of the Blessed both before and after the universal judgment. Or say that these will endure not by positive but by privative time, just as when motion ceases, rest — which is its privation — is said to be measured by privative time; and similarly motion itself, if it were to occur in a vacuum while all other motions had ceased.

Question II. On Things Subject to Time.

Article I. Which Things Are in Time.

This difficulty is examined by philosophers under another title, namely, which things are measured by time; and to be in time is the same as to be measured by time, according to Aristotle in *4 Phys.*, *T. 114*. It is certainly the case that God is not in time, since eternity is His measure — as Augustine expressed in *2 De Moribus Manichaeorum*, *c. 1*, saying: "God is not subject to time." Nor is the Angel measured by time, because it endures by the aeon, as stated in *1 Caeli*, *T. 100*. Nor likewise is the Heaven and all incorruptible permanent things, for the same reason. The whole controversy is about generable and corruptible substances. The affirmative part is defended by Thomas in *1 p.*, *q. 10*, *art. 4*, *ad 3*, Cajetan in the same place at *a. 5*, Soncinas in *10 Met.*, *q. 54*, Fonseca in *5 Met.*, *c. 13*, *q. 12*, *sect. 4*, and Tolet in *4 Phys.*, *q. 15*. The negative is championed by Scotus in *2 d. 2*, *q. 4*, §. *Concedo*, and in *Rep. ibid.*, *q. 1*, Suarez in *disp. 50*, *Met.*, *sect. 1*, Canon in *4 Phys.*, *q. 8*, Bonetus in *6 Phys.*, *c. 3*, Ruvio in *Tract. de tempore*, *q. 1*, Fuentes in *q. 3*, *3 diff. 2*, *art. 2*, and many others.

Note from the Doctor in *cit. B.* that corporeal substance can be examined in two ways: first, in itself, as it abstracts from motion and flux, and in this way it is permanent, having its whole being simultaneously; second, as it is subject to

motion, change, and other accidents that follow upon it and accompany it, in which way it is called mutable, fleeting, and temporal. All of this can be illustrated from the Heaven, which is of itself permanent and incorruptible, yet mutable through the motion by which it is always rotated from east to west. By reason of the first, the heaven endures by the aeon, which as has been said is an indefectible, permanent, and wholly simultaneous measure; but by reason of the second, it is measured by time, which is a successive measure having prior and posterior parts. What causes difficulty in the present matter is this: the generable and corruptible substance — especially the animated — at one time grows and at another decreases; some of its parts are generated and acquired through nutrition, while others that previously existed flow away and are lost; and finally the whole perishes and dies together. Hence it seems to be in time, which is said to consume and destroy all things; yet since it has its whole being simultaneously, it does not seem to be subject to time, because the permanent and the successive adequately divide continuous quantity, just as species divide their genus — as man and brute immediately and adequately distribute animal — and therefore the measure proper to the permanent ought to belong to it, which is called the aeon.

Assertion: Generable and corruptible substances are measured not by time but by the aeon. So holds Scotus in the passages cited above. The first part is urged: first, from *4 Phys., c. 12, T. 118, 119*: a mobile body is not in time as something quantified, but as the motion is quantified; therefore according to Aristotle, a corporeal sublunary substance is measured by time insofar as it has motion annexed to it, which is measured by time per se, and not as a substance existing with a permanent continuous quantity. The Coimbrans object that substance in itself lacks any measure; and so Aristotle says that a mobile body is not subject to time except insofar as it is subject to motion, by reason of which the same Philosopher admits that the sublunary body is in time. But these authors do not rightly weigh the text of the Philosopher, since Stagira does not write absolutely and precisely that a mobile body is not measured by time, but expressly says "as something quantified"; and since continuous permanent quantity, such as body, has its own measure, they therefore do not rightly expound the text, nor do they in any way dissolve the argument opposed to them. Fonseca in the passage cited replies differently, and says that a generable and corruptible body is always moved by at least an improper motion, which is the flux of its parts, which are acquired through nutrition in place of those that have been lost and previously existed in it; and for this reason, through this kind of motion and flux, it is in time, by which it suffers and is ultimately consumed. But this reply does not accord with the passage cited. For Stagira there denies that a body as quantified is measured by time; therefore such a body has no motion, even improper; for whoever removes what is posterior in actuality also removes what is prior in actuality, from which the former necessarily flows. Therefore since Aristotle takes away time from the said body — which is

posterior to motion — he consequently removes the motion itself as well, which is its cause. For when the subject is removed, its attribute is removed along with it: just as if risibility is removed, rationality is also removed; and since time is an attribute of motion, as stated in *8 Phys., T. 11*, when time is removed from a quantified body, the motion measured by time is also taken away. I add that the distinction offered by the Philosopher would be pointless: for if a body as quantified is measured by time, and the same body equally has the same measure of time as it participates in quantified motion, what would be the purpose of distinguishing the body as quantified and as having quantified motion? It should rather be said that on both views the body is measured by time — which is not what Aristotle asserts, since he teaches that a body simply as quantified is not measured by time. Second: a measure is of the same genus as what is measured, as stated in *10 Met., T. 4*; but a sublunary body is something quantified by a permanent quantity, since it is wholly simultaneous, having its parts simultaneously joined at a common boundary; therefore its measure is permanent, not successive as time is. This argument is so powerful that it led Thomas in *opus. 44, de tempore, c. 3* to our aforementioned assertion, as is clear from his words adduced by the Coimbrans in the cited passage at §. 1 — though Masius denies that that opusculum is Thomas's. But since it bears the stamp of his style, this should not be denied; rather it should be said that the force of the argument changed his opinion, as happens to him in some other matters, and as neither Augustine nor other holy and learned men blush to abandon stubbornness and tenacity in their opinions, adhering instead to reason and truth. The Coimbrans add, in order to satisfy the argument adduced, that sublunary and corruptible substances are subject to time because they are mutable and transmutable, being in a perennial flux of parts, some of which depart while others arrive and succeed. Against this: the whole substance possesses a permanent quantity, as is plain in man and stone; therefore its measure is not time, which is wholly, intrinsically, and essentially successive. Moreover, that substance is measured by time insofar as it is subject to motion and change, as those authors themselves admit; therefore not by reason of the substantial quantified substance, but by reason of quantified motion, does it have a temporal measure — which is the assertion of Aristotle, Scotus, and the others whom they are refuting. Again, although some of its parts flow away, the whole persists; and therefore it is not measured by time, just as even if some parts are removed from a stone or a tree, it is still the same stone and the same tree continues permanent, to be measured by the same measure as before, when it was constituted by those parts. Furthermore, gold and other metals whose parts almost all remain, stones, and the bodies of the Blessed after the day of judgment will always persist in their being without any flux of parts, yet they will not be subject to time, nor be contained or dominated by it; therefore neither are they now measured by it, since they always have the same measure, because they are always permanent, and the measure of permanent things is not time.

The second part is against Suarez and Ruvio cited above, and is held for Scotus and the Scotists in the passages just cited. It is proved thus: first, every measure is either eternity, or the aeon, or time, from what was said in the preceding article; but sublunary substance is not measured by eternity, as is plain, nor by time, as I showed in the first part of the assertion; therefore it is measured by the aeon. The adversaries object that a corruptible body does not deserve the aeon as its measure, since the aeon is proper only to those that are incorruptible and immortal, perpetual and without end — not to the sublunary substance, which comes to an end and is destroyed. But this does not prevent the said substance from being measured by the aeon, since just as every successive thing is measured by time — even if one lasts little and another very long — so every permanent thing is measured by the aeon, even if one endures perpetually and another is quickly destroyed and perishes. Again, if motion were eternal as Aristotle thinks, it would be measured by time, and it has the same measure of time among us, since it is in reality to end; therefore every permanent thing has the aeon for its measure, even if some are perpetual and incorruptible, such as the Heaven, and some are corruptible and subject to end, such as sublunary substance. Again, if an Angel were annihilated by God and the Heaven destroyed by the same, nevertheless the measure of each would be the aeon, even if each had an end; therefore likewise sublunary substance endures by the aeon even as it wastes away and perishes; and so Scotus appropriately and aptly names the measure of generable and corruptible substance the aeon.

Objection I: Aristotle in *4 Phys.*, *T. 20* explicitly says that those things are in time and are measured by it which are grasped, overcome, and dominated by it, as well as those that are generated and corrupted; but sublunary substances are generated and corrupted; therefore their measure is time. Reply: the major must be expounded through distinction; if sublunary substances are taken with respect to their substantial and quantitative permanent being, I deny — for in this way they have their whole being simultaneously, and all their parts are simultaneously joined by a common boundary; but if they are taken with respect to quantified motion, which is conjoined to them, I grant. For in this way they are measured by time on account of motion, which is immediately and per se measured by time. This reply and distinction is Aristotle's at *cit. T. 118*, which I explained and adduced at the beginning of our assertion, and it is confirmed by Scotus in the passage noted and in *11 Met.*, in the exposition of *c. 3, sum. 1*.

Objection II: Living natural things are said to live for so long a time and then to die, as in *Genesis V*: "The whole time that Adam lived was nine hundred and thirty years, and he died." And shortly after: "All the days of Seth were nine hundred and twelve years, and he died." And so for the rest, in whom youth and old age, novelty and old age, life and death are distinguished; therefore sublunary bodies, and above all living things, are measured by time. Reply: according to the distinction offered, the animate and all other natural generable and corruptible beings are subject to time not according to their substantial and

quantitative permanent being, but according to the motion that is conjoined to them, which is per se subject to time. This is confirmed from the Heaven, which is not measured by time as an incorruptible substance, but through the motion annexed to it, by which it is moved continuously and successively.

Article II. Whether There Is One and the Same Now throughout All of Time.

This difficulty arises from Aristotle in *4 Phys.*, *T. 104*: "In all of time the now is the same according to substance, but different according to being." Since this is obscure and difficult to understand, its interpreters diverge into various senses and opinions. Aureolus in *2 d. 2, art. 5* thinks that there is really one now throughout all of time, differing only according to disposition and character. Not far from this view seem to be Albert and Thomas, as cited by Tolet in *4 Phys.*, *q. 14*. Others, whose name Aureolus suppresses in the cited place, think that there is one now by unity of subject in which it subsists. But others, among whom are Scotus in *3 Met.*, *at the end of the exposition of T. 17*, and *2 d. 2, q. 2, §. Istam instantiam*, and in *Rep.*, *q. 1*, Antonius Andreas in *3 Met.*, *q. 3*, Canon in *4 Phys.*, *q. 6*, Bonetus in *6 Phys.*, *c. 1*, Tolet cited above, and Ruvio in *the first Tract. de tempore*, *q. 2, dub. de instanti* — these teach that there is one now quasi specifically but many numerically in all of time.

Note first that to be the same according to substance is the same as to be the same in itself and considered absolutely, while to differ according to being means nothing other than that the same is compared to diverse things — according to the interpretation of Lychetus in the passage noted from Scotus in the same place; for the now or instant takes on diverse comparisons insofar as it is the end of the past and the beginning of the future, as Aristotle notes in *4 Phys.*, *T. 106*; or, as Bonetus in the cited place expounds, to be the same according to substance means the same essence and quidditative and specific character — in which sense it is taken in *1 Praedicam.*, *c. 1*: "Univocal things are those whose name is common and the account of substance according to that name is the same." To differ according to being designates the individual and singular being, which is multiple, in accordance with multiple individual differences. Hence in time the now is the same specifically but multiple numerically.

Note second from Aristotle in *the passage cited at T. 126* that the now can be taken in two ways: sometimes for the proximate time in which something has been done or is to be done, in which sense it is frequent among men — "Peter is just now arriving" or "Peter will arrive just now." This is confirmed by Augustine in his commentary on *Psalms 55*, where, speaking of Job tempted by the devil, he says: "The tempter was permitted to tempt the holy man Job; in one instant of time he took away everything" — that is, he lost everything in a short time. And in *tract. 107 in Joan.*: "Do we not say every day, 'He is no longer here,' of one who is about to depart very soon?" By contrast, what happened a long time ago we by

no means say happened now — for example, we do not say "Christ was just now born" or "Christ was just now crucified." Properly speaking, however, the now is taken for the instant of time, which mediates between the parts of time, uniting and joining them together — just as a point is placed between the parts of a line, joining and uniting them — and it is this second kind of now that is being discussed in the present context.

Assertion: In all of time there is one now quasi specifically but many that are numerically distinct. So holds the Doctor in the passages cited above, and this is the genuine meaning of Stagira in *cit. T. 110*, who admits several nows in time. And more clearly in *3 Met., at the end of T. 17*: if according to the opinion of the Philosopher there are several nows numerically in time, then according to him there is one now specifically. Now it is proved thus: first, if there were only one now numerically in all of time, all things would be in the same now, and those that existed from the beginning of the world and those that are yet to come until its end would exist simultaneously, since they would be under the same numerical now; but how empty, false, and absurd this is, is plain to all; therefore there is not one now in all of time, but one specifically. Second: the same reasoning must apply to the now with respect to time as applies to a point with respect to a line, and to the "having-changed" (*mutatum esse*) with respect to motion, as Aristotle infers in the passage just cited; but several points are located numerically in a line, and several instances of having-changed are in motion — since between two parts of a line a point mediates, and between two parts of motion a having-changed is present; therefore likewise between two parts of time a now or instant intervenes; but there are several parts of time, and therefore also several nows or instants, yet one now and instant specifically. Third: when the subject is multiplied, the attribute that flows from it is likewise multiplied, just as when man is multiplied, risibility — which is his property — is likewise multiplied; but in motion the instances of having-changed are multiplied, since between two parts of motion a having-changed is present; therefore the now is likewise multiplied, since it follows upon the having-changed as an attribute follows upon its subject from which it proceeds. And thus there are many nows numerically, yet one specifically. Add: if there were only one now in all of time, it would be co-extensive with time itself — for time is one, and therefore one instant would also exist; but it cannot be that the now, which is indivisible, should be co-extensive with the whole of time, which is divisible to infinity; therefore it is likewise impossible that there should be only one now in all of time.

Objection I: Aristotle in the cited *text 101* seems explicitly to assert that there is in all of time only one now numerically, because the now produces time, just as a point produces a line, and he illustrates this with the example of Coriscus, who is one and the same numerically, even though he successively exists in the house and in the forum. He always remains substantially the same, even though he changes accidentally; similarly the now is always the same in time substantially,

even though it differs according to various relations and accidents. Reply: besides the interpretation already offered, which is more conformable to Aristotle and closer to the truth, as Bonetus in the cited place attests, it can also be said that the Philosopher speaks there in the manner of the Mathematicians, who think that a point flows through a line; so too the now he indicates traverses time, just as Coriscus at one time seeks the house and at another time ascends to the theatre — and similarly the now is related to the past, of which it is the end, and to the future, of which it is the beginning.

Objection II: Unless the same now persisted throughout all of time according to substance, it would certainly be corrupted; for the same thing either persists or is corrupted: but it cannot be corrupted — for it would be corrupted either in itself or in another instant, and this either preceding or subsequent, either immediate or mediate; but it cannot be corrupted in any of these ways: not in itself, otherwise it would both be and not be simultaneously; not in a preceding instant, otherwise it would be corrupted before it existed; not in an immediately following instant, since there are no immediately consecutive instants; not in a mediate instant, because between two instants there is a part of time — therefore the same now remains in all of time. Reply: generation and corruption properly belong to sublunary substance, as I noted elsewhere, and its production is measured by the instant; but an instant is not measured by an instant, just as time is not measured by time, since a measure differs from what is measured. Therefore the now and other indivisibles are said to begin and cease to be, for inception and cessation of things have a broader application than generation and corruption.

You will ask: is time the cause of the corruption of things? The common view holds that time overturns and devours all things, and thus time is called "time the devourer of all things" (*tempus edax rerum*). But time is not per se the cause of their corruption, since it belongs to the genus of quantity, which is not active; but per accidens, insofar as things that endure through time or coexist with time are corrupted either by an intrinsic principle — through the extinction of natural heat or the consumption of the radical moisture — or from without, by water or fire, concerning which we have daily experience of the coming-to-be and perishing of sublunary things; and this is indicated by Aristotle in 4 *Phys.*, T. 128. I do not omit the admonition of St. Augustine in *De verbis Domini*, *serm.* 39: "The days themselves, hastening, pass away, because this day has shut out yesterday; the days themselves do not stand still — why do you wish to stand still with them?" And in *De verbis Domini*, *serm.* 42, according to John: "Words run on and hours fly; so does our life, so does this happiness of ours — all our time passes away, and the Word of the Lord abides forever."

Book VIII. On Motion.

Aristotle treats of motion both in *3 Phys.* and in *5 of the same work*, since it is the principal attribute of a natural body, and without a knowledge of it, nature itself is unknown, as the same Philosopher warns at the beginning of *3 of the cited book*. And it is of use for investigating the Intelligences that move the celestial orbs, and for attaining knowledge of God most good and great, who is the beginning and end of all motion. For in Him we live, and move, and have our being (*Acts XVII*).

Question I. On the Nature of Motion.

Article I. Whether Motion Exists.

Although it is clearer than light that motion exists, nevertheless, on account of the objections — or rather the quibbles — of Zeno, which will be dissolved below, the present article is established. For Zeno himself, as Aristotle reports in *8 Top.*, *c. 3*, and *6 Phys.*, *c. 1*, *T. 75*, denies that motion exists; against whom stand Aristotle just cited and all the other Philosophers who admit motion, with whom the assertion is made.

Assertion: Motion exists. This is presupposed by the Doctor in *9 Met.*, *quaest. 14*, and *11 of the same work*, *sum. 4, cap. 1, in com.*, and in *2 dist. 2, quaest. 9*, and in *Rep.*, *quaest. 2, primi dist. 2, §. Ad 2. rationem*. It is evident to the senses and visible to the eye. For celestial and sublunary things are seen to move every day; and so a certain person said against Zeno, who denied motion, that argument is not to be used against him, but walking. Indeed, if anyone were now stubbornly to refuse to admit motion, he should be struck until he confessed that the one striking him was moving the rod to beat him. Moreover, each thing possesses its own power for attaining its own end; otherwise such a power would be superfluous. Hence the common saying: "A power that is not reduced to act is pointless." But a natural body possesses the power of moving itself from place to place. For since all natural things are of finite and limited perfection, they consequently move to acquire for themselves the good and perfection they lack — as an ox moves toward eating hay, a lion toward devouring flesh, a horse toward oats, man toward gold, and so with the rest; therefore motion is manifest, and it is better presupposed than proved. I add with Scotus in *4 dist. 12, quaest. 2, §. Quantum ad istam, ante A.*, drawn from *5 Phys.*, *Summ. 2, cap. 1, T. 26*: it is foolish to seek a reason where we have something more certain than reason, such as true sensation and indubitable experience. Hence the same Doctor in the *Reportatio* cited above places the existence of motion among per se known contingent propositions.

You will object first: if motion existed, the mobile would traverse, in finite time, an infinite space; but the infinite is not traversable, as stated in *3 Phys.*, *40*; therefore there is no motion. The consequence of the major is shown: if a

mobile is moved through some space, it is necessary that it traverse all the parts of that space; but the parts of space are infinite, because space is divisible into other and yet other parts to infinity. I deny the consequence of the major; to its proof I say that space is traversed by a mobile in terms of its aliquot parts, which are of determinate and finite quantity — by reason of which the space is called great or small — and not in terms of proportional parts, which are always divisible and to which one never arrives at a last one. Therefore Zeno's argument is inconclusive, for it passes from aliquot parts to proportional parts, which is a manifest sophism.

You will object second: if motion existed, a mobile could be moved either in the terminus from which or in the terminus toward which; but it can be moved in neither way; therefore motion is not to be admitted. The major is urged: it cannot be moved in the terminus from which because motion begins from it, nor in the terminus toward which because motion ends in it, and it cannot be in both termini simultaneously since it cannot be in two places at once, nor in neither of them since it moves from one to the other. Reply: the mobile is moved on the way, that is, in that interval that lies between the terminus from which and the terminus toward which; motion begins from the terminus from which and ends at the terminus toward which. The remaining objections raised by Zeno and others may be seen in Aristotle cited and his interpreters — objections so thoroughly overthrown and defeated that no one any longer has the will or the right to vindicate them from destruction.

Article II. What Motion Is.

The nature and essence of motion seems to be deeply hidden and difficult to grasp, as Aristotle indicates in *3 Phys.*, *Summ. 2, cap. 5, T. 12*, from the variety and multiplicity of opinions of the ancient Philosophers in transmitting, assigning, and explaining the definition and quiddity of motion. For some suspect motion to be alteration, some diversity, others inequality, and there are those who would have it be a non-being. Others, however, with Aristotle in the passage cited at *T. 6, cap. 2*, teach that motion is the act of a being in potency as it is in potency; and at *T. 16*, that motion is the act of the mobile as the mobile is; and at *T. 23*, that motion is of that which can act and be acted upon, as such. These three definitions of motion mean nearly the same thing and are apt, but the first is more celebrated, more precise, and better, and is therefore to be received, held, and defended against the darts of adversaries by which it is assailed.

Assertion: Motion is rightly defined as the act of a being in potency as it is in potency. So holds Scotus with Aristotle in *1 Met.*, *T. 8, sum. 4, cap. 1*, and in *Quol. 3, H*. It is explained before being proved. "Act" means an inchoate and imperfect action, as the same Aristotle explains in *3 Phys.*, *5*: for the mobile moves toward acquiring something, and therefore motion, which is the way and tendency toward that thing, is aptly an act or operation begun and imperfect. "Of a being" is added — namely, a physical being, or natural body, as Aristotle indicates in *5*

Phys., T. 10, and in *11 Met.*, *sum.* 4, T. 8, where Scotus in his commentary also notes: for the subject of motion is an existing natural body, from which mobility as its principal attribute flows. "In potency, as it is in potency" is subjoined, because the mobile has the potency toward that which it actually lacks, and insofar as it participates in such potency it is moved to acquire it for itself. For this reason God, who has all things and is most actual and most perfect, is subject to no motion. The definition of motion explained in this way is then urged as follows: first, an adequate definition is one that consists of genus and difference, as I have urged more than once above; but the above-given definition of motion is of this kind — for "act" is its genus, and the remaining terms serve as its difference; therefore it is a correct and adequate definition. Second, it is proved by Aristotle through induction across the individual motions: for there are six principal motions mentioned by Stagira in *Postpraedicam.*, *cap.* 14 — alteration, generation, corruption, increase, decrease, and local change; and all of these individually participate in the stated definition of motion, so that alteration is the act of what is alterable as it is alterable, generation is the act of what is generable as it is generable, and so with the rest; therefore the definition of motion is well given.

Objection I: The definition just given does not include every motion; therefore it is not a good one. The antecedent is proved: intellection and volition are indeed motions, but not of a natural body but of an intellectual nature. And likewise these operations belong to God, who succumbs to no motion. I deny the antecedent. To its proof I say, with Aristotle in *9 Met.*, T. 16, that those operations are not properly motion in the sense in which we speak of motion here, but rather are the terminations and ends of the powers of the intellect and will — especially in God, since they are really identical with Him; and they pertain to man insofar as they proceed from the rational soul, which is an intrinsic and essential part of man himself, who is contained under natural body.

Objection II: If motion is an act, which in Greek is called *entelecheia*, then since the soul is an act, the soul will be motion — which is false; therefore motion is not an act as stated above. Reply: motion is a second and formally accidental act, while the soul is a first and substantial act. *Entelecheia* is a name common to both of the aforementioned acts. Hence Scotus in the cited passage at *11 Met.* notes that the name *entelecheia* placed in the definition of motion means nothing other than the way to perfection, or to the good, toward the acquisition of which the mobile is moved.

Article III. Whether the Stated Definition of Motion Applies to Every Motion.

Fonseca in *5 Met.*, c. 3, q. 9, *Sect.* 1, Pererius in *lib.* 13, *cap.* 5, Andun. in *5 Phys.*, *quaest.* 2 & 3, and the Coimbrans in *3 Phys.*, *cap.* 2, *quaest.* 1, *art.* 1, hold that the stated definition belongs only to successive motion. But Scotus in *quaest.* 44

Praedicam., Antonius Andreas in *11 Met., quaest. vn.*, Canon in *5 Phys., quaest. 2, artic. 3*, Parisiensis in the same place at *quaest. 1, fol. 59*, Fuentes in *3 Phys., diff. 2, artic. 1*, and the Coimbrans in *disp. 16, quaest. 2, §. 2, num. 16* include under this definition every motion, both successive and instantaneous.

Note from the Doctor just cited that motion can be taken in two ways: first, generically, as it abstracts from every change whether momentary or temporal; second, specifically, for successive motion only — about which Aristotle speaks in *5 Phys., cap. 1*, and in *11 Met., sum. 4, cap. 3*, where he denies that generation is a motion, with which the Doctor agrees both there and in *2 d. 12, q. 1, §. Ad argumentum*.

Assertion: The definition of motion given above agrees with both successive and instantaneous motion. So holds the Doctor in the *Praedicam.* cited. This is urged first from Aristotle, who in *3 Phys., T. 6* illustrates the said definition of motion by examples from instantaneous motion — such as generation — and from successive motion, such as alteration; and earlier in the *Postpraedicam.* he presents six species of motion, among which he places generation — which is sudden motion — and alteration — which is temporal motion; therefore according to Aristotle the present definition includes both successive and momentaneous motion.

You will say, with Fonseca cited, that generation can be taken in two ways: either for the preliminary dispositions necessary for generation itself, or for the introduction of the substantial form into the pre-existing matter — and this is instantaneous, about which Stagira does not speak in the passages noted, but about what precedes it, which is a successive temporal process and which coincides with alteration. Against this: alteration and generation differ from one another as two species contained under the same genus, as Aristotle states in *Postpraedicam.* cited; therefore, since the same Philosopher in *3 Phys.* cited enumerates those very species of motion and gives examples of each, he does not take one for the other, but since they are distinct from each other, he offers distinct examples of them as distinct.

You will say, with Scotus in the present *quaest. 1*, that Aristotle there speaks of generation not properly and formally as generation is, but of its terminus, which is preceded by alteration — and so he first placed alteration, which is followed by generation taken as the terminus itself, which is produced in an instant and by which it is specified. Against this: the terminus of generation is extrinsic to generation itself, just as the terminus of any other motion is extrinsic to it, since the terminus is posterior to the motion — for motion is the way and tendency toward the terminus. Therefore, since Aristotle speaks of motion formally taken and gives examples of its species, he does not discourse about the terminus of generation nor adduce examples from the termini of the other motions — as can be seen in *T. 11*, where he distinguishes building, which is motion, from its terminus, which is the house; and in *T. 22* he distinguishes teaching, which is

motion, from learning, which is its terminus. And he does the same with generation, whose terminus is the substantial form produced in matter. Moreover, each motion has its own terminus distinct from that of the rest — alteration has quality, increase has quantity, and generation has the form drawn forth or introduced — and thus Stagira does not use "generation" for its terminus. Second: in the text cited, the Philosopher speaks of motion, and notes there at *T. 1, 2, Phys., T. 1* in the definition of nature that he will treat of motion in those places; and there he treats of motion taken universally, abstracting from simultaneous and successive motion, whose nature is the principle of both; therefore the definition given of it befits both; otherwise another general definition of motion common to both would need to be given, whereas none other has been given by him; and indeed in *11 Met., sum. 4, cap. 3*, where the Philosopher speaks of motion universally and of its individual species, he offers the same definition of motion that he had given and explained in *3 Phys., T. 6*. Moreover, the said definition is correctly adapted to both instantaneous and temporal motion: for in truth generation is the act of what is generable as it is generable, just as alteration is the act of what is alterable as it is alterable.

You will say: in the passage of the *Met.* just cited, Aristotle expressly denies that generation is properly a motion; therefore generation and any other instantaneous motion are not included under that definition. The reply must be that the Philosopher there removes generation from the series of successive motions, as he had already done in *5 Phys., T. 5*, and as I noted in the preceding note.

Objection I: From *3 Phys., T. 1*: motion belongs to the genus of continuous things, not indeed of permanent ones, but therefore of successive ones; the same is found in *4 of the same work, T. 99*, and in *5 Met., T. 18*; therefore the definition just given is adapted only to successive motion. Reply: Aristotle said this because successive motion is more open and evident, and did not deny that generation and the other species enumerated above are contained in the said definition, since he himself says there that if motion is unknown, nature is also unknown — but it is certain that nature is the principle and cause not only of successive but also of instantaneous motion.

Objection II: To be an act in potency as it is in potency suggests that motion is partly being done and partly yet to be done; but being done and yet to be done imply succession; therefore that definition is adapted only to successive motion. Reply: by those words it is only designated that motion is an inchoate and intrinsically imperfect act, looking toward a more perfect act. Hence God alone is immobile, because He alone is perfect; while other things are mobile and tending toward further perfection, whether substantial or accidental.

Article IV. Whether Motion Is Something Absolute or Relative.

Many who admit motion are divided into two camps: some think it is something absolute and locate motion in the genus of quantity, holding it to be a species of successive quantity; others think it is a certain absolute mode, as they judge concerning the six last predicaments, of which I made mention in *Log., lib. 3, q. 5, art. 1*. Scotus, however, in *2 d. 14, q. 2, §. Ad 1 arg. L.*, and in *Rep. ibid.*, and in *4 d. 13, q. 1, §. Ad huius autem*, Mayr in *2 d. 8, q. 2*, Ballesteros in *4 d. 48, q. vn.*, Vorrilong in the same place at *d. 10, termino 2*, Joan de Magistris in *3 Phys., q. 2*, and Parisiensis in that place at *§. In oppositum, fol. 47*, affirm that motion is a relative being.

Note first that in every motion two principal termini intervene: the terminus from which and the terminus toward which. The terminus from which is where motion begins; the terminus toward which is where motion ends. Then, some termini are primary — such as a habit and its privation; others are concomitant, which follow upon the primary termini and which occur in the augmentation of a quality. For the degrees that follow upon a quality in its increase, such as five or six, are called concomitant termini; the primary termini are mutually impossible in the same subject, while the concomitant ones are compossible.

Note second that motion can be taken in two ways: first, materially — that is, for the form acquired or to be acquired through motion; second, formally — that is, for the relation coming to the mobile from without with respect to the mover. In order that this may be better understood, note that six entities are found in any motion: the first is the mover, the second is the mobile, the third is the flowing form, the fourth is the flux of the form, the fifth is the relation coming from without of the mover to the mobile, and the sixth is the relation coming from without of the mobile to the mover. Now the question is which of the aforementioned entities is formally motion.

Assertion: Motion formally is not something absolute but is the relation coming from without of the mobile to the mover. The Doctor transmits this in the passages noted. This is urged first: what is absolute is what is in relation to itself, while what is relative is what is carried toward another, as I explained at length in *Epit., lib. 1, quaest. 1, art. 6*; but motion is toward another — for it is the way and tendency toward the terminus toward which, as I noted above; therefore motion is a relative being. Second: motion is described as the act of a being in potency as it is in potency; but act or action is a relative form, belonging to the genus of action and coming from without, as I taught in the passage noted at *quaest. 4, art. 10*; therefore motion is the stated relation. This reason is intimated by Aristotle in *3 Phys., T. 11*, who calls the motion of building an action, which is the act of building; and in the same place at *T. 27, 22* he calls the motion of teaching a "teaching" (*doctio*), which likewise is an action residing in the predicament of action; and in *5 Phys., cap. 1, T. 5* he names the motion of whitening a "whitening" (*dealbatio*), which is equally an action of the same genus. Third: motion is not the mover, because that is its cause; nor is it the mobile,

because that is its subject; nor is it the flowing form, since this can exist without the former, as whiteness can exist without actual whitening, as Stagira explicitly writes in the passage just cited; nor is it the flux, since flux includes succession, which does not belong to the intrinsic character of motion, as will be said in the following article; nor is it the relation of the mover to the mobile, since otherwise, as God is the mover of all things, motion would be in God — which is false. It therefore remains that motion is the relation coming from without of the mobile to the mover.

Objection I: Aristotle in *5 Met.*, *T. 8*, and Scotus in the same place and in *Quol. 11*, place motion in the category of quantity; but what is located in that predicament is absolute; therefore motion is something absolute. Confirmed from St. Augustine in *lib. 83, quaest., quaest. 35*: love is a certain motion; but love is an absolute being, since it belongs to the genus of quality; therefore so is motion. Reply through explanation and distinction of the major: Aristotle and Scotus speak there of motion materially taken — that is, for the form acquired or to be acquired through motion, as I noted in the second note. For that reason the same Philosopher treats of motion and its species in the *Postpraedicam.* but not of motion formally taken, of which I now speak. The same is to be said of the confirmation. For Augustine there subjoins that motion is toward something, intending to indicate to us that love is indeed a quality if its motion is taken materially, but is a relation if it is taken formally.

Objection II: Motion implies some perfection: for those things that are moved are moved for the sake of acquiring some perfection; but relation implies no perfection; therefore motion is not the stated relation. I grant the major and distinguish the minor: relation does not imply perfection simply speaking, I grant; in a certain respect, I deny. And especially because it suffices that through motion there be acquired an absolute form that includes perfection. Hence in the divine, the relations of origin formally designate no perfection, but really they do, since they are really identical with the divine essence, which is the infinite sea of all perfections.

Objection III: What is the cause of an absolute thing is itself absolute, since an absolute thing is produced and caused only by an absolute thing, and a relative thing is too imperfect to be the cause of an absolute thing and for the absolute to depend essentially on it, as Scotus states in *2 dist. 14, quaest. 2 in fine*; but motion is the cause of something absolute — hence we have that frequently repeated saying, "motion is the cause of heat," and the Heaven is said to exert influence on these inferior things principally through motion; therefore motion is to be expelled from the genus of absolutes. I grant the major and distinguish the minor: per se, I deny; per accidens, I grant — in roughly the same way as I said above that time is not per se but per accidens the cause of the corruption of natural things, as Joan. de Magistris holds in *1 Meteor., quaest. 3, dub. 2*.

Article V. Whether Succession Belongs to the Essence of Motion.

Some, whom Raconius follows in *disp. de motu, quaest. 2, propositione prima*, and whom two of our recent authors support in *disp. 5, quaest. 1*, assert that succession enters the essence of motion. But Scotus in *2 dist. 2, quaest. 9, §. Ad argumenta post L.*, to whom his interpreters adhere in the same place, and among the recent authors Tolet in *5 Phys., q. 1*, the Coimbrans in *3 Phys., c. 2, quaest. 2, art. 3*, Fonseca in *5 Met., cap. 13, quaest. 8, sect. 3*, and Suarez in *disp. 49, sect. 2 & 4* does not dissent — these all deny that succession is included in the essence and nature of motion.

Note that this difficulty is discussed about motion taken generically; for about motion taken specifically there is another question, particularly about local motion, to be examined and decided below in *quaest. 3, art. 2*. Moreover, it should be recalled from what was said that the succession of motion can arise in two ways: either from the divisibility of the mobile, which is continuous and divisible into prior and posterior parts; or from the divisibility of the space to be traversed, which is continuous and has parts after parts divisible to infinity.

Assertion: Succession is not of the essence of motion, nor is it its attribute.

This is deduced from the Doctor cited above and follows from what was said in *quaest. 1 of this book, art. 3*, in which I established that the definition of motion belongs to every motion. The first part is proved thus: first, from Aristotle in *3 Phys., T. 6*, who proves the stated definition of motion by induction from alteration — which is successive motion — and from generation — which is instantaneous motion; but if succession were enclosed in the essence of motion, the definition would undoubtedly not be adapted to generation, which is sudden; therefore etc. Second: God, when He works miracles, does not take away the essences and natures of things but preserves them whole and unharmed, as is plain from the Babylonian fire and from the sea upon which Christ walked; but God can bring about motion without any succession — as in the Scotist school, when the body of Christ is brought from heaven into the consecrated host in an instant, with the pronunciation of the words of consecration — therefore motion is not essentially successive. Third: by divine power what is prior can be separated from what is posterior, provided the latter does not depend essentially on the former — as substance depends on the accident that inheres in it; but motion precedes succession, as I inferred above, nor is there any essential dependence between them, since motion can be without succession and abstracts from the successive and the instantaneous; therefore succession is not intrinsic and essential to motion.

The second part is evident: for an attribute, according to Scotus in *2 dist. 16, quaest. vn.*, is really identical with the thing of which it is an attribute and is inseparable from it; but motion, from what has been said, can exist without succession; therefore succession is not its attribute. Moreover, an attribute that proceeds from the essence of a species is not an attribute of the genus — as risibility, which is an attribute of man, is not an attribute of animal; otherwise, if

it belonged to animal generically taken, it would likewise belong to all the species that fall under it, which is plainly false. But succession belongs to motion taken specifically — namely, to the continuous and temporal motion — and therefore does not belong to motion taken generically.

Objection I against the first part: Aristotle in *lib. Praedicam., c. de quantitate*, places motion among the species of successive quantity, for he says there that there are two species of successive quantity, motion and time; and he seems to repeat this in *5 Met., c. 13, T. 18*. Therefore according to Aristotle, succession pertains to the essence of motion. Reply: the Philosopher is to be expounded as speaking of motion not formally but materially taken — that is, of the form acquired through motion, which is continuous and successive.

Objection II: Motion is essentially either instantaneous or temporal and successive, for there is no middle ground between these; but motion is not essentially instantaneous — since a natural agent in operating does not move in an instant, and hence we have the celebrated maxim, "nature acts in time." Therefore it is essentially successive and temporal. Reply: motion in itself abstracts from both, just as animal abstracts from rational and irrational, and body from animate and inanimate. Nature does not operate in an instant because of the weakness and feebleness of its power. But a supernatural agent, because it possesses the greatest power and infinite potency, therefore operates in an instant.

Objection III: A measure must be of the same genus as what is measured, as stated in *10 Met., T. 4*; but time, which is the measure of motion, is successive, as is clear from its definition; therefore motion, which is measured by time, is continuous and successive. I grant the major and distinguish the minor: regarding continuous and successive motion, I grant; regarding motion in itself and taken generically, I deny. For time is the measure of continuous and successive motion, not of motion in itself and taken generically.

Article VI. How Many Kinds of Motion There Are.

There are many divisions of motion, of which some are called essential and others accidental. Among the essential ones, the first division is into instantaneous and successive motion, of which the Doctor makes mention in *2 d. 2, q. 9*. The second is into motion whose extremes are both positive, and into motion whose terminus from which is privation and terminus toward which is its habit — that is, a positive terminus — which Scotus touches upon in *4 d. 109, q. 1*. The third is into substantial motion, whose terminus is substance, and accidental motion, whose terminus is an accident — and this is indicated by the Doctor in *the commentary on 11 Met., sum. 4, c. 3*. The fourth is into natural, violent, and neutral — which Scotus indicates in *2 d. 2, q. 6, §. Ad propositum O.*, and *4 d. 48, q. 2*.

For discerning all essentially different motions, a certain and indubitable canon is available, drawn from Aristotle in *5 Phys.*, c. 4, T. 31, and Scotus in *1 d.* 2, q. 7, §. *Ad primum* T., and *d.* 13, q. vn., §. *Hic sunt A.*, and *3 d.* 14, §. *Ad 1. argum. ante E.*: motion is specified from the terminus toward which, such that there are as many essentially different motions as there are termini essentially distinct from one another. The reason is ready at hand, because motion formally is a relation, as has been said in *art. 4 of this quaest.*, and that relation is specified by its terminus, as I showed in *Log.*, l. 3, q. 6, *art. 7*. From this rule it can be conveniently seen which of the aforementioned divisions of motion are essential and which not. For indeed, if the termini of the primary division are of the same species — whether they come about in an instant or successively — the motions thereof will likewise be of the same species; thus if whiteness is produced in an instant or successively, it makes no difference — the "whitenings" of it are not essentially different, even if one is instantaneous and the other temporal. And Stagira clearly shows this in the passage just cited. The second division also does not appear to be essential, because it is drawn from the terminus in which (*terminus in quo*), which does not pertain to the essential character of motion, as will be plain in the next question. Intimating this, Aristotle enumerates motion and its species among the postpredicaments, as well as opposites and their members — contraries, privatives, contradictories, and relatives — in which motion occurs; and he touches on this not obscurely in *5 Phys.*, T. 7, where he presents a fourfold mode in which motion can occur. Therefore, whether motion presupposes a positive terminus from which, or a privative or negative one, this does not pertain to its essence and quiddity. The third, however, is essential, since the termini toward which of those motions are essentially different: for substance and accident are essentially different — as no one fails to see. The fourth is accidental, since it is drawn from the diverse relationship that the subject has to the form to be induced in it through motion: for if the subject inclines toward it, its motion is called natural; if it resists, the motion is called violent; and if it has neither inclination, it is called neutral. Therefore that division imports nothing pertaining to the essence of motion, and hence is not established as essential.

I add one essential tripartite division, according to the aforementioned canon, from *5 Phys.*, *sum.* 1, *cap.* 3, T. 10: into motion toward quantity — whose species are increase and decrease; toward quality — which is alteration, whose species are intension and remission; and toward place — which is local motion, whose species are listed in *7 Phys.*, T. 10: pushing, pulling, carrying, and rolling.

Furthermore, among the accidental divisions of motion, there are several besides those already listed: one into fast and slow motion, as stated in *4 Phys.*, T. 96; another into straight and reflex, as in *8 Phys.*, T. 64; a third into simple and mixed, as in *1 Caeli*, T. 7; a fourth into regular or uniform and irregular or difform, as in *2 Caeli*, T. 36. Concerning all of these we will speak in their proper places.

You will ask first: in what predicament does motion reside? Reply through distinction: motion materially taken is located in the predicament in which its terminus or form acquired through it is placed — so if its terminus is quantity, its motion is placed in the predicament of quantity; if it is quality, its motion is inscribed in the predicament of quality; and if it is "where" (*ubi*), it has its seat in the category of "where," as Scotus intimates in *Quol. 11, §. De quarto sub I.*, after Aristotle in *5 Phys., T. 10, 18*. But motion formally taken is located in the predicament of passion, because what relates a patient to its agent is passion, as Aristotle states in *5 Met., c. de relatione*, who establishes that the second genus of relatives is founded upon active and passive power, or upon action and passion; but the mobile, which is the patient, is related to the mover, which is the agent, through motion; therefore motion formally resides in the category of passion. So think Canon in *3 Phys., quaest. 1, art. 2*, and Parisiensis in the same place at *quaest. 2, fol. 48*, from whom Suarez in *disp. 49, Met., Sect. 2, 4* does not appear to deviate.

You will ask second: to how many predicaments per se does motion belong? Aristotle in *5 Phys., T. 10*, and Scotus in *1 dist. 3, quaest. 7, §. Ad argumenta pro 2. opinione infra R.* reply: to three only — quantity, quality, and "where." The reason is that motion per se and specifically taken — about which speech is instituted in the passage just noted — is continuous and successive, which can be effected only in those three categories; in the rest, change and not motion occurs, as the Doctor states concerning relation in *5 Met., quaest. 6, §. Ad aliud de relatione*. Hence two of our recent authors in *disp. 15, quaest. 6, art. 4*, placing motion per se in the category of substance, openly fight against Aristotle, Scotus cited, and *11 Met., summa 4, cap. 3*, and against the reason stated above.

Question II. On the Distinction and Unity of Motion.

Article I. How Motion Is Distinguished.

There is uncertainty about three things: the mover, the mobile, and the terminus toward which. Ockham in *2, quaest. 9* and his disciples acknowledge no distinction between motion and those three things just named. Others, whom the Coimbrans in *3 Phys., c. 2, quaest. 3, art. 2*, and Raconius in *disp. de motu, quaest. 3, propof. 2* follow, establish a formal distinction between motion and its terminus toward which. But the common opinion is that of Scotus in *2 dist. 1, quaest. 5, Secundum primam T.*, and *3 dist. 14, quaest. 1, §. Ad 1. ante F.*, and *4 dist. 43, quaest. 1, §. Aliter ponitur D.*, Canon in *3 Phys., quaest. 1, art. 1, propof. 1*, Tatar in the same place at *dub. 1*, Joan. de Magistris at *quaest. 2*, Parisiensis, Ruvio in *tract. 1 de motu, quaest. 4*, and Aureolus in *2 dist. 1, quaest. 3, art. 1*, who affirm that motion is really distinguished from the mover, the mobile, and the terminus toward which.

First Assertion: Motion really differs from the mover and the mobile. This is presupposed by the Doctor cited. The first part is proved: an efficient cause is

really distinct from its effect; for if it were identical with it, the same thing would be the cause of itself — which St. Augustine infers in *1 Trin.*, c. 3 as a great inconvenience and absurdity. But the mover is, as it were, the efficient cause of motion: for motion arises from the mover; therefore motion is really distinguished from the mover. Moreover, the mover can exist without motion, just as an agent can exist without action and a subject without an accident — and things that can exist and be separated from one another really differ, as Aristotle states in *7 Top.*, c. 8, 9, and Scotus in *2 d. 1, quaest. 4, §. Contra istam ante Alterum*. Motion is the relation of the mobile to the mover, as was established in the first question of this book, *art. 4*; and that relation is really distinguished from the foundation from which it proceeds, as I wrote in *Log.*, *lib. 3, quaest. 6, art. 4*. Therefore there exists a real distinction between the mover and motion. The first part of the second assertion is proved thus: what is in a subject is really distinguished from that very subject in which it is subjected, as is clear from accident and substance, from what is located and place, and universally from the contained and its container; but motion is in the mobile as in its subject, as is clear from its definition — for motion is defined as the act of the mobile as the mobile is, in *3 Phys.*, T. 9. Second: the mobile can exist without motion, for it is not necessary that the mobile always be actually moved; it can cease from motion and rest, just as anything rests in its own center; but between things of which one can exist while the other does not, a real distinction is clearly had, as stated in *7 Top.*, *cap. 1, loco 12*. Therefore since the mobile and motion are related in this way, it is evidently shown that they really differ from one another.

Second Assertion: Motion really differs from the terminus toward which. This is defended by the Doctor in the passages cited above, and is proved thus: first, what is prior to another by priority of time is really distinguished from what is temporally posterior; but motion temporally precedes the terminus toward which, since through motion that terminus is successively acquired — as is most especially the case in local motion; therefore they really differ from one another. Second: an absolute thing is really distinguished from a relation, especially one coming from without, since the absolute is a prerequisite and presupposed for the latter; but motion is a relation coming from without of the mobile to the mover, as is plain from what has been said; and the terminus toward which is most often something absolute — such as quantity, quality, or substance. Moreover, an accident is really distinguished from substance, as Stagira clearly shows in *7 Met.*, T. 4; but motion is an accident, since it inheres in the mobile, and the terminus toward which in substantial generation is substance. Finally, many things are attributed to motion that cannot belong to the terminus toward which: for motion is the way and progress toward the terminus, and is fast or slow, and so on — all of which cannot be accommodated to the terminus toward which; therefore these differ more than rationally and formally from one another.

Objection I: From *3 Phys., cap. 1, T. 4*: motion coincides with the things toward which it is; therefore according to Aristotle, motion is identical with the terminus toward which. Confirmed: a thing in becoming is not distinguished from the very thing in its completed being, just as what is imperfect does not differ from what is perfect — as is plain of man insofar as he is being generated and is generated; but motion is a thing in becoming, and the terminus toward which is the same thing in its completed being. And this seems to be what the Philosopher indicates in *5 Phys., 5*, saying that motion is not whiteness but a whitening. Reply: the Philosopher is to be expounded as speaking of motion materially, not formally taken. For he says there that motion is placed in the predicament in which its terminus is; and since there is per se motion only to three predicaments, it is placed in those three. To the confirmation: I grant the major and deny the minor. For motion is the way to making and completing the thing, not the very thing in becoming or in its completed being; for once the terminus has been acquired and the thing born, motion ceases, and with the thing persisting, motion vanishes, as stated in *1 de gener., T. 55*.

Objection II: Things that are really distinguished from one another are those of which one can be separated from the other, as I have urged more than once above; but motion cannot be separated from the mobile, just as an accident cannot be separated from its subject, and a relation cannot be separated from its terminus; therefore between motion and the mobile, and the terminus toward which, there falls no real distinction. Reply: the major does not hold in the case of relation, which is what motion is, because of the essential dependence that the relation itself imports toward its terminus, as I said in *Log.* in the passage recently mentioned. And moreover, because some — such as Tatar in *cit. dub. 2 in fine* — do not think it inconvenient that motion exist without a mobile, which Scotus seems to intimate in *4 dist. 12, quaest. 4, ante, §. Ad quaest. D.*, and in *Report., quaest. 5*.

You will ask: whether motion is distinguished from action and passion? Reply by distinguishing, with Scotus in *4 dist. 13, quaest. 1, §. Ad huius autem H.*, Canon in *3 Phys., quaest. 2, art. 2*, and Joan. de Magistris in the same place at *quaest. 3, scibili 3*: if the three things enumerated are taken materially, for the actual thing and form acquired in the patient, they are the same; but if they are taken formally, they are distinguished from one another. For action is the relation coming from without of the agent to the patient, or of the transmuting to the transmitted; passion is the relation of the patient to the agent, or of the transmitted to the transmuting; while motion is the relation of the mobile to the mover. And action and passion can exist without motion, such as the action and passion of creation. Likewise, when motion ceases, action and passion can still be elicited, as is plain in the case of heavy and light things in their own centers, in which they act and operate even though they rest in them. Moreover, God and the Blessed act without motion and change. Therefore action and passion are joined with motion principally in sublunary and transmutable things, while in the rest

they seem for the most part to abstract from it. Nor is it improbable that motion formally should not differ from passion, since they are of the same genus, as Joan. de Magistris cited intimates — from whom Suarez in the reply to the first point of the preceding article does not dissent.

Article II. From What the Unity of Motion Is Derived.

That the generic and specific unity of motion is to be drawn from both termini — the from which and the toward which — is maintained by Saxonia in *5 Phys.*, *quaest.* 6, Burley in the same place at *quaest.* 2, and Francis Sampson at *quaest.* 6. The common opinion, however, is that of Scotus in *1 dist.* 13, *quaest.* vn., §. *Ad argumenta principalia R.*, and *3 dist.* 14, *quaest.* 1, §. *Ad 1. Sub E.*, and *4 dist.* 43, *quaest.* 1, §. *Aliter ponitur D.*, Parisiensis, Tatar, Joan. de Magistris, and other interpreters of Aristotle in *5 Phys.*, *cap.* 4, *T.* 31, who affirm that the said unity of motion is to be sought from the terminus toward which. The numerical unity of motion is to be derived primarily from three things — namely, from the unity of the mobile, of time, and of the terminus toward which — as the common run of philosophers holds with Aristotle cited at *T.* 34.

Note first that unity is twofold: intrinsic and extrinsic. Intrinsic unity is that which follows upon the thing of which it is the unity; for each being is one, since unity is an attribute of being, as stated in *4 Met.*, *cap.* 2, *T.* 3. It is subdivided into transcendental and predicamental unity; the former belongs to every being, while the latter belongs only to those things that are placed in the categories, and is threefold: generic, specific, and numerical, as stated in *5 Met.*, *T.* 12. Extrinsic unity is that which is derived by reason of something one that is outside the essence of the thing — such as the objective unity of science, as stated in *1 Post.*, *T.* 43, and *3 de Anima*, *T.* 38. So too is the unity of motion with respect to its terminus toward which, which is extrinsic to motion itself, and which is threefold — generic, specific, and numerical — as Stagira indicates in *5 Phys.*, *T.* 31, through those three predicaments to which he wishes per se motion to extend, in accordance with a generic, specific, and numerical terminus toward which, placed in the said predicaments. It is about extrinsic unity that we now speak, because it is better known and more open to us, and it leads us to knowledge of intrinsic unity; and hence it has become established as a maxim among Philosophers that motions are specified by the termini toward which they tend.

Note second from Scotus in *4 dist.* 10, *quaest.* 3, §. *Ad 1. près finem, ad E.*, and *dist.* 43, *quaest.* 1, §. *Aliter ponitur Sub D.*, that numerical unity is twofold: one of identity, the other of continuity. The former follows upon the singular nature primarily from the individual difference (*haecceitas*); the latter arises from parts flowing into one whole. If the parts simultaneously persist and coexist, the unity of a permanent whole results; but if they flow away and one succeeds another, the unity of a successive whole arises — as happens in motion and in time, which is its measure. Moreover, many things intervene in motion, some of

which are necessary and some contingent. The mobile and the terminus toward which are necessary to motion, and are called by Averroes intrinsic to motion itself. The mover and time are extrinsic to it. The resistance of the mobile to the mover, the regularity and irregularity, and the uniformity and difformity of motion are accidental and contingent to it. For sometimes no resistance intervenes — as in the motion of the Heaven; sometimes the resistance of the mobile and of the medium exists — as in the motion of sublunary things; and sometimes no irregularity and difformity befalls the motion itself, as experience confirms.

First Assertion: The generic or specific unity of motion is sought from the terminus toward which. So hold Aristotle and Scotus cited at the beginning of this article, and Scotus in *1 Rep., dist. 13, quaest. vn.* This is urged thus: first, from what a thing is denominated, by that it is specified and takes its unity — as is plain from science, which is denominated, specified, and takes its unity from its object; but motion is denominated from the terminus toward which — as substantial generation is denominated from the generated substance, which is its terminus toward which; and similarly "heating" is denominated from heat, which is its terminus toward which; and "whitening" from whiteness, which likewise is its terminus toward which; therefore from the terminus toward which the generic or specific unity of motion is derived. Second: from some factor the generic or specific unity of motion must be drawn, as no one denies; but it is not taken from the mover, since several movers can concur in producing the same motion — as several pull one ship, several carry the same weight, and similar cases; nor from the medium, since the medium is per accidens related to the unity or diversity of motion; nor from the terminus from which, since the same terminus from which can be the starting point of diverse motions — such as cooling and heating; therefore it is rightly inferred that the said unity is derived from the terminus toward which. All the more so because motion is the way toward it.

Second Assertion: The numerical unity of motion is sought from the unity of the mobile, time, and the terminus toward which. So holds Aristotle in *5 Phys., T. 34*, and in *11 Met., sum. 4, cap. 3*, whom Scotus follows there, and indicates in *4 dist. 43, quaest. 2, §. Tertia opinio sub D.* This is proved: what is one by numerical unity of successive continuity requires the same subject, time, and terminus toward which; but one motion numerically is something one by the unity of successive continuity; therefore for the numerical unity of motion those three things just enumerated are required. The major is readily at hand, because such a unity is an accident that does not migrate from subject to subject; therefore it requires the same subject numerically, in which it inheres. Moreover, since it is a successive continuum, it requires the same time, since time is its measure, and measure and what is measured are of the same genus, as stated in *10 Met., T. 4*; and subsequently it requires the terminus toward which, from which it chiefly derives its numerical unity. The minor is conspicuous, since motion is an

accident, belongs to the genus of successive continuums, is measured by time, and is the way and progress toward the terminus toward which. I add: just as a specific motion derives its specific unity from the specific terminus toward which — as I showed in the first assertion — so a numerical motion derives its numerical unity from the numerical terminus toward which; as whitening derives its unity from whiteness, and this particular whitening from this particular whiteness; and blackening from blackness, and this particular blackening from this particular blackness — the former deriving specific unity from the specific terminus toward which, and the latter numerical unity from the numerical terminus toward which; therefore as many things are required for the numerical unity of motion as were enumerated above.

Objection I: If there is a motion from white to dusky, or to red, or to some other intermediate color, and again from black to the same color, there would be one and the same terminus toward which, even though there would be many motions; therefore from the terminus toward which the unity of motion is not derived. Reply: in the given hypothesis there would indeed be one and the same terminus toward which materially, yet there would be several formally — as I said in *Log., cap. 5, quaest. 1*, that if something is proved through diverse media with four premises and one conclusion, the conclusion will be one materially but twofold formally. Or it can be said that there would be two motions distinct numerically but one specifically, on account of the specific unity of the terminus toward which. Or that there would be two motions intrinsically but one extrinsically.

Objection II: Several specifically distinct motions can have the same terminus toward which — as straight and circular local motion tend toward the same "where," which is the terminus toward which; therefore the specific unity of motion is not taken from the unity of the terminus toward which. The antecedent is from Scotus in *1 d. 2, quaest. 7, §. Ad 1. T.*, and *3 d. 14, quaest. 1, §. Ad 1. ante F.*, and *4 d. 43, quaest. 1, §. Aliter ponitur D.* I deny the antecedent. To its proof I say that those motions differ not essentially but accidentally; for all local motions are of the same species, and if there is any difference among them, it is accidental. Hence just as curvature and straightness are accidental differences of a line, so circularity and perpendicularity are accidents of motion. And just as a white man and a black man are accidentally distinguished, so straight and circular motion differ accidentally — as Tatar attests in *5 Phys., q. 2, scibili 3*, from Scotus in the places cited.

You will press: Aristotle in *1 Caeli, cap. 3 & 4* proves — from the specific difference of straight and circular motion — that besides the four elements there is a fifth body, namely the heaven; therefore straight and circular motion differ from one another by an essential difference, otherwise the Philosopher would not prove that celestial body is essentially distinct from the elements. The reply must be that only an accidental distinction between those motions is

inferred, even though those bodies are essentially distinct from one another, because that argument is dialectical and *a posteriori*, not demonstrative and *a priori* — just as from an accident we arrive at knowledge of substance, and from an operation at knowledge of form; and in this way is Aristotle expounded at 5 *Phys.*, 33.

Objection III: From 8 *Phys.*, T. 49 & 82, the unity of the first mover — one, eternal, infinite, uncaused, and independent — is demonstrated through the unity of the motion of the primum mobile; therefore for the unity of motion, the unity of the mover is required. Reply: Aristotle there demonstrates the essential ordering of things to one first cause and first mover, who is God, the maker of all — on whom all created things depend in being and in operating — and does not intend that the unity of motion be derived from the unity of the mover; for the efficient cause, especially the universal one, does not specify or distinguish things, as is plain from the intellect, which is the universal cause of the sciences but by which the sciences are not specified, but rather by their objects, which are their particular causes. And all the more so because several causes can be causes of one and the same numerical effect, as is plain from things that are equivocally generated, born both by propagation and by putrefaction, as Scotus teaches in 1 *praalleg.* together with Augustine in *Epist. ad Deogratias*.

Objection IV: The progressive motion of an animal does not always require the same mobile; for with one of its parts at rest, another is moved — as when the feet are still, the head is moved; therefore for the numerical unity of motion the numerical unity of the mobile is not required. Reply: the motion of an animal is mixed, composed of the motion of pulling and pushing; but we speak of simple continuous motion, to which the unity of the subject or mobile is necessary. You will press: in 5 *Phys.*, T. 23, the motion of the first and last string of a lyre is continuous in a single time, and yet it has several mobiles — which are those several strings that are moved by a continuous simple motion; therefore the distinction just made between mixed and simple motion is invalid. The difficulty is met by saying that the Philosopher speaks of the motion of the player, which is truly continuous, and not of the motion of the strings, which is discontinuous in accordance with their plurality and diversity — as Aristotle and Scotus touch upon in 5 *Met.*, c. 6, 7, 8.

Objection V: If a dog falling from a high tower were to die in the middle of its fall, there would be one and the same numerically continuous motion, yet the mobile would not be the same, since a living and a dead dog are diverse mobile bodies; and again, a rod of which one part is dry and another part is green, if moved, would be moved by a single continuous motion even though there would be distinct mobiles according to the distinction of the parts; therefore the numerical unity of motion is not derived from the unity of the mobile. Reply: in the given hypothesis the mobile would be the same not in denomination but in

inherence, because the same mobile body, informed by the form of corporeity, persists — just as the same common accidents are possessed by a living and a dead body in which they inhere, as Scotus writes in *2 d. 2, q. 4, §. Ad 1. sub L.*, and *4 d. 12, q. 3*. You will press: Scotus in *5 Met., in com. c. 6, T. 9, in fine* writes that certain continuous things are diverse in subject according to species and form — as in a tree a dry branch alongside a green one, and in a man a withered hand joined to a living arm; therefore according to Scotus, for the numerical unity of motion the unity of the mobile is not required. Reply: in whatever way those things are related — whether living or dead — they have the same subject and the same mobile, because they are informed by a common and the same form of corporeity, even though their partial forms are distinct from one another. Therefore Scotus asserts nothing there that stands in our way, as is plain to anyone who meditates on that passage.

Article III. From What the Contrariety of Motion Is Taken.

Aristotle speaks at length and precisely of the contrariety of motions in *5 Phys., c. 5 & 6*, from *T. 46* to the last; and it is presupposed in the present context as certain that contrary motions exist — such as heating and cooling — and the question is whence their opposition and contrariety is taken. There are as many opinions of philosophers about the specification of the contrariety of motion as there were about its distinction and unity recounted above. For some of those cited think that motion derives its contrariety from both termini — the from which and the toward which; while others, among whom are Scotus in *2 d. 2, q. 7, §. Et ideo ad D. & E.* and his disciples and interpreters, affirm that the opposition and contrariety of motion is to be derived chiefly from the terminus toward which.

Note that Aristotle in the passage cited adduces five modes in which two motions can be opposed to and contrary with one another. The first is when the terminus from which of one is the terminus toward which of the other — as motion from illness and motion toward illness. The second is when the termini from which of both motions are contrary — as motion from health and from illness. The third is when the termini toward which of those same motions are contrary — as motion toward health and toward illness. The fourth is when the terminus from which of one is contrary to the terminus toward which of the other — as motion from whiteness and motion toward blackness. The fifth is when all the termini, both from which and toward which, are contrary — as motion from whiteness toward blackness, and motion from blackness toward whiteness. Among the aforementioned modes of contrariety of motion, two are properly contrary — namely the third and the fifth — as the Philosopher well concludes in the cited passage at *T. 48*: and indeed the third, because each motion respects termini toward which that are contrary to one another; and the fifth, because both motions have termini from which and toward which that are contrary, as is plain from the examples given.

Assertion: The contrariety of motion is derived chiefly from the termini toward which. So holds the Doctor in the passage cited above, after Aristotle in the passage just cited. This is urged thus: first, from what the unity and distinction of motion are taken, from the same its contrariety is also derived — because unity, diversity, opposition, and contrariety follow upon the specification of things; but motion takes its essential unity and distinction from the terminus toward which, as I proved in the two preceding articles; therefore from the same terminus toward which it derives its contrariety. Second: from what a thing takes its name and definition, from that it takes its distinction and contrariety, as Aristotle says in the passage just mentioned; but motion takes its name and definition from the terminus toward which, from the same passage; therefore it also takes its contrariety from the same terminus. Moreover, a relation is specified by its terminus, as I have urged more than once; but motion formally taken is a relation; therefore from the terminus toward which its opposition and contrariety arises.

Objection I: Aristotle in the passage just recounted approves the fifth mode of contrariety above the others, because the motions of that mode participate in contrary termini from which; and they are from contraries and toward contraries; therefore the contrariety of motions is derived from both termini from which and toward which. Reply through explanation and distinction of the antecedent: if we speak of an all-round and comprehensive contrariety of motion, I grant; but if of the most powerful and essential contrariety, I deny. For if the termini from which of two motions are contrary but their termini toward which are the same, the motions will not be contrary — as Aristotle states at *T.* 48, excluding the second mode from proper contrariety of motion.

Objection II: The same Philosopher at *cit. T.* 33 teaches that straight and circular motion differ specifically, even though they tend toward the same terminus toward which — which is "where"; therefore the contrariety of motion is drawn from both termini, the from which and the toward which. Reply by expounding the testimony of Aristotle through distinction: if straightness and circularity are taken in themselves and absolutely, I grant; but if in relation and in order to motion, I deny — just as is plain from a straight and a curved line, in which an accidental difference falls; but straightness and curvature precisely considered differ essentially; and similarly a white man and a black man differ accidentally, while whiteness and blackness differ essentially and specifically from one another.

You will ask: what contrariety exists between motion and rest? Reply with Aristotle in *cap.* 6 of the place cited: a privative contrariety. For rest is the privation of motion, just as blindness is the privation of sight, between which a privative opposition is established.

Article IV. How Motions Begin and Cease.

Taking the occasion offered by the inception and cessation of motions proposed in the title of this article for examination, it pleases me to investigate generally the inception and cessation of things, both permanent and successive, and, omitting what is trivial, to decide briefly and bring to light what St. Augustine shows to be difficult — for he labors and is agitated greatly in *13 De Civitate, cap. 11*, trying to satisfy a similar and related difficulty.

Note first that the inception of a thing means nothing other than the beginning of its duration, and its cessation means the end and terminus of that same duration — so that the inception and cessation of a thing are two extremes and termini within which its duration is enclosed. Now since, from what was said in *the preceding book, quaest. 1, art. 5, not. 2*, there are four principal measures by which things endure and through which we arrive at knowledge of them, therefore all the modes in which instantaneous and temporal, permanent and successive, divisible and indivisible things begin and cease must be stated — and once these are known and clear, it will not be difficult or arduous to attain knowledge of them, as Tatar intimates in *8 Phys., q. 3, dubit. 2*.

Note second from Scotus in *Quol. 12, art. 3, ante §. Ad 1. arg. M.* that there are two modes common to things for beginning and two equally for ceasing. The first mode of beginning is positive and intrinsic, by which a thing begins through its first instant of being, in which it is true to say "the thing is now, and immediately before was not"; and it is called positive and intrinsic because in that moment it posits the thing as beginning and as possessing its own intrinsic existence. The second is negative and extrinsic, by which a thing begins through the last instant of its non-being, by which it is affirmed that "the thing is not now, and immediately after will be." It is called negative because it denies that the thing is in that instant, and extrinsic because it is outside that very instant. The first mode of ceasing is positive and intrinsic, by which a thing ceases through the last of its being, by which it is affirmed that "the thing is now, and immediately after will not be"; the second is negative and extrinsic, by which a thing ceases through its first non-being, by which it is said that "the thing is not now, and immediately before was."

First Assertion: Successive things — such as motion and time — begin through their first non-being and cease through their last non-being. This is defended by Scotus in *2 d. 2, quaest. 9, §. Ad argumenta sub N.*, whom Gadius in *Quol. 12*, Joan. de Magistris in *8 Phys., quaest. 6, scilili 1*, Parisiensis at *quaest. 2, fol. 87*, Tatar cited, and others commonly follow. This is proved thus: first, those that have continuous prior and posterior parts that flow on without end begin and cease extrinsically — that is, through their first non-being and through their last non-being; but motion and time have prior and posterior parts in perennial and continuous flux; therefore they begin and cease extrinsically, through their first non-being and through their last non-being. The major is established because they are successive, partible, and divisible into parts infinitely partible and

divisible, for which it is incompatible to be measured by an indivisible and insectile measure, such as instants and moments. The minor is clear from the definitions of motion and time given above. Second: a measure and what is measured must be proportioned, since they are of the same genus, as stated in *10 Met.*, *T. 4*; but time and motion are continuous and successive; therefore their inception and cessation must be measured by a continuous successive measure, which is expressed through the first and last of their non-being, roughly in the way I explained in the second note.

The inception and cessation of rest are governed by the same measure. The reason is that rest and motion are opposites, and opposites are subject to the same treatment, as stated in *2 Priorum*, *cap. 1, sect. 3*, and *1 Top.*, *cap. 14*, cited by Scotus in *1 Met.*, *in com.*, *cap. 1*. Thus rest begins and ceases as does the motion opposed to it, as Scotus intimates in the passage just cited at *O.*, and in *2 d. 2, quaestio 4, §. Concedo. C.*

You will press: from *6 Phys.*, *cap. 3, T. 31*, the Philosopher seems to wish that rest begins and ceases in an instant; but what begins and ceases in a moment begins and ceases intrinsically, through its first and its last being; therefore the inception and cessation of rest are not to be measured as those of motion, which begins and ceases extrinsically. The reply must be that the Philosopher indeed raises as a question whether anything is moved and rests in a moment, but at the end of that text he concludes and establishes that motion and rest are in time; and therefore that the mobile is moved and rests in time, but in no way in an instant.

Second Assertion: Indivisibles — instants of time, instances of having-changed in motion, generation, illumination, and the like — begin through their first being and cease through their last being. So Scotus in *Quol. 12, art. 3, L.*, and *2 d. 2, q. 6, §. Ad 1. arg. H.* This is proved: such as the being of a thing is, such is its measure — since through the measure we arrive at knowledge of the being, and the measure is proportioned to it; but momentary things are indivisible and impartible; therefore they are measured by an indivisible and impartible measure, such as an instant; and things that are measured by this measure begin through their first being and cease through their last being; therefore the things named above begin and cease in this way. Moreover, whatever begins and ceases, begins and ceases either intrinsically or extrinsically, as I made plain in the second note; but instantaneous and indivisible things do not begin and cease extrinsically, otherwise they would have been successive and partible; therefore intrinsically — which is to begin through the first and to cease through the last of their being.

Third Assertion: Permanent things that have their whole being simultaneously and perfectly begin and cease intrinsically; while those that acquire being successively begin and cease extrinsically. So holds the Doctor in *Quol. 12, §. De tertio L.* The first part is evident: such is the measure as is the entity measured

through it, as stated in *10 Met.*, *T. 4*; but the inception of a permanent thing having its whole being simultaneously endures in the instant, which begins intrinsically; therefore similarly its being begins and ceases intrinsically. The second part is plain: things that endure through time begin and cease extrinsically, as I explained above; and things that come about successively are measured by time, which is the measure of successive things; therefore they begin and cease extrinsically.

You will say: permanent things are measured by the aeon, which is a measure distinct from time; therefore their inception and cessation do not occur through the extrinsic but through the intrinsic. The difficulty is met by saying that this holds of permanent things that have their whole being simultaneously, but not of permanent things whose being is successively acquired.

You will press: from *8 Phys.*, *T. 69*, the corruption of a substantial form ceases extrinsically — that is, through its first non-being — and yet it is a permanent being; therefore the stated principle is not universally true. I say this is not to be sought on the side of the substance itself and its corruption, but on the side of the mover and the mobile, whose action and passion occur successively and in time. And especially because an agent cannot at one and the same instant both corrupt the pre-existing form and introduce a new one into the same subject; and immediate instants do not exist, as the Doctor rightly pursues in the passage cited above, and Lychetus and Gadius demonstrate at length in the same place.

Question III. On the Mobile.

Article I. Whether an Indivisible Can Be Moved Locally.

The prior opinion, held by Averroes in *6 Phys.*, *com. 86*, Janduno at *quaest. 13*, the Coimbrans in the same place at *cap. 10, q. on., art. 2*, and Ruvio, denies that an indivisible can be moved per se. The latter opinion is that of Scotus in *2 d. 2, quaest. 9, §. Ad 3. principale*, Mayr in the same place at *quaest. 12*, Ballesteros at *quaest. 4, art. 2*, Tatar in *6 Phys.*, *quaest. ult., dub. 2*, Parisiensis at *quaest. 3, fol. 75*, Joan. de Magistris, and others in that place, who affirm that an indivisible can be moved locally per se.

Note first that the controversy in the present context is not about a substantial indivisible — such as an Angel or a rational soul, for these are not questioned here as capable of being moved per se — but about an indivisible of quantity, such as a point in a line, an instant in time, and a "having-changed" in motion; and not insofar as such an indivisible is joined to a continuum — for in that case it is moved by the motion of the continuum — but insofar as it is separated and detached from it; and in this way it is investigated whether an indivisible separated from a continuum can be moved by local motion, or by some other motion of alteration, generation, or corruption.

Note second that something can be moved in three ways: first, *per se*, because it is undivided from itself and divided from everything else and is moved — as man; second, through a part — in this way a whole is said to be moved because some part of it is moved, as a man is moved because his hand is moved; third, *per accidens* — in this way, with us being moved, all things that are in us are moved, and so with a vessel being moved, all things that are in the vessel are moved. Moreover, it should be recalled from what was said that the succession and divisibility of motion can be derived either from the divisibility of the mobile, which is continuous and divisible into prior and posterior parts, or from the divisibility of the space to be traversed, which is likewise continuous and has parts after parts divisible to infinity.

Assertion: If an indivisible of quantity were to be separated from a continuum, it could be moved locally *per se*. So holds the Doctor cited. This is proved thus: first, what is moved *per accidens* can be moved *per se* — as is clear from water, which is moved *per accidens* by the motion of a vessel but which would be moved *per se* if separated from the vessel, for it would then be carried to a low place and seek its own center. And this can be illustrated even from a part, which is moved *per accidens* by the motion of the whole but which could move *per se* if removed from it, as is plain from the second note. But an indivisible of quantity is moved *per accidens* by the motion of the continuum; therefore if separated from it, it would be moved *per se*. Nor does it help to say that there is a disparity because to be moved *per se* is to be moved by a motion existing in the thing itself, while to be moved *per accidens* is to be moved by a motion existing in another subject — since in a separated indivisible there would be motion, given that it is a physical being and every physical being is mobile, for mobility is its attribute. And all the more so: if a perfectly spherical body were moved on a flat surface, it would touch that surface at a point — which Aristotle thinks possible in *de Anima*, T. 13, cap. 1 — and that point would be moved locally just as the body would be moved locally; and indeed, if the body were separated from it, the point would certainly be moved, both because it is not immobile — otherwise it would be God — and because the separation of one from another indicates motion. If therefore an indivisible can be separated from a continuum — as the adversaries admit from the hypothesis given — it can certainly be moved *per se*. Again: when a circle is moved, a point existing in it acquires a new and different relation of presentness; therefore it is moved, since it is always in a different state; and if the circle were destroyed while the point persisted, such a point could be transferred to another newly produced circle, and therefore the point itself would be moved. Second: an Angel can exist in a point, as Scotus writes in 2 d. 2, quaest. 6, §. *Ad propositum K.*, whom many theologians follow, among whom are Ockham in *Quol.* 1, quaest. 4, Gabriel in 2 d. 2, q. 2, and the Coimbrans in *cit. art.* 3; and in the given hypothesis, the Angel would move the point and could transfer that very point from one place to another; therefore an indivisible such as a point can be

moved locally per se. The Coimbrans, once the case is admitted of an Angel moving a point, object that it does so not by a continuous but by a discrete and as it were leaping motion — just as a point moved in a globe is moved not continuously but discretely. Against this: an Angel cannot traverse a continuous space except by continuous motion; for it is necessary that it traverse the prior parts before running through the posterior ones, and the middle before the extreme; therefore not by discrete but by continuous motion would it move a point from one place to another. The antecedent is ready at hand: motion is called continuous if the space in which it occurs is continuous, but the space is continuous as the named authors themselves admit; therefore the motion is also continuous; even if it proceeds by leaping, because no passage is made from one extreme to the other without traversing the middle. Again: the rational soul, which is indivisible, moves the body it informs by continuous motion, and if it existed in a point of that body, it could still move it continuously through the parts of the same body; therefore an Angel, possessing greater power, can do the same. Third: an indivisible of quantity has its own gravity or levity, even if slight; but heavy and light things are moved locally, and if extracted from their proper places with every obstacle removed, they are borne to them by their own nature; and no incompatibility is seen. If therefore an indivisible were removed from the continuum, there is no contradiction in its being moved locally.

You will say with Raconius in *disp. de motu, art. 3, quaest. 5* that the aforesaid gravity or levity of the indivisible does not suffice for a point to tend downward or upward, because of its smallness and lack of extension — for motion requires extension of the mobile, of which a point is devoid. Against this: every heavy thing tends downward and every light thing upward, whether great or small — just as every man is risible, whether large or small; therefore an indivisible can be moved, even though it participates in only slight levity or gravity. To say that extension and magnitude are required on the side of the mobile is to beg the question, which I have already refuted and destroyed above.

Objection I: Aristotle in 6 *Phys.*, c. 3, 4, T. 33 expressly denies that an indivisible can be moved per se; and he repeats the same in 8 *Phys.*, cap. 5, T. 40. Therefore our assertion conflicts with Peripatetic doctrine. Reply: the Philosopher is to be expounded as speaking of continuous motion by reason of the mobile — that is, of the indivisible. For an indivisible, as indivisible, cannot be moved divisibly and continuously. And this is also affirmed of an Angel and the other indivisible substances — and not of continuous motion by reason of the space to be traversed. For since the space to be traversed is divisible and continuous, consequently on its part motion is established as divisible and continuous, even if the mobile is impartible and insectile. You will press: the same Aristotle accumulates many arguments to urge that an indivisible cannot be moved per se; but it is plain that an indivisible cannot be moved divisibly, since it is devoid of parts; therefore his meaning is to show that such an indivisible cannot be moved per se either from its own side or from the side of the space. I say that

this holds of an indivisible joined to a continuum, but not of an indivisible separated from it — which is the subject of contention — and perhaps Stagira did not know that an indivisible can be separated from a continuum; and so he speaks absolutely, while we speak conditionally and introduce the said distinction to dissolve the opposing argument. Or say with Scotus cited that his arguments prove nothing other than that the continuity of the motion of an indivisible is not derived from the indivisible itself — as is most clearly evident from his fourth argument, which runs thus: the continuity of time and of the mobile are ordered, since the continuity of time is from the continuity of motion and the continuity of motion from the continuity of the mobile; but the indivisible is not continuous; therefore from it, according to Aristotle, continuity is not derived — but from the divisible space and the continuous mobile; and so our distinction stated above holds in the sense of the Philosopher.

Objection II: Everything that is locally moved is partly in the terminus from which and partly in the terminus toward which; but an indivisible cannot be partly in the terminus from which and partly in the terminus toward which; therefore an indivisible cannot be moved locally per se. The major is supported by the authority of Aristotle and is shown: if the mobile were totally in the terminus from which, it would not be being moved but would be going to be moved; if totally in the terminus toward which, it would not be being moved but would already have been moved; and in both termini simultaneously it cannot be, since it cannot be in two places at once, nor in neither of the termini since it moves from one to the other. The minor is established because an indivisible lacks parts. Reply: the argument is true and valid of a divisible and continuous mobile, which — both from its own side and from the side of space — has divisibility and continuity; but it is futile and empty in the case of an indivisible mobile, which is not divisibly and continuously moved by reason of itself but by reason of divisible space. Or say that it is not necessary for the mobile to consist of parts in order to be moved continuously, but it suffices that with respect to space it be partly in act and partly in potency — which would belong to an indivisible if it were to traverse some space, for it would first pervade a smaller, then a greater, and then the whole.

Objection III: What is locally moved first traverses a smaller space than a greater, and a lesser than an equal, and an equal than the whole; but an indivisible cannot be greater or smaller — for this presupposes the continuity and divisibility of the mobile, which cannot be fitting to what is insectile; therefore an indivisible is incapable of motion per se. I grant the major and distinguish the minor: by reason of itself, I grant; by reason of the space, I deny. For an indivisible is moved continuously by reason of continuous and divisible space.

Article II. Whether Anything Can Be Moved Locally in an Instant.

On this very difficult and arduous article there exist two opinions opposed to one another. One is attributed to Thomas in *4 d. 44, q. 2, art. 3*, and *6 Phys.* cited by Tolet in the same place at *quaest. 3, cap. 3, in tex. 32*, Richard in *1 d. 37, art. 3, quaest. 3*, Raconius in *disp. de motu, sect. 3, q. 2, propof. 2*, and others, who think that for a body to be moved locally in an instant involves incompatibility. The other is that of the Subtle Doctor in *3 d. 2, q. 3, §. quantum ad 2. C.*, and *d. 4, q. vn., §. potest dici, Sub B.*, and *4 d. 43, q. 5, §. de secundo C.*, Joan. de Magistris in *6 Phys., quaest. 2*, Parisiensis in the same place at *fol. 75*, the Coimbrans in *3 Phys., cap. 2, q. 2, art. 3*, Ruvio in *6 of the same work, cap. 3, q. vn., near the end*, and many others, who affirm that local motion can by divine power be effected in an instant.

Note that local motion being accomplished in an instant can be taken in two ways: in one way, with the medium traversed — that is, with the interval that lies between the terminus from which and the terminus toward which traversed; in this way motion cannot be accomplished in an instant, as is plain from Aristotle in *6 Phys., cap. 3*, and *5 Met., c. 13, T. 18*, and Scotus in *2 d. 2, q. 9, sub N.* — for that space which intervenes between the terminus from which and the terminus toward which is continuous and divisible, and consequently can only be traversed successively and in time. In the other way, without the medium being traversed, so that motion is taken solely as the acquisition of a form in the terminus toward which — and the difficulty is whether anything can in an instant be brought or produced from the terminus from which in the terminus toward which. In this sense the authors of the second opinion affirm that local motion can be accomplished in an instant, against which the patrons of the first opinion resist.

Assertion: By supernatural power, local motion can be accomplished in an instant. So holds the Doctor in the passages cited above. This is urged thus: first, from *8 Phys., sum. 4, T. 78*: if there were an infinite power in a magnitude, it would move in no-time — which is the same as in an instant; therefore local motion in an instant is not impossible. Second: the reason why local motion and the form to be acquired through it cannot be accomplished in an instant is either the resistance of the contrary, or the finite power of the mover, or something else enumerated by the Seraphic Doctor in *1 d. 37, art. 2, quaest. 3*; but nothing resists supernatural power — for it is the omnipotence of God and His will, to which nothing can resist, as stated in *Romans IX*. Therefore by divine power local motion can be accomplished in an instant, or the form acquired through motion. The major is ready at hand, for where there is no resistance of the contrary, motion is accomplished in an instant — such as illumination and generation; and a stronger power acts more quickly than a weak one; therefore an infinite power, such as the divine, moves and acts in an instant, as is plain in the creation of things: *Ecclesiasticus XVIII*, "He who lives forever created all things simultaneously." And in the resurrection of the dead: *1 Cor. XV*, "In a moment, in the twinkling of an eye." The same teaches St. Augustine in *11 contra Faustum, cap. 7*, and *serm. 28 de verbis Apostoli*, and in *Ench., cap. 9*; and Bernard

writes the same in *serm. 4 in festo Sanctorum Omnium*. Again: from the most pure blood of the Blessed Virgin, in the instant in which the Virgin spoke those words in *Luke I*, "Behold the handmaid of the Lord; be it done to me according to your word," the Incarnation of the divine Word was accomplished. Finally: that one body by divine power can simultaneously exist in two adequate, discontinuous, and distant places, I proved in *1, 6, q. 2, art. 4*; but such existence of said bodies is not without local motion; therefore local motion can be accomplished in an instant.

Objection I: From *3 Phys., T. 1*: motion belongs to the genus of continua; but what is continuous is divisible, and its motion is successive; therefore local motion cannot be instantaneous. Reply: Aristotle there speaks not of the proper but of the improper and broadly taken genus — just as Goliath is said to be of the race of giants, and Bonaventure of the race of Italians. Hence he appends the word "seems," which is not the voice of one firmly asserting but rather of one questioning.

Objection II: Local motion requires some distance and space that intervenes between the terminus from which and the terminus toward which; but such traversable space is divisible, in which the mobile is moved divisibly, continuously, and successively; therefore instantaneous local motion is incompatible. Reply through distinction of the minor: if the motion takes place with the medium traversed, I grant; but if it is accomplished without the traversal of the medium, I deny — as I made plain above.

Objection III: A mobile that is moved locally is either wholly in the terminus from which or wholly in the terminus toward which; but in the terminus from which it begins to move, and in the terminus toward which it ceases to move; therefore some delay and succession intervenes for the mobile to move from the terminus from which and seek the terminus toward which, and so local motion is always successive. Reply: the mobile is moved wholly in the terminus from which and in one instant — with no medium traversed — is in the terminus toward which. The reason is that in *6 Phys., T. 28*, in instantaneous things the "coming to be" is not distinguished from the "having come to be," nor is the "being changed" distinguished from the "having been changed" — even though it is said to be prior by nature that it is moved in the terminus from which and posterior by nature that it is in the terminus toward which.

Article III. Whether What Is Moved Is Moved by Another.

Aristotle in *7 Phys., T. 1 & 2*, and *8 of the same work, T. 29*, and *12 Met., c. 8, T. 43* puts forth this proposition: whatever is moved is moved by another. Whether this is universally true or not, his interpreters contend. For Thomas in his commentary and many others receive the stated proposition as universally true. But Scotus in *9 Met., q. 14*, Antonius Andreas in the same place at *q. 1*, and not a

few moderns think that it is indefinite — that is, true in some cases and false in others.

Note that for something to be moved can happen in two ways: either from an extrinsic principle — as a carriage by a coachman, and the heaven by an Intelligence — or from an intrinsic principle — as a man by his own power. Again, something can both move and be moved — as the soul moves and is moved by itself. Moreover, something can be moved and not move — as a stone thrown by the one throwing it. And again, something can be a mover and not be moved — thus God, remaining unmoved, gives all things to be moved. Furthermore, something can be moved toward first act — that is, toward essential being — and in this way nothing can move itself toward first act, since nothing can produce itself; or toward second act — and in this way something can well be moved toward second act, since after it has received the being it obtained through production from another, it has the power of operating; and in this way, after man has been created, he has the power of understanding, willing, and exercising other operations, which are called second acts.

Assertion: It is not universally true that whatever is moved is moved by another. So Scotus in the passage cited above and in *2 d. 2, q. 10*. This is proved thus: first, from *8 Phys., T. 29, 30*, where it is stated that animals are moved by themselves — that is, by a form and power intrinsic to them. Second: water heated from itself and from its own form reduces itself to its native coldness. And likewise man moves himself by spontaneous motion and freely determines himself to act. Add what we will assert in the next article — that heavy and light things move themselves. Thus the Philosopher's statement seems to be valid only for those things that are moved by a subordinated motion — as fire is moved by the heaven, the heaven by an Angel, and the Angel by God. And so in that passage the Philosopher himself concludes that there is one first mover who is not moved by another — as a stick by a hand and a hand by the heart.

Objection I: From *7 Phys., T. 2*: what is moved such that if any of its parts rests, the whole itself rests, is not moved by itself but by another, because its motion depends on the motion of that part; for it is moved with the motion of the part and rests with its rest — and every thing that is moved is of this sort; therefore everything that is moved is moved by another. I grant the major and distinguish the minor with Scotus in *9 Met., q. 14, §. de aliis*, after Simplicius in the present context: regarding inorganic motion, I deny; regarding the organic and progressive motion of an animal, I grant — as is plain from the heart, which moves the remaining parts of the body of the animal, but with the heart at rest the remaining members rest. This reply is indicated by Stagira in *8 Phys., T. 29*, and in *the book on the common motion, cap. 1*, adduced and expounded by Ferchius in *1, 2 vestig. 3, num. 33, 34*.

Objection II: The same thing cannot be simultaneously in potency and in act; for it involves incompatibility for the same thing to be simultaneously moved in

act and not moved but to be in potency to motion; but if what is moved were not moved by another, the same would be simultaneously in act and in potency; therefore the stated saying is universally true — everything that is moved is moved by another. I distinguish the major with Scotus in *2 d. 25, q. vn., §. Ad primam T.*: the same thing cannot simultaneously be in objective potency and in entitative act, I grant; the same thing cannot be in formal and subjective potency and in virtual act, I deny. And this is illustrated in a non-univocal but equivocal agent, which is in potency to a form of another character from that which it participates — as the Doctor explains at length in *9 Met., q. 14, §. contra responsionem istam*, and *§. quod additur*.

Objection III: From *1 de Gener., T. 52, sum. 4, cap. 4*, and *1 de Anima, T. 52*, and *2 of the same work, sum. 3, cap. 2, T. 54*: the same thing cannot act and be acted upon simultaneously; but if something moved itself, the same would both act — because it would move — and be acted upon — because it would be moved by itself; therefore, etc. I distinguish the major: in the same way and by the same character, I grant; in a different way and by a different character, I deny. And this is plain from the intellect, which produces the act of intellection — by reason of which it is called active — and receives that same intellection — through which it is called passive.

You will ask: whether the mover and the moved are always together? Reply: sometimes they are together in simultaneity of supposit and of power — as the orb of the Moon with the sphere of the Sun; and sometimes in simultaneity of power only — as the Sun by its power reaches these inferior and sublunary things.

Article IV. By What Are Heavy and Light Things Moved.

Richard in *2 d. 14, art. 2, quaest. 4*, and John of Maistre in *8 Phys., quaest. 4, dub. 1*, report many and divergent opinions on this matter, among which I note and present two more celebrated ones. The prior is that of Thomas in *1 part., quaest. 18, art. 1*, Cajetan in the same place, the Coimbrans in *disp. 18, Phys., quaest. 2, §. 2*, and others, who affirm that heavy and light things are moved per se by the generator and per accidens by the one removing the obstacle. The latter is defended by Scotus in *9 Met., quaest. 14*, Antonius Andreas in the same place at *quaest. 1 & 2*, and in *dist. 2, quaest. 10*, and *dist. 25, quaest. vn., §. Ad primam sub C.*, Mayr in *dist. 14, quaest. 6*, and the other Scotists, who teach that heavy and light things are moved by themselves.

Note that to be moved by oneself is the same as to have an intrinsic active principle of one's motion — just as to be moved by another means nothing other than to be moved by an extrinsic principle. An example of the first: man is moved by himself — that is, by a power existing in him — and in *1 de Anima, T. 67*, from Plato it is said that "the soul is a number moving itself." An example of the second: a carriage is moved by another — namely by the coachman. Now

since experience makes it certain that heavy things are moved downward and light things upward, it is investigated in the present context whether this kind of motion is effected by a principle and power intrinsic or extrinsic to them; and the dispute is not about a remote and mediate principle, but about the proximate and immediate one from which the actual motion of heavy and light things proceeds.

Assertion: Heavy and light things are moved by themselves. So Scotus in the passage cited above, and before him the divine Plato as reported by Bonetus in *5 Phys.*, *cap.* 3. This is proved thus: first, from *8 Phys.*, *sum.* 2, *cap.* 2, *T.* 32: as the knower is related to contemplation and fire to combustion, so are heavy and light things related to their natural motions; but the knower has an internal and active principle of contemplation, and fire of combustion; therefore heavy and light things likewise, according to Aristotle, have an intrinsic principle of their natural motions. Moreover, it is subjoined there that if a light thing is impeded from tending upward and then the obstacle is removed, it acts and seeks the upper place; and in *4 Caeli*, *cap.* 1, *T.* 2, it is written that heavy and light things have certain impulses of motion; and at *T.* 25, *sum.* 2, it is added that heavy and light things have intrinsic principles of their motions to their proper places, while what is healable and what is capable of growth have extrinsic principles. It is plainly the case that the text speaks of active and not passive principles, since in respect of the latter there is no difference, but only in respect of the former. Again: in *4 Phys.*, *sum.* 2, *cap.* 5, *T.* 85: the dense and the rare, as heavy and light, have an active principle of motion; but as hard and soft, they have a passive principle of motion.

You will say: in *2 de Gener.*, *T.* 8, heavy and light things are not numbered among the active principles; therefore either they lack activity, or Aristotle admits contradictions in his writings. I say there is no contradiction in the writings of the Philosopher: for in *8 Phys.* cited he says that heavy and light things act with respect to their proper places and centers; but in the second book *de Generatione* he denies that they are active and productive of things similar to themselves in species — as a man produces a man and fire produces fire — as Scotus explains at length and learnedly in the passage cited. Second: an effect in act has its cause in act, as stated in *2 Phys.*, *T.* 37, and *5 Met.*, *c.* 1, *T.* 3; the reason being that nothing can be caused in act unless the cause is actually causing it — that is, actually exercising its causality; but since heavy and light things are actually moved, their effect is in act — that is, their actual motion — while the generator does not exist, either being absent or already having perished; therefore heavy and light things are not moved by the generator but by themselves. The Coimbrans in *5 Phys.*, *cap.* 4, *quaest.* *vn.*, *art.* 4 reply that even if the generator does not exist, its moving power exists — which it communicated to the generated thing; and for this reason it is chiefly said to be moved by the generator when the effect of the generator goes forth into motion. Against this: the power by which the generated thing is moved is distinct from the power of the generator

— for just as the nature of this is at least numerically distinct from the nature of that, so the power of this is distinct from the power of that; therefore the generated thing is moved by itself — that is, by the power existing in it itself. For what is investigated is not by what it could be moved, but by what it is actually moved; but it is moved by the power intrinsic to it; therefore it is moved by itself. Moreover, a certain and determinate sphere of an agent and mover is established; but in whatever distance or proximity the generator may be, the generated thing is moved by the power existing in it itself. Furthermore, if inanimate things were moved by the generator because the generator instilled a power in them, plainly even animate things would be moved by the generator, since they equally received from it the power of moving themselves — just as inanimate things; but the adversaries deny this of the latter; therefore they should deny it of the former as well, since the same reasoning applies to both alike. Second: if a small light thing is tied to a large heavy one, the latter drags the former; but the motion of the heavy thing is the cause of the descent of the light thing attached to it, through nothing other than the principle existing in that heavy thing and intrinsic to it. And all the more so — noting Scotus in *1 dist. 2, quaest. 5, ad fiem, §. Contra 1, art.* — if a heavy thing is held upward and overcomes the power of the one impeding it from going downward, once the obstacle is removed it descends downward; but that motion and descent is not effected by the generator — since it is supposed to be absent or extinct — nor by the one impeding, except per accidens, nor by any other extrinsic thing, as is plain; therefore it is effected by itself. Moreover, a heavier thing descends more quickly than a lighter one, which derives from nothing other than the intrinsic principle. These and other arguments are of such great weight that Suarez in *disp. 28, Met., Sect. 7, num. 22*, and Ferrariensis in *4 contra Gentes, cap. ult.*, and others cited by the Coimbrans in the passage cited, admit that heavy and light things are moved by gravity and levity as by an active principle — even if an instrumental one. But if these authors concede this of the instrumental principle, they ought likewise to admit it of the principal one, since the power of the instrument draws its strength from the principal; and Thomas himself confesses this in *1, 2, question 6, art. 6*, and in other places cited by the Coimbrans — especially in *2 dist. 18, quaest. 1, art. 2*, where in explicit words it is read: "Not all motions are called natural in the same way, but some on account of an active principle existing within — such as the local motion of heavy and light things."

Objection I: Aristotle in *8 Phys., cap. 2, T. 33, sum. 2* expressly says that heavy and light things are moved by the generator and not by themselves; and he asserts this especially because of the saying he advanced in *7 Phys., T. 2*: "everything that is moved is moved by another." That this was indeed his meaning, Bonetus in *5 Phys., cap. 3* abundantly and learnedly declares and proves, asserting the opinion of Plato as diverging from that of Aristotle. Reply: the Philosopher is to be expounded as speaking of the remote and not the proximate principle — about which the whole dispute is now. This distinction is deduced from *8 Phys., T. 32*:

to be in potency can occur in two ways — to first act or essential being, and to second act or accidental being — as I made plain in the preceding article, where I also explained the stated saying of Aristotle.

Objection II: What moves to first act likewise moves to second act; for what gives being equally gives what follows upon being — and as the jurists say: "who gives the principal gives the accessory." But the generator confers first act — namely, being heavy or light; therefore it also confers second act — namely, operating, which is to be moved; and hence their motion is effected by the generator. I distinguish the major: proximately and immediately, I deny; remotely and mediately, I grant. For even though the generator has conferred on heavy and light things their being and the power of moving, nevertheless it is not the proximate and immediate principle of their motion. For it suffices to have given them the principle of moving, and with that obtained, they subsequently move themselves to their proper place and center — once the obstacle is removed, even if the generator has been destroyed or is far distant.

Objection III: If heavy and light things were moved by themselves, there would be no difference between the motion of animate and inanimate things — since both animate and inanimate things would be moved by themselves; but this conflicts with truth and the authority of Aristotle in *8 Phys.*, *T. 29*, where it is read that animate things move themselves, while inanimate heavy and light things do not do so in the same way. I deny the consequence of the major, with Scotus in *4 dist. 49, quaest. 14, §. Respondeo hic*: for animate things move themselves with prior cognition, and if moved by progressive motion they can stop themselves when an object apprehended by them presents itself — as is plain from brute animals — and can also be moved in their own place and center, which does not belong to heavy and light inanimate things.

Article V. By What Are Projectiles Moved.

I find philosophers both ancient and modern who disagree in investigating and identifying the cause of the motion of projectiles. For some, among whom is Plato as Aristotle reports in *8 Phys.*, *T. 82*, hold that the motion of projectiles is produced by antiperistasis. Others — such as Mayr in *2 d. 14, q. 7*, Thomas in *3 Caeli, ad T. 28*, and Camerarius — assert that the cause of the motion of projectiles is to be sought in the medium or surrounding air, supported by Aristotle in the passage cited. Still others — such as John of Maistre in *8 Phys.*, *q. vlt., dub. 2*, Tatar in the same place at *scibili 4*, the Coimbrans in *cap. 2, quaest. 1, art. 8*, Tolet at *tex. 86*, Raconius in *disp. de motu, num. 2, art. 1*, and the greater part of recent authors — teach that projectiles are moved by a power impressed upon the projectiles themselves.

Note that in the motion of projectiles many things intervene: the projector, the projectile, and the medium, and the impulse diffused from the projector into the projectile. It is certain that the projectile is driven by the projector, and one

part of the medium is driven by the part struck by another; but the dispute is not about the first impulse, which comes from the projector while the projectile is conjoined to it, but about the impulse and motion by which the projectile is moved through the medium after being sent forth and hurled by the projector — by what, namely, it is moved: by the projector, by the medium, or by some other extrinsic thing. The common run of philosophers asserts that the impulse is a certain quality of the first species of quality, contained under the category of disposition, instilled into the projectile by the projector — by whose duration the projectile is moved, and by whose cessation its motion ceases — whether the projector is present or absent, alive or dead. For it is not of those things that depend on the efficient cause both in being and in becoming, as light depends on the luminous body, but only in becoming and not in being — as is plain from a sound emitted, whose cause, even if it perishes, nevertheless persists for at least a short time, as when the sounding body is broken the sound still exists and is heard.

First Assertion: The motion of projectiles is not caused by antiperistasis. So Aristotle in *8 Phys.*, *cap. 10*, *T. 82*, and this is deduced from Scotus in *4 dist. 6, quaest. 6, in fine E*. This is proved thus: first, antiperistasis is the siege and encirclement of a weaker and more infirm body besieged and encircled by a stronger and more potent body besieging and encircling it; but such siege and encirclement does not cause the motion of projectiles; therefore the motion of projectiles does not occur by antiperistasis. The major is known through the place from definition to defined. The minor is evident: by antiperistasis the besieged and encircled body is merely constricted and narrowed by the besieging and encircling one. Second: antiperistasis occurs because of contraries fighting against one another, of which one is stronger than the other; but antiperistasis can occur without any motion of projectiles — as in winter, when water in a well grows warm, and in summer grows cold. Moreover, antiperistases sometimes occur in clouds, as thunder indicates, even though no motion of projectiles takes place; therefore projectiles are not set in motion by antiperistasis.

Second Assertion: The medium — whether air or water — is not the adequate and sufficient cause of the motions of projectiles, but only a cooperating one. The Doctor in the passage cited does not appear to dissent from this. This is proved thus: first, with the surrounding and ambient air unmoved, a projectile is moved — as when no wind blows and yet someone hurls a stone through the air, the hurled stone is moved through it; indeed, even with the air moved, if the projectile is of great weight it is not set in motion in it; therefore it is a plain indication that the ambient air or any other medium is not the total and adequate cause of the motion of projectiles. And all the more so: if a weapon is hurled in a vacuum — which it is not improbable that it is possible to do — then, with no medium intervening, there will be motion of the hurled weapon; therefore the motion of a projectile is not derived from the medium. Second: a

wheel, a top, and things that spin rapidly in a circle are not moved by the surrounding air, as is seen with the eye. Moreover, it seems incredible — indeed, impossible — that enormous and heavy cannon balls should be moved by the surrounding air; for these demolish very strong walls and knock down high towers, and by their blows all other very robust things are overturned. And a boat proceeds against the current of a river and against an adverse wind; therefore the motion of projectiles does not proceed chiefly from the medium.

Third Assertion: The motion of projectiles proceeds from a power impressed upon the projectiles. This is indicated by the Doctor in the passage cited above, and *Ezekiel I* intimates it: "Where the impulse of the spirit was, there they went." And *James III*: "Behold, ships too, though they are great and are driven by strong winds, are nevertheless steered by a very small rudder, wherever the impulse of the helmsman directs." This is proved thus: first, for every produced effect some cause that produced it must be assigned — for nothing can cause itself; but the motion of projectiles is some effect, whose cause is neither antiperistasis, nor the ambient air, nor any other thing mentioned above; therefore from a sufficient disjunction it is the impulse of the projector, impressed upon the projectiles. Second: the greater the impulse of the projector impressed upon the projectiles, the more quickly and far the projectiles are carried — as we experience every day; therefore such an impulse is the precise cause of the motion of projectiles. Again: once that impulse is removed, the projectile is no longer moved; but while it lasts, the motion of projectiles likewise lasts; therefore it is their chief and precise cause.

Objection I: From 8 *Phys.*, T. just noted, and 3 *Caeli*, T. 28, the cause of the motion of projectiles is referred and attributed to the medium — namely, air or water. And this seems plausible, because one part of air set in motion drives another part, and so on with the rest; therefore the motion of projectiles is caused by the medium. Reply: perhaps Aristotle speaks of the cooperating cause, which no one denies to be the medium — not of the chief and precise cause, which he does not deny to be the aforesaid quality and impulse. But if he thinks otherwise on this and on some other matters, he is to be set aside, since experience and the arguments given above make the contrary known to us.

Objection II: The motion of projectiles is swifter in the middle than at the beginning and end — as is evident to all; but this arises from nothing other than the surrounding medium; therefore the medium is the cause of the motion of projectiles. Reply: this argument only proves that the medium body — whether air set in motion, its parts mutually impelled and struck — aids motion and makes it swifter and quicker in the middle, because more of its parts are impelled and set in motion in it than at the beginning and end. And in the motion of an animal, at the beginning the vital spirits are not all simultaneously joined and awakened as in the middle; at the end they nearly languish and are dissipated, and so its motion becomes slower.

Objection III: What is indifferent and indeterminate cannot determine motion toward a place upward, downward, or in a circle; but the impulse of the projector impressed upon the projectile is indifferent and indeterminate — for it does not respect an upper or lower or circular place more than another; therefore the said impulse cannot be the cause of the motion of projectiles. I grant the major. To the minor I say that the quality impressed upon the projectile is modified and determined by the projector. For this reason, at his pleasure, the projectile is rotated upward, downward, or in a circle.

You will ask: what is the cause of the cessation of the said quality? Reply: it is the resistance and violence of the subject upon which it is impressed — for since it is foreign and violent, it gradually fails, since nothing violent is long-lasting; to which is added the resistance of the medium and the opposition that weakens and depresses it; and therefore, like a sound, it lasts but a short time and quickly fails.

Question IV. On the Mover.

There remains no difficulty about the mover that has not been touched upon and discussed in the preceding sections; only a few things remain to be examined and decided about the first mover, who is God most good and most great, to be covered under a single article.

Sole Article. Whether There Is One First Mover, Immobile and Immaterial.

Aristotle speaks often about the first mover both in *8 Phys.* and at the end of *12 Met.*, where he investigates and examines its chief characteristics and peculiar attributes. Mayr in *1 d. 2, q. 3* observes that the existence of the first mover itself can be shown by a twofold medium — physical and metaphysical — and whether both together, or each separately, are sufficient for its demonstration is not a matter of unanimous opinion. For Thomas in *1 p., q. 8, art. 1*, the Coimbrans in *disp. 29, q. 6, §. 2*, and Ruvio in *8 Phys., Tract. de 1. motore*, think that the physical medium suffices to demonstrate it. But Scotus in *1 d. 2, q. 1*, and *d. 8, q. 5, §. Huius exclusiva, ante A.*, the Coimbrans in *8 Phys., c. 6, q. 1, art. 3*, and not a few others assert that the physical medium is not sufficient unless the second is added. Indeed, Bonetus in *2 Phys., c. 7* thinks that both are probable but neither is demonstrative or necessarily conclusive.

First Assertion: There is one first mover. So Aristotle in *8 Phys., T. 53*, and *12 Met., T. 55*, and Scotus both in the passage cited and in *Rep., 1 d. 2, q. 1*, and in *Tract. de I. principio, c. 3*, where Mauritius and Cavellus are found. This is proved thus: first, everything that is moved is moved by another, as stated in *7 Phys., T. 1*, and in other places cited in *art. 3 of the preceding question*; therefore since in things ordered per se the process does not go to infinity, as stated in *2 Met., T. 5, c. 2*, one must arrive at one first mover. This argument does not seem to be

effective and demonstrative, since very many things move themselves — such as animals, heavy and light things, and free agents — as I made plain in the preceding article. Moreover, if the stated argument proves anything, it urges only that there exists one first mover of the first heaven, which is not God but an Angel. Again, through it the Philosopher shows that the first mover moves by an eternal motion from the past, and that the generations of things are perennial and perpetual; but this teaching is false and contrary to orthodox faith. Therefore the physical argument of Aristotle does not evidently demonstrate the existence and unity of the first mover, who is God. Second: every being is either caused and dependent on another, or uncaused and independent and by itself. If the second, the intent is obtained — namely, the first being, the first cause, and the first mover, who is God. If the first, then either that upon which it depends and from which it is caused is uncaused and independent — and the proposition is had; or it is caused and dependent on another, and in this way I will inquire of that to infinity; but since one does not go to infinity, as has been said from *2 Met.*, *T. 5*, it is plainly inferred that there is one first mover by itself and independent of any other, unproduced and uncaused. This argument, drawn from *Metaphysics*, is more powerful and efficacious than the preceding one, as Scotus attests in *q. 3, prol.*, *§. Ad 1. arg. 2, q. V.*, and more fully in *d. 2, q. 2, q. ostensis*, and *§. Quantum ad 1. art.* And it evidently and sufficiently concludes, whatever Ruvio says in the passage cited. Add that in the *Metaphysics* it will be shown that there is only one God and that polytheism is impossible; and so it is aptly deduced that there is one first mover and one first cause and one independent being.

Second Assertion: The first mover is immobile and immutable. This is transmitted by Aristotle cited and Scotus in *1 d. 30, q. 2, §. Ad 2. q. M.* This is proved thus: first, from Sacred Scripture: *Malachi III*, "I am God and I do not change"; and *James I*: "With whom there is no change, nor shadow of alteration." Augustine in *contra epistolam fundamenti*, *c. 19*, and Damascene in *1 fidei*, *c. 3*, support this; and it is defined as a matter of faith in the Fourth Lateran Council, *c. Firmiter*. Second: what is most actual and supremely necessary can neither be moved nor changed, since change presupposes the potency to have what the subject previously did not have; but God is the most actual and supremely necessary being, possessing all perfections in act, and containing every good — according to *Exodus XXXIII*: "I will show you all good." And hence St. Anselm rightly infers in *Proslogion 3*: "God is that than which nothing greater can be conceived." Therefore He is subject to no motion or change.

Third Assertion: The first mover is spiritual and devoid of all bodily mass. This is defended by Aristotle toward the end of *8 Phys.* and in *12 Met.*, and by Scotus in *1 d. 8, q. 1 & 3*, and in *Rep.*, *q. 2*, and *d. 31, q. 3, §. Ad 1. principale*. Ferchius treats this at length and learnedly in many passages of *vestig.* *2, 1, 1, c. 3, 6, 1, 20*. This is proved thus: first, from Sacred Scripture: *John III*, God is called a spirit, who is free from matter and bodily mass. Hence the Savior says in *Luke XXIV*: "A spirit

does not have flesh and bones." Origen in *7 contra Celsum*, Augustine in *epist. 3*, and Anselm in *Monol., c. 20*, and others, support this, affirming that the opposite is a teaching contrary to the faith of the Church. Second: God is of infinite power; but infinite power cannot exist in a finite quantity — for it is not bounded by a finite limit; nor in an infinite quantity, which neither exists nor can exist, as I showed in *q. 5, art. 3, 1, 5*. Moreover, what is better and more perfect must be attributed to God, since in Him is the summit of all perfections; but it is better and more perfect that God be a spirit and incorporeal rather than material and corporeal, since the spiritual surpasses the material; therefore God is separated from all matter. More in the *Tract. de Deo uno, disp. 2*.

Objection I against the first assertion: from one and the same principle, several things cannot flow, as Averroes indicates in *8 Phys., com. 46*; but created and moved things are many, as is plain to all; therefore there is not one creator and mover of them. Reply: that saying assumed in the major is to be understood of a natural and necessary agent possessing only one power of operating — not of a free agent operating through multiple powers and faculties existing in it. But God voluntarily and freely established all things according to *Psalm CXIII*: "He has done all things whatsoever He willed."

Objection II against the second assertion: what is tied to a particular place and a particular mobile is moved — if not per se, at least per accidens — by the motion of that mobile; but God, as Aristotle testifies in *1 Caeli, T. 100*, resides in the outermost part of the primum mobile; therefore He is moved by the motion of the primum mobile, and thus God is mobile and mutable. Reply: granting the major, to the minor — the Philosopher is to be expounded as speaking of the first Angel, who is immediately present to the primum mobile to revolve it, and accordingly he enumerates as many Angels as there are moveable Heavens, as stated in *12 Met., T. 47, c. 4, sum. 2*. Or say that his meaning there is that God is not subject to the influences of the celestial orbs, and therefore he adds that He is not altered or subject to aging, and that He enjoys a pleasant and eternal life — which may He deign to grant also to us.

Books on the Heaven, the World, and the Elements, According to the Mind of the Subtle Doctor

Author: Brother Bonaventura Columbo of Nice, Minor Conventual, Doctor of Sacred Theology and Professor of the Same

Preface

The excellence, beauty, and usefulness of the knowledge contained in these books is narrated and announced clearly and elegantly by Solomon (*Wis. 7*), whose words are aptly adduced and lucidly expressed by the Seraphic Doctor in the prologue to the second book of the Sentences: "He gave me true knowledge of all that exists, so that I might know the disposition of the world and the powers of the elements, the beginning, end, and middle of the times, the alternations and changes of the seasons, the cycles of the years, and the positions of the stars." All of this is piously and learnedly signified and proclaimed by St. Augustine (*lib. de utilitate credendi, cap. 16*), (*in expos. psal. 99*), and (*lib. de vera Religione, cap. 29*): "For it is not in vain and idly that one ought to contemplate the beauty of the heaven, the order of the stars, the brilliance of the light, the alternations of day and night, the monthly courses of the moon, the fourfold tempering of the year, consonant with the four elements, the great power of seeds, the species and numbers of things that are born, and all things in their own kind preserving their proper measure and motion." The Parisian masters add at the beginning of this work, citing Aristotle, that we ought never to be more reverent than when treating of divine things; for if we enter temples composed, if when about to offer sacrifice we lower our gaze and perform every gesture of modesty, how much more ought we to do this when disputing about the stars, the constellations, and the nature of the heavens, lest we affirm anything rashly, imprudently, or in ignorance. Wherefore it is our pleasure to occupy ourselves in diligent investigation and careful examination of these matters, so that afterwards, when the course of this life has been completed, we may be able to rejoice in the clear vision and perfect enjoyment of their primary Author and cause. And in accordance with those three subjects we have proposed, we shall compose three books: the first will treat of the World, the second of the Heaven, and the third of the Elements.

Book I

On the World

What we call "World," the Greeks call *cosmos*, which means the same as ornament and beauty. The term "World" is used in the present context for the totality of created things, which is mentioned in (*Ecclus. 43*): "The beauty of heaven, the glory of the stars, the world illuminated by God on high." For this reason, some authors — such as Alexander and Thomas — hold that the total subject of the aforementioned books is the universe. Others, however, such as John of Magistris and the Parisians (*1. Cali, quaest. 1*), establish their adequate subject as simple body capable of local motion. We, however, must speak consistently with what we taught in (*1.1.q.3. art. 2*) and in the prologue of the same work. We raise three questions in this book: the first concerning the Creator of the World, the second concerning the creation of the World, and the third concerning the World as created by God.

Question I

On the Creator of the World

Article I: Whether God Could Have Created the World

Passing over the various errors and diverse heresies reported and vigorously refuted by (*Alph. 1. s. verb. creatura*) and (*l. 10. verb. Mundus*), the common run of philosophers appears to hold that God could not have created the World, on account of that well-known axiom inscribed by them in (*1. Phys. T. 33*), and again in (*1. de gener. T. 11*) and elsewhere: "from nothing, nothing comes." The opposite, however, is maintained by Catholic doctors, most notably (*Scot. 2. d. 1. quaest. 6*), and also (*4. dist. 1. quaest. 1*), as well as Orbelli, Gratianus, and the rest, who teach commonly and unanimously that God was able to found the universe from nothing.

First note that creation is used in two ways. Broadly, it is used for any kind of production — in this sense, in (*Gen. 1*) man is said to be created, even though he was formed from the slime of the earth (*ibid. cap. 2*). The Apostle makes mention of this usage in (*Rom. 8*), and Augustine uses it in (*l. 83. q. 67*) and in (*l. 1. contra Adversarium legis et Prophetarum, cap. 23*), saying that magistrates and cities are created; similarly the Pope is said to create Cardinals, and a bishop to create priests. Nor was Aristotle free from this usage, as is evident from (*4. de historia animalium, cap. 3*), (*2. de partibus animalium, cap. 2*), and (*2. de generatione animalium, cap. 4*): "the female always provides the matter, the male the creative power." Secondly, strictly and properly, creation refers to production from no pre-existing subject or underlying matter — in this sense the rational soul and the Angel are said to be created.

Note secondly that creation and making are used interchangeably, as (*Ferchius, 1. 1. def. cap. 1. n. 9*) notes from (*Aug. tom. 7. operum, l. 1. contra Adversarium legis*). This is plainly gathered from the book of Genesis; for in chapter 1 the divine chronicler writes and uses now the word "created": "In the beginning God

created the heaven and the earth," and now the word "made," as in chapter 2 of the same book: "God made the heaven and the earth." Again, in chapter 1 of the same work: "Let us make man," and shortly after: "The Lord created man."

Note thirdly, from (*Mayr. quaest. 9. quolib.*), after (*Anselm in Monol. cap. 8*), that something being made from nothing can be understood in four ways. First, subjectively — as form is made from matter and accident from a subject — and because nothing cannot be the matter or subject of anything, this mode of production is impossible. Second, successively — that is, after nothing something comes to be, as day follows night and light follows darkness — which is rightly explained by (*Scot. 1. d. 5. q. 2. R.*): a creature exists after nothing, that is, after the non-being of itself and of whatever is in it. And Aristotle seems to indicate something similar in (*2. Met. T. 7*): "at the Isthmian games, the Olympian games come to be" — that is, as Scotus interprets there, the Olympian games are celebrated after the Isthmian games, just as the feast of St. Francis is celebrated after the feast of St. Michael. This mode is possible, because God can confer being upon a creature that previously had no being — just as he can create light when light did not exist before — and this is narrated in (*Gen. 1*): "God said, let there be light, and light was made." Third, conversively — so that nothing is converted into something — and this cannot happen, because one opposite does not become the other, just as privation is not a habit, and night is not day. Fourth, negatively — as when one speaks of nothing, one is said to speak about nobody — and this mode too is reckoned impossible, like the first and third; only the second mode as explained above remains, according to which God is said to create something from nothing.

First assertion: God was able to create the World. So holds (*Scot. in the places cited above and in Rep. ibid.*). It is proved first: whoever can act immediately and operate independently can create, because creation in the proper sense, as stated in the first note, is production from nothing — that is, from no pre-existing subject. God, however, can act immediately and operate independently, since he is the first being from himself and independent; therefore he was able to create the World. Second: God was able to produce prime matter, since his power is infinite and productive of all producible things; and matter is creatable, since it is the first and ultimate subject of all forms. Furthermore, God can preserve an accident without a subject, and in fact does so in the Eucharist, as faith teaches; therefore he can also produce without a subject, and to produce without a subject is to create, as is clear from the definition of creation. Furthermore, God created the World; therefore he was able to create it. The consequence holds because the argument from act to power is valid. The antecedent will be shown in the next assertion. Moreover, a more powerful and more perfect agent requires fewer conditions than a weaker and more imperfect one, as can be shown in individual agents; but a weaker and more imperfect agent, in order to act, requires a subject; therefore the most powerful and most perfect agent can act without a subject, and hence can create.

Second assertion: God created the World. So holds (*Scot. ubi supra*), and it is a matter of faith, against Simon Magus, reported by (*Aug. in catalogo, haer. 1*). It is proved first from Sacred Scripture: (*Gen. 1*): "In the beginning God created the heaven and the earth"; (*Joan. 1*): "The world was made by him"; and (*Act. 7*): "God, who made the world and all things that are in it." Second, from the Council of the Lateran, *c. Firmiter, de summa Trin. et fide catholica*. Add the two Creeds, the Apostolic and the Nicene, in which it is expressly decreed that God is the creator of heaven and earth, of things visible and invisible. Third, from the Fathers, notably (*Aug. in operibus supra Gen.*) and (*contra epistolam fundamenti, c. 25*), and (*l. 2. de actis cum Felice, c. 18-19*), and (*l. de natura boni, contra Manich. c. 1*), and (*l. de fide, contra Manich. c. 43*). To these may be added (*Genebr. 1. Chrono pag. 2*). Fourth: God alone is independent from himself and through himself, needing no thing; therefore God alone founded this World from nothing. This is plainly indicated by the royal Psalmist (*Psal. 9*): "The gods of the nations are demons, but the Lord made the heavens" — where a distinction is drawn between the true God and false gods in that the true God created the heavens and all that is contained within their compass, whereas false gods did nothing of the sort, since they operate dependently upon a subject and possess limited power.

Objection I: if God can create something, he would be capable of change; but God cannot be changed; therefore he cannot create anything. The major of the sequence is proved: from not creating he would become creating, and therefore change would fall upon him. The minor has been shown in (*1. 8. Phys. q. 4. art. un.*). The major of the sequence is denied. In response to its proof, I say that by the same will by which God from eternity decreed to create the World, he created it in time; therefore he underwent no change — especially because change occurs when a subject is otherwise disposed through the reception of something newly received in it, whereas God receives nothing new through creation, but the creature alone receives being from God. Scotus illustrates this with the example of an opaque body newly produced and exposed to the light of the sun, which is newly illuminated by the sun, although the sun is in no way changed by such illumination. The same Doctor also illustrates this point in (*5. Met. q. 2*) with these words: "a voluntary agent can cause by an old will, unchanged, whenever it pleases, without any change in itself — just as if I now willed to sit tomorrow, I could sit tomorrow without any change in my will."

You will say: at least God receives a new relation of producer to the produced, just as through a new generation there is the relation of begetter to begotten. Hence (*Ambr. 1. Trin.*) says: "if the Father were to beget the Son anew, he would be changed by the acquisition of generation"; likewise, if creatures were newly created by God, he would be changed through creation. (*Aug. Serm. 102. de tempore*) adds: "Would that a sinful man might rise to repentance as quickly as God wills even to change a settled sentence." And (*ibid. Serm. 109*): "Repentance in God is said to be a change of sentence." And a little later: "the guilty one has changed; the Judge has changed his sentence." The major of the sequence is

denied; for, as will be stated below (*q. 2*), there is no real relation from God to the creature on account of his infinity, to which no addition can be made, as (*Scot. 1. d. 30. q. 2*) teaches near the end. To Ambrose I say that he speaks of things created, not of divine things, in which no change can occur. To Augustine I say that his words must be interpreted as meaning change not in God but in the sinner, and not in the cause but in the effect; and thus sorrow and the other passions are attributed to God not properly but metaphorically, as (*Lyr. in c. 6. Geneseos*) rightly interprets. Or, as others say, they are attributed to God with respect to the effect, not with respect to the affect.

Objection II: a cause that can act but does not act refrains from acting for some motive, since it awaits a suitable occasion for acting. But God did not create the World from eternity but in time, as will be shown in the next article, and no reason can be given why he created the World in time rather than from eternity; therefore he seems more likely not to have been able to create it at all. The answer is that in a free cause no other reason is to be sought beyond its freely acting will, which is the kind of will that belongs to God, which is the cause of all things created, according to (*Aug. 1. de Gen. contra Manich. c. 2*). Or, according to the same Augustine (*l. 1. contra Adversarium legis, c. 7*): "the sole cause of making these things was the goodness of God, because there was no necessity for him." Therefore he founded the World in time and not from eternity because he so willed. That this may be made clearer, we proceed to the next article.

Article II: Whether the World Was Created by God in Time

Concerning the origin of the World, (*D. Aug. 11. Civit. c. 2*) sets forth many and diverse opinions, which Vivès expresses there; and (*q. 106. novi et veteris testamenti*) and (*Genebrardus 1. 1. Chronol. pag. 31*) record them. Among these, the most celebrated is the opinion of (*Arist. 7. Phys. 1*) and (*8. eiusdem operis, c. 1*), and also (*1. Cali, T. 103*), and of his disciples, who hold that the World is eternal. All orthodox doctors oppose them, teaching that the World began in time; they were preceded by Plato and his followers, according to (*Bonet. 7. Phys. c. 2*), after (*Aug. 10. Civit. c. 31*) and (*12. eiusdem, cap. 14*), although Vivès there asserts that the Platonists disagree among themselves.

Note that "eternal" is sometimes taken for a long age or long period of time, as in (*Daniel 5*): "O king, live forever." Hence (*Horat. in Epist. cit. ab Aug. 1. 1. q. 9. super Gen. q. 31*): "He shall serve forever who does not know how to make use of little." Sometimes it is taken for that which has no beginning from the side of the past, as in (*Mich. 5*): "His going forth is from the days of eternity." Sometimes for that which has no end — called eternal from the side of the future — as in (*2. Petri 3*): "To him be glory now and in the days of eternity."

First assertion: the World was founded by God in time. This is presupposed by (*Doct. 2. d. 1. q. 3*) and other scholastics, who inquire there whether the World could have been created from eternity. It is proved first from Sacred Scripture:

(*Gen. 1*): "In the beginning God created the heaven and the earth" — where (*Aug. q. 112. novi et veteris testamenti*) translates "from the beginning of time." (*Prov. 8*): "The Lord possessed me at the beginning of his ways, before he made anything." And (*Joan. 17*): "Glorify me, Father, with the glory which I had before the world was made." Second, from the Lateran Council, *c. Firmiter, de summa Trin.*: "In the beginning of time God created each nature, that is, the celestial and mundane — or spiritual and corporeal — from which the whole World is compacted." Third, from the Fathers: (*Aug. 1. contra adversarium legis et Prophetarum, cap. 2*): "that there might be a beginning from which they began to exist; for they were not always coeternal with God, but were made and received the beginning from which they would begin to exist." And (*Ath. in oratione contra idola*) and all the others. And that Pythagoras and the Stoics acknowledged this truth is reported by (*Plut. 2. de placitis*), as well as (*Virg. 2. Georg.*): "I would believe that no other days shone at the first origin of the growing world, nor that it had a different course." Fourth, the first inventors of any art and science are narrated to have flourished at some particular time, as is established in (*Moyses l. Geneseos*), (*Athan. praecit.*), and (*Joseph. 1. Antiquit.*). If, however, the World had not had a beginning, there would be no first inventors of arts and sciences, since an infinite number of men would have preceded them among whom no first could be found. Moreover, human nature would by now have been greatly diminished and exhausted, as (*Aug. 11. Civit. c. 9*) observes. I add that it was fitting for God to have founded the World in time, so as to show that he acts freely toward the outside. Finally, it was proper that the creature should not be coeval and coeternal with the Creator; it follows, therefore, that the World was designed in time.

Second assertion: Aristotle expressly holds and teaches that the World is eternal. This is deduced from (*Scot. pallu praealleg.*) and maintained by the other scholastics, except (*Vorrilong. 2. d.*), who says that this fault was imputed to the philosopher by Averroes. (*Ferch. vestig. 8. num. 1*) writes the same and says that the Stagirite was speaking in popular fashion. But the mind of the philosopher himself is made explicit in (*7. and 8. Phys.*) and in other places, and is supported by arguments not few in number, to be adduced below. Moreover, the explicit sense of any author is established when he treats of a topic from a set purpose; Aristotle, however, disputes from express intention in the places noted above concerning the eternity of the World, which he there affirms and proves by many arguments; therefore such is his mind and opinion, from which (*Anaxagoras*) and (*Democritus*) do not appear to be far distant, since the former posits an eternal chaos or matter, and the latter posits atoms likewise eternal.

Objection I against the first assertion: in (*Tit. 1*), it is written that God promised eternal life, the highest happiness, before eternal times, as (*Aug.*) reads, or before the ages of the world, as the Vulgate has it; therefore if time is eternal, motion and the World are likewise eternal. The answer, following the interpretation of (*Lyranus*), is that God from eternity promised grace and glory to his elect, which afterwards at times determined and appointed by him he communicated and

furnished through the incarnate Word. Hence it is added in that place: "But has in due time manifested his word, in the preaching, which is committed to me." Or, as (*Aug. contra Priscillianistas*) says, those times are called eternal before which there was no time, as if from the constitution of the World.

Objection II: either God was able and willing to make the World from eternity — and then we have what we intended — or he was willing but not able, which is impossible since God is omnipotent; or he was able but not willing, which is also impossible, since God would then be envious, which is repugnant to him, since he is the highest good, freely communicating himself to creatures. The answer is that God could indeed have founded the World from eternity, yet willed to create it in time, both because it so pleased him and because he wished to show that he acts freely toward the outside, as (*Aug. l. de fide, contra Manich. c. 28*) intimates, saying: "God therefore suffers no necessity, nor does he make any necessity by which he acts, but acts by the highest and ineffable will and power." And in (*1. 83. q. 9. q. 27*): "Whoever asks why God willed to make the World seeks the cause of God's will." And in (*12. confes. c. 4*): "The will of God is the cause of all things."

Objection III: motion and time are eternal; therefore so also is the World; the consequence holds because those cannot exist without this. The antecedent is proved: in motion there is no first moment of change, nor in time a first instant, since time is the measure of motion according to before and after, and therefore before this time another time preceded it, since its parts are prior and posterior. The antecedent is denied. In response to its proof, I say that the World was created in an instant, and things that begin instantaneously begin through the first moment of their being, and cease through the last moment of their being, as stated above. Therefore, for the creation of the World it suffices that motion and time began through the first moment of their being, since before they did not exist. You will press: if the World was produced in an instant, and since an instant is the end of the past and the beginning of the future, it follows that before that instant there was time, and thus no beginning of time can be had. I say that Aristotle indeed asserts that an instant is the end of the past and the beginning of the future, but does not prove this; therefore with the same ease with which he asserts it, it can be refuted. Hence (*Bonet. 7. Phys. c. 3. §. Dissolutio autem*) rightly adds these words: "Aristotle imagines that time is a kind of successive circular line, which is not true; rather it is like a semicircular line, whose beginning is one now and whose end is another now, just as in a semicircular line there are two points that terminate it."

Objection IV: if time did not always exist, it is true to say that at some point time did not exist; but "at some point" denotes time; therefore there is time before time, and thus time never began but is eternal. The major is conceded; I distinguish the minor: negatively, I concede it; positively, I deny it. For just as before creation there is nothing — that is, the negation of the creature — so

before the making of the World, "at some point" is said to exist negatively. And (*Bacco 2. d. 1. q. 5*) says that an imaginary time preceded, which the (*Doct. Quol. 11. §. de secundo sub F.*) had already touched upon.

Objection V: heaven is the habitation and palace of God, according to (*Psal. 60*): "I shall dwell in your tabernacle forever." But God is eternal; therefore so also is heaven, in which he dwells; otherwise God would have had no dwelling in which to live. The answer is that heaven is called the dwelling of God because in it he is seen and worshipped by the Blessed, not because he needs it for habitation, since he is now everywhere, and before the constitution of the world was in himself, as I taught in (*art. 4. q. 3. 1. 6. Phys.*).

Objection VI against the second assertion: (*Arist. 1. Top. c. 9. or 12*) writes that it is a problem whether the World is eternal; therefore in (*7. and 8. Phys.*) and in (*1. Cali*), the philosopher speaks not assertively but doubtfully and tentatively when he says that the World is eternal. Likewise the same philosopher in (*3. Phys. sum. 3*) thinks he demonstrates that an actually infinite quantity is impossible; but if the World had been made from eternity, according to him, there would be an actually infinite number, since an infinite number of rational souls would have proceeded, which he himself apparently holds to be immortal (*3. anima 6*); and moreover, in (*4. pol. c. 13*) he asserts that at the beginning of the World there were kings on account of the small number of peoples — which plainly shows that he thought the World began in time. The answer is that in that place and in certain others he is speaking not in his own person but in that of others, namely the Pythagoreans and Platonists; but his mind is open and manifest from the testimonies cited above, in which he discusses that question expressly. To the subsidiary point, given that hypothesis, there would be an infinite quantity not actually and categorematically, but potentially and syncategorematically, as I showed at length in (*1. 4. Phys. quaest. 5*). To the other point about (*4. pol.*), I say that he spoke there in the opinion of others; especially since he does not there say a word about the origin of the World, and if he did speak about its beginning, the proper place would have to be sought where he treats that topic from express purpose, as the places cited above attest; therefore he is rightly condemned by the University of the Sorbonne, as (*the Parisian masters 8. Phys. fol. 81. q. 2*) testify.

First query: whether the World and the things contained in it were created by God successively or simultaneously? The answer is that they were produced simultaneously and in an instant, as is evident from (*Ecclus. 18*): "He who lives forever created all things simultaneously." Moses, who describes the series of all created things over an interval of six days, speaks to the capacity of a rude people and an untutored multitude. That Augustine held the same view is reported by (*Orbel. 2. d. 12*), and is evident from (*11. Civit. c. 31*), as (*Vivès*) notes there, and from (*4. de Gen. ad lit. c. 33*) and (*l. 1. contra adversarium legis, c. 9*).

Second query: in what month and on what day was the World founded? Some, among whom are the Hebrews cited by (*Genebr. 1. 1. Chronol. pag. 1 and 2*), say that the world was created in autumn, in the month of September. This could be urged from the end of (*Gen. c. 1*), where the sacred text mentions fruits with which the trees were laden and which men would eat for their living; fruits, however, are suitable for eating and consumption only in the autumn season. The more common opinion of others, affirming that the World was created in spring, in the month of March — the same month in which Christ the Lord was conceived and died — is that of (*Aug. 4. Trin. c. 5*), (*1. 83. q. 9. q. 56*), (*q. 55*), and (*q. 107 of the new and old testament*), (*Damasc.*), and (*Genebr. cit.*); and the Church sings in the first hymn of the Sunday matins: "On the first of all the days, on which the world was founded; or on which the rising Creator frees us from death through life." This is fitting, so that salvation might be restored to the world at the same time it had received it. The passage from Genesis cited for the former opinion does not compel a different view, since the works of God are perfect and he created the trees laden with flowers and fruits simultaneously.

Third query: whether the World will perish? The answer is that it will not be destroyed as regards itself as a whole and its principal parts, as (*Ecclus. 3*) intimates: "I have learned that all the works that God has made endure forever." But as regards accidents, it will be changed, because after the day of judgment the heavens will not move, nor will there be any more time, nor will celestial influences be emitted; and especially mixed things, above all animated ones, will be corrupted.

Article III: Whether the World Could Have Been Created from Eternity

Two extreme opinions circulate on this topic. The prior is that of (*S. Bonav. 2. d. 1. q. 2*), (*Ric. ibid. a. 3. q. 4*), (*Henr. Quol. 1. q. 7 and 8*), and others who deny that the fabric of the world could have been created from eternity. The posterior is that of (*D. Th. 1. p. q. 46. a. 2*), (*Caiet.*) and (*Naz. ibid.*), (*Aur. 2. d. 1. q. 2*), (*Dur. ibid.*), (*Tatar. 8. Phys. q. 1. dub. 2*), (*Suarez. disp. 20. Met. sect. 6*), and many others who affirm that there is no contradiction in the world's having been able to be made from eternity. The Scotists, however, with (*Scot. 2. d. 1. q. 3*) and (*in Rep. q. 4*), and the Nominalists with (*Ockham in eo loco q. 8*) and (*Quol. 4. q. 1*), judge both the aforesaid opinions to be probable, dissolving the reasons and arguments of both parties, though inclining more toward the affirmative, as (*Lych.*) and (*Fab. disp. 8*) note there. I know, however, that some — like the (*Dur. cit.*) — concede this of permanent things but deny it of successive ones; the other doctors affirm it of both.

Note first: it is not under dispute whether from eternity God possesses the power of creating everything possible and creatable — for since God himself is omnipotent and nothing accrues to him in time, since he is supremely perfect and immutable, clearly such a power belongs to him from eternity. Rather, the

question is whether such a power could have gone forth from eternity into the actual creation of something. Furthermore, something being produced from eternity can be understood in two ways: either from within, that is, because it is necessarily produced — as the Word of God the Father — in which case no creatable thing could have existed from eternity; or from without, because it is not repugnant to it to be produced if the will of God, which is his omnipotence, wills to produce it and communicate being to it. This distinction is indicated by (*Scot. nuper alleg.*) and is explained by (*Suarez ubi supra, num. 5*).

Note second: that one thing precedes another by nature can occur in two ways, positively and privatively, as (*Doct. 2. d. 1. q. 2. §. Resp. A. and q. 3. §. Tenetis autem. H.*) writes. For that which precedes another in being — without whose entity the entity of the other is prior — is said to precede by nature positively; as in man, animality precedes rationality by nature positively, since the rational animal presupposes animality as genus presupposes its differentia, and animal precedes man as genus its species. But that which does not pre-exist the other but would pre-exist if the other were not there is said to precede the other by nature privatively; just as in matter, privation would pre-exist if the agent were not to introduce or draw out a form from matter, through which matter is informed. Similarly in our case: non-being, or nothing, would precede the being of a creature unless the efficient cause, by conferring that being, were to prevent nothing from preceding the being of the creature — as the (*Doct. cit.*) subtly pursues, and (*Suarez, num. 11*) accepts.

Assertion: the World could have been created by God from eternity, not only as regards permanent entities but also as regards successive ones. This is the view of (*Scot. cit.*), though the opposite does not displease him. It is proved first from (*S. Aug. 6. Trin. c. 1*), cited by (*Scot. 1. d. 9. q. un. §. Ad q. dico sub A.*): "if fire or the sun had existed from eternity, the splendor proceeding from it would have existed from eternity"; the sun is the cause of its splendor and splendor is the effect; therefore, since God is from eternity, he could have created the World from eternity, just as if the sun had existed from eternity, it could doubtless have produced splendor from eternity. Augustine adduces this argument against the Arians who denied the coeternity of the Son of God with God the Father, and who affirmed that the Son of God was a creature, though nobler and more excellent than the rest. For if a producing thing and what is produced in created things — like fire and its splendor, the sun and its light — can be coeval, then certainly in divine things Father and Son are coeternal, Augustine concludes. Otherwise, this kind of argument on the part of the holy Doctor would be feeble and ineffectual, as (*Poncius disp. 50. q. 4. concl. prima*) mistakenly concedes. Augustine therefore rightly argues: if one created thing that is produced can be coeternal with another created thing that produces it, then the Son of God can be coeternal with the Father who produced him; indeed, he is coeternal with that same producing Father. And the same holy Doctor expresses this most aptly in (*3. contra Maximinum, cap. 30*) with these words: "Just as the fire that begets and

the splendor that is begotten are coeval, so also God the Father who begets and God the Son who is begotten are coeternal." The aforesaid Doctor adds from the Platonists (*lib. 10. Civit. cap. 31*): "if a foot had existed from eternity, the footprint pressed in the dust would have existed from eternity"; similarly, since God the Father is from eternity, he begot a Son coeternal with himself, and he could have founded the World from eternity.

Nor does it avail to say with (*Poncius praealleg.*) that the hypothesis is impossible; for given the impossibility of the hypothesis, the consequence of Augustine is still valid. For, as (*Aur. passu memorato*) aptly argues, if both premises of a conditional proposition are false and impossible, yet the consequence is valid — as "if a horse had wings, it would fly," whose categorical counterpart is true, namely "that which has wings flies or is able to fly." Similarly in our case this categorical is true: "a producing thing has, or can have, its product coeval with itself; and a begetting thing has its begotten coeval with itself," as (*Scot. ubi supra*) acutely pursues.

Second: a natural and necessary cause that is properly disposed and unimpeded can have an effect coeval with itself, as (*Aug. tract. 20*) explains and illustrates: "the flame that generates is coeval with the light that it generates, nor does the generating flame precede in time the generated light; from when the flame begins, from then the light begins. Give me a flame without light, and I will give you God the Father without the Son." The same he writes in (*lib. de symbolo ad Catechumenos, cap. 3*) and (*serm. 18. secundum Ioan.*). Therefore a free cause can also have an effect coeval with itself, because liberty, since it denotes perfection, does not prevent an effect from being coeval with its cause. But God has existed from all eternity and has the principle of producing outward things freely, which is his will; therefore from eternity he could have produced a World coeval with himself.

You will say: a cause necessarily precedes its effect, and therefore the effect cannot be coeval with its cause. But God from eternity would be the cause of the World, and therefore the World itself cannot be coeternal with him. Against this: it is not necessary that a cause precede its effect in time; it suffices for a priority of nature, which does not destroy the coevality of the cause with its effect, as is evident from man and his risibility, from the sun and its light and splendor. Therefore the objection is invalid. All the more so, since the Greeks teach that God the Father is the cause of God the Son, and yet assert together with orthodox faith that the Son is coeternal with the Father. The antecedent has been shown in (*lib. 4. Phys. q. 1. art. 1*).

Third: it seems no more repugnant for the World to be eternal from the side of the future than from the side of the past, since the reasoning is equal in both cases; but from the side of the future the World can be eternal, as no one denies; therefore it could be eternal from the side of the past.

Fourth: there would have been no contradiction; therefore it was possible. The antecedent is proved: for the repugnance would have been either on God's part or on the creature's part; but contradiction would have arisen from neither source. Not from God's part, who from eternity enjoys omnipotence; nor from the part of the World, which was producible both in time and from eternity. For correlatives are simultaneous by nature, according to the chapter *de ad aliquid*. If, then, God is from eternity productive of the World, then likewise from eternity the World itself is producible and creatable. Finally, if there were some contradiction in God's inability to found the World from eternity, it would already have been discovered by some philosopher; but no philosopher has yet devised any contradiction concerning the eternity of the World — indeed, Aristotle, the prince of philosophers, firmly maintains and vigorously contends for the affirmative side, as I showed clearly in the preceding article. (*John Major*) thinks much of this argument for corroborating our proposed assertion, and it is drawn from (*Augustine 11. and 12. Civit.*), adduced by (*D. Th. opusc. 27. de aeternitate Mundi*).

It would remain to deal individually with permanent and successive things; but since the reasons adduced above prove that permanent things could have been made from eternity, and the arguments of the objections in the preceding article appear to argue the same of successive things — which, if they prove anything in fact, prove it all the more of the possible — and since (*Aristotle 8. Phys.*) and in other places establishes motion as eternal, which is successive, and likewise time, which is successive and its measure, no repugnance is discerned in successive things having been able to exist from eternity.

Objection I: many testimonies of the holy Fathers, principally (*Ambr. 1. Exam. cap. 3*): "What is so inappropriate as for the eternity of a work to be joined to the eternity of God?" (*Damasc. 1. fidei, cap. 9*): "It is not fitting that what is derived from non-being should be coeternal with what is without beginning and always is." (*Basil. hom. 1. Exam.*) judges this to be blasphemy. (*Aug. 12. Civit.*) and (*Hugo Vict. 1. de sacram. cap. 10*) indicate the same. Their principal foundation is that they were disputing against the Arians, who suspected that the Son of God was a creature and coeternal with God the Father. They argued thus: a creature is not coeternal with the Creator; the Son of God is coeternal with God the Father; therefore he is not a creature. The minor was conceded by the Arians; the major was proved by the Fathers cited, because a creature is in time, as is clear from Sacred Scripture and as I showed plainly in (*art. 2 of this question*). I respond that the cited authorities of the Fathers can be interpreted in two ways: first, as speaking of what is in fact the case, not of what is possible, which is the matter under dispute; second, as capable of being explained as referring to coeternity from itself and independent — in which sense it is absurd to suppose that a creature could have been made from eternity independently of God, for only God is eternal from himself and independent. Therefore, given the hypothesis that the World had been created from eternity, it would still not have been from

itself but dependent on God. The foundation of the Fathers is that since the Son of God is begotten from eternity by the Father and is coeternal with him, and since every creature is in time, it follows plainly that the Son of God is not a creature, as the Arians maintained. Thus those Fathers were speaking of what is the case in fact, not of what is possible, which is what the dispute concerns.

Objection II: creation is a passage from non-being to being, since it is the production of a thing from nothing; and nothing precedes the being of the creature. Therefore no creature could have been created from eternity, since non-being would have had to precede being; but that which is eternal has no antecedent from the side of the past, since nothing precedes it. Consequently, if something had been annihilated, its being would precede nothing; therefore likewise, if something had been created from eternity, nothing would have preceded its being, and therefore it would not have been eternal. The major is conceded; I distinguish the minor: positively I deny it, negatively I concede it, as was explained in the second note. To the consequence, the parallel is to be denied, because annihilation presupposes the being of the thing positively, since it is a passage from being to non-being; but creation requires only nothing, which is the negation of a real positive entity; therefore it suffices that nothing precede negatively, which does not prevent the created thing from having been able to enjoy eternity.

Objection III: if the world could have been produced from eternity, it would either have begun to be or it would not have begun to be; but neither of these is possible; therefore it could not have been eternal. The major is evident. The minor is shown: if it had begun to be, it would not have been eternal, because what begins to be is in time; if it had not begun to be, it would not have been created, for what is created begins to be, and therefore is in time. The answer, given the hypothesis, is that the World would have received being from eternity, since between "begun to be" and "not begun to be" there stands "having received being from eternity"; and nothing would have preceded it positively, but only negatively, in the way stated above.

Objection IV: from (3. *Phys. Tit.* 32) and (9. *Metaphys. Tit.* 17), in everlasting things, to be and to be able to be do not differ; but the World, from what has been said, is everlasting; therefore if it could have existed from eternity it did exist from eternity, since to be able to be coincides with its being. The answer, following (*Scot. in expeditione illius tex. cit. Met.*) and (*ibid.* 3. *Phys. quaest.* 9), is that that axiom holds with respect to being and being able to be simply and substantially, but not with respect to being and being able to be in a qualified sense and accidentally — just as the sun can illuminate everything illuminable, yet not everything illuminable is illuminated; and the moon can be eclipsed, yet it is not always eclipsed; and a wall can receive whiteness, though it is not always white. Or, better and more aptly to our purpose: in eternal things, of which kind is God alone and what is in him, to be and to be able to be are identical with respect to

what is internal, I concede; with respect to what is external, I deny. Thus in divine things, to be able to generate and to generate are identical, as are to be able to spirate and to spirate; but to be able to create and to create are not the same. For God could have created things from eternity, yet did not create them from eternity but in time. The reason is given: the power of generating looks to that which is internal; but the power of creating looks externally to producible and creatable things.

Objection V: if the World could have been made from eternity, there is no contradiction in an actually infinite number of rational souls; and there is no contradiction in an actually infinite production and existence of things, nor in an actually infinite number of years, months, days, hours, and other actual infinities — all of which things seem absurd and contradictory; therefore the World could not have existed from eternity. The aforementioned and similar consequences are to be denied. For if they had been infinite, they would have been so in potency, not in act. The reason is that, from what was said above in the question on the infinite, an actual infinite is that to which no addition can be made; but given any number of rational souls and of other things, something could be added — that is, other things could have been created, since the power of God is infinite and inexhaustible. This response is drawn from (*Scot. 2. Met. q. 6. §. Ad rationes*), and is embraced by (*Trombet. Tract. de pluralitate animarum*), although (*Baff. 4. d. 43. q. 2*) follows the contrary opinion and (*Aug. 12. Civit. c. 20*) indicates it.

Question II

On the Creation of the World

The chorus of scholastics, notably (*Scot. 4. Rep. d. 13. q. 1*), (*Mayr. 2. d. 1. q. 3*), (*Aur.*), (*Ockham*), (*Gabriel. ibid. q. 1*), and (*Gad. Quol. 12*), divides creation into active and passive, of which we shall treat in the present question.

Article I: What Creation Is

That there is creation is established from what was said and shown in (*art. 1 of the preceding question*), where I asserted that God was able to create the world and in fact did create it. What has been created was created by creation, just as what has been produced and generated was produced and generated by production and generation. Creation is therefore conceded, which is defined by (*D. Aug. 12. Civit. cap. 2*) and (*Damasc. 1. fidei, cap. 8*) as the production of a thing from nothing; and this definition, which is adapted to creation in the proper sense, is accepted by all scholastics, notably (*Scot. 2. dist. 1. quaest. 2. §. Respondeo. ante A.*) and (*4. dist. 1. quest. 1. §. Ad argumenta PP.*) and (*in Rep. ibid.*). There is, however, no small controversy among the doctors as to whether creation belongs to substance alone or also to accident. For (*D. Thom. 2. 4. part. q. 45. art. 1*) and his disciples maintain that it belongs only to a subsisting thing, which is substance. (*Scot.*,

however, 2. dist. 34. §. *iste qq. A.*) and (4. q. 1. §. *Ideo dici potest. LL.*) and (1. d. 17. q. 3. §. 6. *propter tertiam, Sub Y.*) and his followers teach that creation extends not only to substance but also to accident that is free of matter and spiritual.

Note that certain forms depend upon matter both for their being and their becoming — such are material or substantial forms, like the form of a stone, or accidental forms, like the light of the sun. Other forms, on the contrary, depend on matter neither for their being nor their becoming — such is the rational soul, which, although it is in matter, namely in the body, is separated from it after the death of man and exists and subsists by itself. This distinction is indicated by (*Arist. 2. Phys. T. 18*), who teaches that certain forms can be abstracted from matter and others cannot. Furthermore, a division of forms into natural ones — which are produced by the power of a natural agent and are said to be drawn out from the potency of matter — and supernatural ones — which are produced by a supernatural agent, namely God, such as grace and the other supernatural gifts — ought not to be omitted, and it is now in dispute whether the latter fall under creation.

Assertion: creation belongs to accident as well as to substance, when the accident is produced immediately by God. The assertion is twofold, and (*Doct.*) maintains it in the places cited above. The first part is evident from the preceding (*q. a. 1*), in which I proved that God created prime matter, the Angel, the rational soul, and the rest that are properly substances. God is an independent agent; therefore he can act without any pre-existing subject, which is to create. The second part is urged first: what is immediately produced by God is created; but certain accidents are immediately produced by God; therefore they are created. The major is evident: to create is just the same as to act without any means and pre-existing subject. The minor is proved from (*Psal. 83*): "The Lord will give grace and glory." And it is a common axiom of theologians that grace is created, as even the adversaries acknowledge, according to (*Fabro 4. disp. 2. c. 3*); and this is deduced from (*D. Paul. Eph. 2*), who calls grace a creature. For it is a supernatural gift produced by God alone; therefore it is properly created. Second: creation belongs to that which annihilation also belongs to, just as generation belongs to that which corruption also belongs to; but grace is not corrupted by sin in man, because corruption is the change of one form into another form, according to the axiom "the corruption of one is the generation of another." But when grace is lost, nothing new is generated; therefore grace is not corrupted but annihilated. Nor does it migrate from one subject to another, as no one denies; nor does any creature concur in its production, since it is not contained within the sphere of creaturely activity, since it is a participation of the divine being; therefore creation attains to it, and consequently an accident — especially an absolute accident that can be really separated from its subject — falls under creation.

Objection I: the being of an accident is to inhere, according to (*7. Met. T. 3*); but if some accident were created, it would participate in its own proper being; therefore no accident can be created. The answer is that Aristotle there teaches that the cause of natural accidents is substance, as (*Scot.*) interprets, and that he is not speaking of supernatural accidents, which Aristotle did not know.

Objection II: creation is of subsisting things; but no accident subsists by itself, for that is proper to substance; therefore no accident is created. The major is to be denied; for it suffices that they be beings simply and absolutely, and that they be capable of existing by themselves at least by divine power, as is the case with the accidents of the most holy Eucharist.

Article II: Whether Creation as Action Is a Real Being

(*Aureolus 2. d. 1. q. 2*), (*Ockham ibid. q. 1*), (*Gabriel concl. 4*), and the other Nominalists hold that creation as action is a real being. But (*Scot. 4. d. 13. q. 1. ante §. de secundo*), (*Faber 2. disp. 3. cap. 2*), (*Mayr. quest. 3*), (*Gad. quol. 12*), and others, among whom is (*S. Th.*) and his followers, hold that creation as action is a relation of reason.

Note first that certain things belong to God from eternity — such as wisdom, infinity, and the rest, both essential and notional; but certain things belong to him in time — such as being Creator, Governor, and Lord. These things are said of God not because something real newly accrues to him — for then he would be mutable — but on account of a new termination toward a creature founded and newly created in time. This can be illustrated by the example of a work that is called human, not because there is something of humanity in it, but because such a work was made by a man and the productive power of man is terminated toward that work.

Note second that creation as action is used in two ways. In one way formally — that is, for a relation of reason grounded in the divine will and in its act of willing, and terminated toward the creature. In another way fundamentally — namely, for the divine will and its act of willing, by which it produces the creature. Likewise, creation as passion is understood in two ways: formally, for the dependence or real relation of the creature toward the Creator; and fundamentally, or for the essence and nature of the creature produced and created by God the Creator.

Assertion: creation as action formally is a relation of reason; fundamentally, however, it is a real being. The assertion is twofold, and (*Doct. ubi supra*) maintains it. The first part is proved first: every being is either real or of reason, as (*Vallo tract. form. fol. 14 and 78*) notes before others. But creation as action is not a real being, because since it belongs to God, it would be either his essence or his relations of origin; and since these are eternal, creation as action would belong to him from eternity, which contradicts the truth shown in (*art. 1 of the preceding question*). Therefore, creation as action formally is a being of reason. Second: the

independent and the dependent, the infinite and the finite, are so related that the finite and dependent regards the infinite and independent by a real relation, whereas the independent and infinite regards the latter by a relation of reason — as (*Doct. 1. d. 30. q. 2. §. Ad argumenta 2. q. Q.*) shows acutely and perspicuously. Third: if no relation of reason accrued to the Creator, beyond doubt a real relation would accrue to him; and since this would be in time, the Creator himself would have something real anew that he did not have before, and thus change would fall upon the Creator himself, which is false and absurd; therefore a relation of reason is to be established. The second part is acknowledged, since creation as action taken materially and fundamentally, from the second note, means nothing other than the divine will or its act of willing, which no one doubts to be a real being; thus taken, creation as action is a real being.

Objection I: what is truly and really denominated by another thing, setting aside any operation of the intellect, that other thing is a real being; but God is truly and really denominated through active creation as creating and Creator, setting aside all operation of the intellect; therefore active creation is a real being. I distinguish the major: what is really denominated by intrinsic denomination, I concede; by extrinsic denomination, I deny. I apply the same distinction to the minor: God through active creation is denominated by intrinsic denomination, I deny; by extrinsic denomination, I concede. For God is not formally denominated creating by creation existing in him, but by creation terminated toward the creature — just as a bench is called human because the operation of man is terminated toward that bench, as is clear from the first note. You will press: if God is called Creator because he terminates the relation of the creature, then active creation is not a relation of reason. The consequence is to be denied if one speaks of creation formally taken, which is what is under discussion; otherwise if one speaks of creation fundamentally accepted, as I made clear in the second note.

Objection II: the generator and the generated in divine things are also related by mutual relation; therefore the Creator and the creature also regard each other mutually by a real relation, and thus active creation is a real relation, just as passive creation. The parallel is to be denied, since the aforesaid relations of origin are constitutive of the divine persons, whereas the relations of Creator and creature are adventitious; but something real cannot newly accrue to God, since he is immutable and infinite; therefore there is no real relation from the Creator toward the creature, but there rightly is from the begetter toward the begotten and from the spirator toward the spirated.

Article III: Whether Creation Is a Change

Some, among whom is the Seraphic Doctor (*2. d. 1. art. 3. q. 1*), hold that creation is a change. But (*Scot. 2. dist. 1. quaest. 5. §. Secundum primum s. ad 5.*) and (*4. dist. 11. quest. 1. art. 3*), (*Mayr. 2. d. 1. q. 2*), (*Faber ibid. disp. 3. cap. 2*), and other scholastics teach that creation is not properly a change.

Note from (*Scot. in 2. passu alleg.*) that change can be used in two ways. First, broadly and improperly, for any new acquisition of a thing, whether substantial or accidental — in this sense the production of any thing can be called a change. This is perhaps what (*Arist. 5. Phys. 7*) had in view when he says that something can be changed in four ways: from non-subject to subject, or from subject to non-subject — the former is generation, the latter is corruption — or from subject to subject, as alteration, or from non-subject to non-subject; and this last combination is really not a change, since its terms are neither contrarily nor contradictorily opposed. Second, precisely and properly, for the new actualization of a form that a subject receives, whereby it is otherwise disposed now than before (*6. Phys. 32 and 74*); in this way, change always requires a subject, whether the thing passes from one form to another form, or from privation to form.

Assertion: creation is not properly a change. (*Scot. praecit.*) supports this. It is proved first from (*D. Greg. 5. Mor. ad medium et finem*): "change is a progression from one to another" — that is, according to the interpretation of (*Rich.*), from one real extreme to another real extreme; but creation does not participate two real extremes, since its terminus from which is nothing; therefore creation is not properly a change. Second: change in the precise sense, as noted above, is when something is otherwise disposed now than before through the reception of some form; but through creation a thing is not otherwise disposed now than before, since the thing did not exist before but received being through creation itself. Furthermore, change requires a subject in which it occurs; but creation excludes a subject, since, from what has been said, it is defined as production from nothing, that is, from no pre-existing subject. Therefore creation is not properly a change. Moreover, creation is contained under no species of change, as is clear by induction; for it is neither generation, nor corruption, nor alteration, nor local motion, which are treated in the postpredicaments and in (*5. Phys. T. 7. and elsewhere*), and of which I made mention above in the note.

Objection I: (*D. Aug. 12. Civit. cap. 1*) writes that what was made from nothing is mutable. (*S. Damasc. 1. fidei, cap. 3*) adds that things creatable are subject to turning; therefore if created things are subject to turning and change, creation is likewise a turning and change. The answer is that these and similar authorities are to be taken of change broadly understood, not of change in the strict sense.

Objection II: there is no transition from contradictory to contradictory without change, as is plain in the case of a wall that passes from non-white to white through change or the reception of whiteness; but through creation a creature passes from non-being to being; therefore creation is a change. (*Doct. 1. dist. 39. §. Ad 1. arg. 3. q.*) answers that this is valid for successive things and not for simultaneous ones. For the wall must first be without whiteness and then be adorned with it. Since, however, a creature does not in any way exist before it is created, its creation is not a change.

Objection III: a change is when something is otherwise disposed now than before, as was stated above; but through creation a creature is otherwise disposed now than before, since before it was not and now it is; therefore creation is a change. The answer is that the definition of change is to be understood presupposing the existence of the thing; for what is subject to change is subject to the received or to-be-received form and to its privation; for this reason I noted above that change in the strict sense requires an existing subject in which it occurs. Since, however, creation is production from no pre-existing subject, it is therefore not properly a change.

Article IV: Whether Creation Is a Transient Action

(*Bilor. relati 1. p. quaest. 45. art. 3. dub. 1*) and others hold that creation, broadly taken, is an immanent action. But (*Aur. 2. distinctione 1. quaest. 2. art. 1*), (*Greg. ibidem quaest. 6*), (*Ockham 1. dist. 43. quaest. 1*), and (*Conimb. 8. Phys. cap. 2. quaest. 1. art. 3*) assert that creation is a transient action. What is to be said on this point according to Scotus and the truth will be opened up and decided by what follows.

Note that creation is not properly an action. For an action, according to the Author of the six principles (*cap. 2*), is defined as that according to which we are said to act upon what is subjected to us. And according to (*Scot. 4. dist. 13. quaest. 1. §. Ad huius autem sub H.*): "an action is a relation extrinsically accruing from the transmuting to the transmuted"; but creation, since it presupposes no subject, is not rightly considered a proper action, which presupposes a subject upon which the agent acts. Therefore, if creation is not truly an action, it is certainly neither an immanent nor a transient action, as is plain from the canon we taught and explained in (*Epit. lib. 3. quaest. 3. art. 3.*): when the genus is removed, the species is removed too. It is called an action in the broad sense — and likewise passion with respect to the created thing. Furthermore, let the double acceptance of action stated and explained in the second article of this question be recalled: fundamentally — that is, for the act of the divine will — and formally — for a relation of reason of God creating toward the creature.

Assertion: action fundamentally accepted is an immanent action; formally taken, however, it is a transient action. This is deduced from (*Scot. ubi supra*). The first part is evident because, thus accepted, it is the act of the divine will, which is from eternity really identified with God himself. Furthermore, an immanent action does not have a terminus, but is itself the terminus of production (*9. Met. Tit. 16*), where Aristotle calls immanent operations the termini of powers; but creation as action fundamentally taken does not have a terminus; therefore creation fundamentally taken is an immanent action. The second part is urged first: a transient action is one that regards the product outside the agent from which it proceeds, as its name indicates; but creation as action regards the creature, which is outside the creating God; therefore it is a transient action. First: things that are in time are called actions toward the outside, as the

scholastics commonly teach, distinguishing the works of God toward the inside and toward the outside; but creation is in time and regards a work toward the outside; therefore it is a transient action.

Objection I: creation as action is the volition of God; for God through the act of his will creates whatever he wills to create. Hence (*D. Paul. Eph. 1*) writes that God does all things according to the good pleasure of his will; but the volition of God is immanent; therefore creation as action is immanent as well. I concede the major; I distinguish the minor: the volition of God is an immanent action insofar as it regards what is internal, I concede; insofar as it regards what is external, I deny. Or say that the argument concludes with respect to creation fundamentally taken, but not with respect to creation formally taken.

Objection II: if creation were a transient action, it would be in the creature; for it would pass from God into the creature itself; but creation is not in the creature, otherwise the creature would create; therefore creation is not a transient action. The answer is by denying the consequence of the major, since only passive creation is located in the creature — especially according to (*Scot.*), who holds that action exists in the agent.

Article V: Whether Creation Is Distinct from the Created Thing

There is no difficulty about creation as action, since this — fundamentally — is the act of the divine will, and formally a relation of reason, and therefore without doubt differs from the created thing. The question is about passive creation, which is the real relation of dependence of the creature upon the Creator. For some, like (*Aur. 2. d. 1. art. 2*), defend that creation is something intermediate between God and the creature, just as a road mediates between two extremes that bound it. (*Thomists 1. part. q. 45. art. 3*) establish between creation and creature a real distinction. But (*Scot. 2. dist. 1. quaest. 5. §. Ad q. istam. M.*), (*S. Bon. ibidem art. 3. quaest. 2*), (*Ric. art. 1. quaest. 4*), and very many others teach that passive creation is really identified with the creature but formally distinct from it.

Note first from (*Scot. 2. dist. 1. quaest. 2. §. Ad 1. arg. princip. D.*) that a cause acts immediately upon its patient, not acting through some absolute or relative form as intermediate, but by a principle and power inhering in itself; therefore that which is absolute in the cause is followed immediately by what is absolute in the effect, and the rest follow from these — such as the relation of cause to effect and vice versa. Hence, creation is not something intermediate between God and the creature by which the creature is created by God, since being a relation, it does not precede but follows, arising as it does from the positing of the extremes.

Note second from (*the same Doct. cit. quaest. 4. §. Ad illam primam quest. Q.*) that creation presents several relations: one toward the creating and causing God, and this is really identified with the created thing; another toward the non-being

that precedes — and this is twofold. Either toward the non-being that immediately precedes the being of the creature by some duration, and this relation is really distinct from the created thing, since it ceases while the creature persists in its being; or toward the non-being that precedes mediately, indistinctly, and indifferently, and this relation remains as long as the creature remains, and therefore is really the same as it.

First assertion: passive creation does not mediate between the Creator and the creature. This is deduced from (*Scot. in 2. praealleg. q. 2. D.*). It is proved first: everything that exists is either from itself or from another; passive creation is not from itself, since only God is such; therefore it is from another, and thus it does not mediate between Creator and creature. Second: if passive creation were something interposed between God and the creature, it would be either something eternal or something temporal; but it can be neither; therefore it does not mediate between them. The major is evident; the minor is ready at hand, since nothing except God is eternal, and nothing temporal exists unless it is created. The Council of Sens adds its weight, decreeing that ideas do not mediate between God and the things ideated, and excluding altogether any medium between the creature and the creating essence.

Second assertion: passive creation is not really distinct from the created thing, but only formally. The assertion is twofold, and (*Doct. ubi supra, quaest. 4. §. Ad quaest. istam. M.*) maintains it. The first part is proved: things that are inseparable from one another by any power — whether natural or supernatural (except for those among which there is essential dependence, such as a whole and its parts) — are not really distinct; but passive creation and the created thing are such; therefore there is no real distinction between them. The major, beyond being explained and proved elsewhere, can also be urged from the opposite: things that are divisible and separable from each other are really distinct, as is clear from matter and form, from place and the located thing, from Peter and Paul, and the like; therefore conversely, things that are indivisible and inseparable are not really distinguished. The minor is proved: passive creation is the relation of dependence of the creature upon the Creator; but it is impossible for the creature to exist without that dependence, since it is formally a dependent being and God is independent. Furthermore, those things of which one can exist without the other really differ; the same thing cannot simultaneously exist and not exist, be and not be — for this is opposed to the first principle, and it is a safe way of arguing through contradiction, as one may see in (*7. Top. cap. 8 and elsewhere*). Conversely, those things of which one cannot exist without the other do not really differ; passive creation cannot exist without the created thing, nor the created thing without passive creation, since the former is essentially its dependence and the latter is what is dependent; therefore they are not really distinct.

The second part is proved first by the authority of (*D. Aug. 7. Trin. 2*): "everything that is said relatively is something, except the relation"; therefore since the creature is referred to God, it plainly follows that the essence and substance of the creature differs formally from the relation by which it is referred to the Creator. Second: the absolute differs at least formally from the relative, because the former is toward itself, the latter is toward another — as the same (*Aug.*) affirms at the beginning of (*lib. 3 of the same work cited*); but the essence of the creature is an absolute entity, especially if it is substantial, and passive creation is a relative entity; therefore they differ formally. Third: a distinct definition or description indicates a distinct formality, since a definition is a discourse expressing the nature and formality of a thing; but the definition of passive creation is different from the definition of the creature, because the former is formally a relative being and the latter a being that is absolute; therefore there is a formal distinction between them.

Objection I against the first assertion: between begetter and begotten there is a middle, namely generation, as (*Arist. 2. Phys. Tit. 14*) and (*3. eiusdem operis, T. 21*), (*5. Tit. 2.*), and elsewhere, teaches; therefore between creating and creature creation also mediates. The parallel is drawn because just as the creator creates through creation, so the begetter generates through generation; but the latter is established as a medium and way between begetter and begotten; therefore the former too is a medium between creator and creature. Consequence I: what a thing is made by and what it is differ, as no one denies and is plainly evident — for generation is that by which the generated thing is generated, and the generated thing is what is generated; likewise, action is that by which the agent acts, and the effect produced by it is what is acted upon; similarly, creation is that by which the creature is created, and the creature is what is created.

Consequence II: what passes away is distinct from what remains, as is clear from privation, form, and matter, and also from motion and the moved thing; for while matter persists, privation arrives and form arrives; and while the moveable persists, now motion inheres in it and now rest. But creation passes away, while the created thing and creature remains after creation; therefore creation mediates between it and the Creator. The parallel is to be denied, because in generation something is always pre-required and presupposed — in divine things the essence, in created things matter; but in creation nothing is presupposed, since it is production from nothing, and only its terminus is touched, as the (*Seraphic Doct. passu alleg.*) excellently pursues. The same must be said to the first consequence. To the second, satisfaction is given through the double acceptance of creation stated in the second note. For if creation is taken for the respect of the creature toward the non-being that immediately precedes it, in this way the created thing passes away and creation ceases, just as when the terminus is reached, motion ceases; but if it is taken for the respect of the creature toward the non-being that mediately precedes it, this remains as long as the creature remains.

Objection II against the second assertion: (*Aug. 5. Trin. cap. 5*) writes that in created things, what is not said according to substance must necessarily be said according to accident; therefore since the relation of passive creation is not substance but accident, it follows plainly that it is really distinct from the created thing. The answer is that Augustine takes accident there not for a being inhering in a subject, but for something extraneous — that is, what does not enter into the essence of a thing but follows from it. You will say: a relation is located in the predicament of accident, which truly inheres in a subject; passive creation is a relation; therefore it is properly an accident taken as a thing inhering in a subject. The answer is that the objection applies to predicamental relation, not to transcendental relation, such as passive creation, as (*Scot. 1. d. 2. q. 2*) and (*A. d. 43. q. J. §. De tertio*) indicate; for being is first divided into uncreated and created before it is divided into the ten predicaments, which are the series of created beings.

Article VI: Whether Creation and Conservation Are the Same

Some, followed by (*Aur. 2. d. 1. q. 2. a. 2*) and others, to whom (*Ric. ibid. q. 1. art. 2*) lends support, assert that creation and conservation are diverse habitudes and really distinct relations. The Seraphic Doctor in 2 is cited for this opinion by (*Gadium gnol. 12*), but I find nothing there that supports it. (*Scot., however, quol. mox alleg. art. 1*), (*Lich. ibid.*), (*Faber 2. disp. 8. c. 3*), (*Mayr. q. 4*), (*Orbel.*), and the other Scotists firmly assert that creation and conservation are one and the same real relation, entirely really distinct.

Note that since creation is the production of a thing from immediately presupposed nothing, and conservation is the continuation of the same pre-existing thing, beyond the real relation by which the creature is referred to God the Creator as effect to its efficient cause, there are implied two relations of reason: one toward the non-being that immediately precedes, by reason of which it is said to be created in the first instant in which it is created; another toward the non-being that mediately precedes, by reason of which it is said to be conserved, because that being which the thing receives in the first instant through creation persists and endures in the second and other subsequent instants, and therefore it is said to be conserved. Furthermore, observe that these two latter relations are called relations of reason not because they are fabricated by the intellect, but because one of their extremes is not real and positive, as (*Scot. in postpredicam.*) says that contradiction and privation are relations of reason because one of their extremes is negative or privative. For a real relation arises from two real positive extremes; if either is negative or privative, the relation is called one of reason.

Assertion: creation and conservation are a single real relation of the creature to the creating and conserving God. This is defended by (*Doct. cit. §. De primo A.*). It is proved first from (*D. Aug. 8. supra Gen. ad lit. c. 12*): "Air, in the presence of light, has not been made luminous but is made luminous by the illuminating sun. For

if it had been made luminous, it would remain luminous after the sun withdraws; but it does not remain luminous, as experience shows; therefore it has not been made luminous." Similarly, the creature has not been made by God but is continuously being made, because it needs God's help and sustenance, without which it would instantly be reduced to nothing, as (*Aug. 4. de Genesi cap. 14*) attests. Therefore, if the creature is always being made while it is being conserved, creation and conservation are not distinct from one another. (*Avic. 6. Metaphys. capite primo*) adds: "an effect needs the giver of its being always and ceaselessly for as long as it has being." Therefore, if to be conserved is always to receive being from the conserver, and to be created is to receive being from the Creator, no difference between creation and conservation seems to be interposed. Second: the unity and identity of a relation is drawn from the unity and identity of its terminus and foundation, as I have often stressed; but the terminus of both creation and conservation is entirely the same — namely, the act of the divine will by which it creates the creature and conserves it — and the foundation is likewise the same — namely, the existing creature; therefore creation and conservation are one and the same relation. Furthermore, there is one and the same dependence of one total effect upon one total efficient cause; therefore also there is only one dependence of the creature upon the creating and conserving God. The antecedent is clear from (*l. 1. de causis, quaestione secunda, articulo tertio*); the consequence is deduced. For conservation pertains to the efficient cause, as is evident from light, which, just as it depends on the luminous body in its coming to be and in its conservation, so also does the creature depend upon God, as (*Aug. praecit.*) plainly expounds.

Objection I: there can be creation without conservation; therefore creation and conservation are not one and the same respect and relation. The antecedent is urged: something can be created and not conserved, as in an instantaneous thing; therefore since creation can be separated from conservation, it follows that they are not identified with each other. I respond by distinguishing the antecedent: if creation and conservation are taken for the relation of dependence of the creature upon the creating and conserving God, I deny it; if conservation is taken for the relation toward the non-being that mediately precedes, then it is distinct from creation, and creation can exist without it, as I made clear in the preceding note.

Objection II: no thing presupposes itself, otherwise it would both be and not be at the same time — it would be, because it is presupposed to exist; it would not be, because it would come to be afterwards. But conservation presupposes creation: for in order that something may be conserved, it must first have been created; therefore creation and conservation are not the same respect. The objection is to be met by the same distinction with which the preceding objection was resolved and dissolved. For conservation formally taken — as the respect of reason toward the non-being that mediately precedes — does pre-require and presuppose creation; but not so if it is taken for the dependence of

the created thing, which is entirely the same as the dependence of the conserved thing.

Objection III: creation is the reception of being by a thing from nothing, and no thing receives the being that it already has; for (6. *Phys. T. 7*) it is impossible that someone go to Thebes and be at Thebes at the same time; and thus it is impossible that something receive being through creation and again receive being through conservation. This would happen if conservation were the same relation as creation. All the more so since conservation of some effect can exist without its production, just as a figure impressed in wax is conserved after it has been impressed by the seal, even if the seal is broken; therefore conservation can exist without creation, and thus they do not bear the same respect. These and similar objections, which (*Aur. cit.*) accumulates abundantly and acutely, are all resolved by the same distinction as the preceding ones.

Article VII: Whether Through Creation Some Real Relation Accrues to God

(*Ockham 1. d. 30. q. 5*), (*Gabriel*), and the other Nominalists there assert that God's relation to the creature is a real relation; against them all the Realists protest: (*Scot. 1. d. 30. q. 2*), (*Rich. cit. q. 4*), (*S. Bon. q. 1*), (*Mayr. q. 2*), (*Viger.*), (*Orbel.*), and (*Vorrilong. eo in loco*), who deny that any relation — whether eternal or temporal, potential or actual — accrues to God through creation.

Note first from (*Scot. 1. d. 31. q. 1. §. Ad q. A.*) that a real relation requires three things. First: the foundation and terminus must be real; therefore there is no real relation of non-being to non-being, nor even of being to non-being. Second: between the foundation and the terminus there must be a real distinction; for this reason there is no real relation of the same thing to itself (5. *Met. T. 20*). Third: the relation must arise from the nature of the extremes, without any mind thinking of it; for if it is made by the work of a collative power, it will be a relation of reason, not a real one.

Note second that certain things are said of God in time not because something newly accrues to him, but because they signify and connote what occurs in time; thus God is called Creator and Governor because he creates and governs creatures that are made and endure in time, as the (*Seraphic Doctor passu praealleg.*) intimates, and after him (*Subtilis 4. d. 13. q. 1. §. Ad argumenta R.*), saying that "to create signifies the relation of passion and connotes an essential divine act that is intrinsic — not absolutely, but as it regards the creature"; and certain things belong to God by extrinsic denomination, just as a work is called human not because something of humanity is in it, but because it was made by a man; similarly urine is called healthy not because health is formally in it, but because it indicates health, which is formally in man. God is likewise denominated creating from passive creation, which exists formally in the creature, as (*Scot. 1. cit. §. Respondeo sub G.*) assents: "God is called Creator not because the relation of

creation is formally in him, but because he terminates the relation of passive creation, which is formally in the creature; and because he terminates the relation of the subjection of the creature, he is called Lord." Hence (*May. cit. q. 1*) notes that four predicates belong to God from time: one on account of creation, whereby he is called agent and creator; another on account of likeness, for the creature is like God, especially man, who is said to be made in the image and likeness of God (*Gen. 1*); a third on account of inequality, for God is said to be greater and more perfect than the creature; and a fourth with respect to distinction, whereby God is said to be distinct from the creature.

First assertion: God is not referred to creatures by a relation of reason. This is defended by (*Doct. 1. d. 20. q. 2. §. Respondeo. H.*) and in (*Rep. ibid.*). It is proved first: setting aside every intellect and abstracting from any relation of reason, God is still called Creator, because by his will — which is his omnipotence — he founded the creature; therefore God does not acquire this denomination through a relation of reason; for when the cause is posited in act, its effect is posited in act and the denomination of the cause from that effect follows. Since, therefore, God creates the creature by his will, he is denominated Creator through this creation, setting aside any intellect and relation of reason. Second: if, per impossibile, God were devoid of intellect — as some appeared to think who believed God to be the sun — he would have no relation of reason, and yet he would still be Creator, Governor, and Lord; therefore these denominations are not derived from a relation of reason. Third: a relation is not terminated toward a relative but toward an absolute, as (*Scot. cit.*) proves and as I showed at length in (*Log. lib. 3. q. de relatione*); therefore on the part of God, who is the terminus of the creature's relation, no relation of reason arises. Furthermore, the relation of reason would be either ancient and eternal, or new and temporal. Not the first, because the creature to which it is referred is not eternal; nor the second, because there would be no transition from contradictory to contradictory without change, and God is immutable; therefore in time he cannot in himself receive the aforesaid relation of reason. Nor is it necessary on the part of a created intellect, since, even if no created intellect existed to cause a relation of reason, if God were to create a stone or another creature, he would aptly be called Creator; therefore no relation of reason in God is to be admitted, through which he is called Creator.

Second assertion: there is no real relation of God to creatures, whether eternal or temporal. So (*Scot. passu praealleg. H.*), and as regards both parts (*Aug. 12. Civit. cap. 15*) does not venture to decide. The first part is urged first: a real relation does not arise except when both extremes are posited — that is, foundation and terminus, since it is the disposition of extremes to each other; but from eternity there is no terminus of the relation of God to creatures, since from eternity no creature exists, as is evident from (*1. q. huius lib. art. 2*). Therefore no relation of God to creatures exists. Second: relatives are simultaneous by nature and by understanding, for they mutually posit and mutually destroy each other, as

(*Arist. C. de ad aliquid*) well pursues; but from eternity no creature was founded, as faith teaches; therefore no relation of Creator to creature is to be conceded. You will say: God is creative and the creature is creatable from eternity, as I proved in (*art. 3. prima q. istius lib.*); therefore the relation of God to creatures has the property of a relation, namely, to be simultaneous by nature and by understanding. I say indeed that God is creative from eternity — that is, has the active power of creating from eternity — and the creature had the passive power by which it could have been created from eternity; but this does not introduce a real relation, either in God or in the creature, since the creature did not exist from eternity, and an accidental and adventitious relation is impossible to God. The second part is shown first from (*Aug. 5. Trin. c.*) as also (*Mag. cit.*), where our assertion is explained with this comparison: just as a coin constitutes a price without any real entity being added to it, so God creates the creature with no relation accruing to him. And (*ibid.*): "Nothing, neither absolute nor relative, accrues to God in time." Second, from the supreme simplicity, necessity, and infinity of God, which admit of no addition of a new real entity; otherwise God would be composite, contingent, and finite — as someone who would be composed with the relation accruing to him, which is contingent and limited. Third: a relation of the third mode is not mutual, as is clear from (*5. Met. T. 20*); but the relation of creation is of the third mode and is not mutual, just as the relation of the knowable to knowledge; therefore on the part of God, who is infinite, no real relation to the creature arises. Moreover, such a relation would be either substance or accident — not the first, because substance is toward itself, whereas a relation is toward another; nor the second, on account of its potentiality and inherence, which bespeak imperfection. Therefore no real relation is to be placed in God on account of the creation of things. Hence (*Magist. passu memorato*) rightly concludes: "The appellation by which a creature is said relatively to the Creator is relative and notes a relation that is in the creature itself; but the appellation by which the Creator is said relatively to the creature is indeed relative, but notes no relation that is in the Creator."

Objection I against the first part of the second assertion: what is attributed to God is eternal, as is clear from goodness, infinity, and the rest that are predicated of God and are eternal; but the relations of Creator, Governor, and Lord are attributed to God and said of him; therefore they are eternal and belong to him from eternity. I distinguish the major: through real identity, I concede; through termination, I deny. For God is said by us to be loved — not from eternity but in time, because we exist in time. So the aforesaid relations are said of God in time because creatures are in time, whose relations God himself terminates. Or, the major is true of predicates and attributes that are internal, but not of those that are external, such as Creator, Conserver, and Lord. You will press: the creature has essential and quidditative being from eternity, about which propositions of eternal truth are given, since it is necessary being; therefore the aforesaid predicates belong to God from eternity. I say that this is

not being simply but qualified, potential and ideal being, from which no real relation arises whose terminus is God, because neither it nor its foundation exists.

Objection II against the second part of the same assertion: the relations of active and passive power, according to (*5. Met. T. 20*), are real and mutual; but the relations of Creator, Conserver, and Lord are relations founded upon active and passive power; therefore they are mutual and real, both on the part of the creature and on the part of God. The answer is that the major applies to relations founded upon the power of a finite and limited agent and patient, but not to relations founded upon the power of an infinite and unlimited agent, such as the relations mentioned. You will press: the divine relations of begetter and begotten are real on the part of both extremes; and likewise the relations of equality and likeness among the divine persons; therefore the same must be said of the relations mentioned, which are relations of producing and produced, efficient and effect, inequality and likeness. The antecedent is conceded; the consequence is denied. The reason for the disparity is that in the former, both extremes are supremely necessary and infinite; in the latter, however, one extreme is contingent and finite.

Objection III: relations of disproportion and those that are opposed exist in distinct and opposed extremes — as paternity in the father and filiation in the son; but the aforementioned relations are of disproportion and are opposed; therefore God cannot be denominated Creator from the relation that is in the creature, nor Lord from the relation of subjection that is in the servant. The answer is that this applies to relations of the first and second mode, but not of the third mode — especially when their terminus is supremely simple, necessary, and infinite, as is the case in these relations.

You will press: form denominates the thing in which it is, as is clear from whiteness, which denominates the wall white in which it inheres; therefore since God is denominated by these relations, it is rightly inferred that they exist formally in him. I say that this is valid of intrinsic denomination, not of extrinsic and terminative denomination, by which God is thus denominated. Therefore God receives no relative form in himself, nor undergoes any change, but that form is in the created work, as (*Aug. 5. Trin. cap. 15*) rightly teaches and expresses in these words: "So also, when he is said to be angry with the wicked and at peace with the good, it is they who are changed, not he — just as light is harsh to weak eyes and gentle to strong ones, through their change and not through its own."

Question III

On the Fabric of the World

Article I: What the World Is

Although investigation and scrutiny of the things contained in the World is considered by (*Ecclus. 1*) to be vain labor and a troublesome occupation, nevertheless its investigation and knowledge is intrinsically good, since it is from God, from whom all good proceeds — though it is accounted incidentally evil insofar as it is accompanied by excessive study and great affliction of soul, and by the removal of piety and prayer to God, as (*Lyranus passu nunc memorato*) interprets.

There are some who hold that the World is one composite of matter and form. Others, like Plato and his followers — according to (*Aug. 10. Civit. cap. 29*) — to whom the same (*Aug. 1. de consensu Evangelistarum, cap. 23*) does not dare to object but appears to be undecided — hold that the World is a great animal. The common opinion, however, is defended by the rest of the authors cited below, who teach that the World is one by a unity of order.

Note first that "world" admits of many meanings. First, it is taken for everything that falls under the concave surface of the lunar sphere — in this sense (*Arist. 1. Meteor. cap. 3*) says: "this world here must continually be subject to the superior revolutions." Second, for corporeal creatures, both celestial and sublunar — in this sense the author of the sphere and his interpreters divide the world into superior and inferior. Third, for the inhabitants and dwellers of the world — in this sense (*Alph. 10. adversus haereses, verbo Mundus*) accepts it, following (*Aug. tract. 3 in Ioan.*): "The world is evil because evil men are the inhabitants of the world, just as a bad house is bad not because of its walls but because of those who dwell in it." And (*ibid. tract. 4*) it is frequently used for a wicked man, as one may see in the same (*Aug. 6. contra Julianum, cap. 1*) and (*in Psal. 34, conc. 1*): "In sinners the world is said, and in those who love the world, of whom it is said in (*Joan. 1*): 'The world did not know him,' and (*1 Joan. 1*): 'The whole world is placed in wickedness.'" And the Apostle expresses it in (*Eph. 7*): "The rulers of the darkness of this world — the rulers of the world I say, of these darknesses." And before him Christ the Lord in (*Joan. 7*): "The world cannot hate you, but me it hates, because I bear witness of it that its works are evil." Fourth, for the totality of all created things, both material and spiritual — in this sense God is said to have created the world, and it is said to have been made through him; and in this sense the philosophers discourse of the world in the present context.

Note second that various descriptions of the world are brought forward by authors, which do not appear to differ much from one another. The first is this: the World is an ordered collection of the heavens, elements, and the rest of creatures contained in them. This is perhaps what (*Aug. in Psal. proxime cit.*) had in view when he adds: "The world is said to be this fabric which we see." The second: the World is the perfect and complete gathering and ornament of all things. The third: the World is the ordering and distribution of bodies preserved by God and through God. Furthermore, order is defined by (*Aug. 19. Civit. cap. 13*) as the disposition of equals and unequals, assigning to each its proper place.

First assertion: the World is not one composite of matter and form. This is presupposed by (*Doct. in com. 12. Met. T. 52*) and (*tract. de 1. principio, c. 3*). It is proved first: if the world were one composite of matter and form, all things in it would be of the same species, because they would participate the same form and the same matter of the world; but that many things are diverse in genus and species no one denies; therefore the world is not something one assembled from matter and form. Second: what shares the same form and matter has the same operations, because form is the principle of operations; but we experience in the universe diverse operations not only in number and species but also in genus — as is evident from stones, herbs, trees, brutes, and men; therefore the world is not something one coalesced from matter and form.

Second assertion: nor is the world a great animal. This is also presupposed by (*Doct. ubi supra*); and the opposite view is retracted by (*Aug. 1. retract. cap. 11*). It is urged first: every animal possesses at least the sense of touch (*3. anima Tit. 66*); but the world does not have the sense of touch, as is plain from water, air, stone, metal, and similar things devoid of touch. Therefore the world is not an animal. Second: every animal is either rational or irrational; but the world is neither; therefore it is not an animal. The major is known and conceded by all. The minor is shown: it is not irrational, otherwise it would be a brute — but the Platonists reject this, for (*Aug. 10. Civit. c. 29*) reports, on the authority of Plato in the *Timaeus*, that they believe the world to be the most blessed and eternal animal. Nor is it rational — otherwise it would be a man, and therefore capable of grace, merit, sin, beatitude, damnation, and the like, which appear most absurd. The world must therefore be denied to be an animal. This is plainly demonstrated by the determinate members and specific organs by which vital and animal operations are performed in an animal, as (*Arist. 1. Phys. Tit. 36*) signifies and (*August. l. de beata vita*) assents, which cannot be discerned in the universe.

Third assertion: the World is one by a unity of order. So (*Scot. cit.*) and (*1. dist. 30. quaest. 2. sub Q.*) and (*Quol. 19. §. De secundo F.*) and (*2. dist. 1. quest. 4. §. Et quia ante C.*), preceded by (*Arist. 12. Met. Tit. 52*); and (*Pythagoras*) taught it, according to (*Plut. 2. de dogmatibus Philosophorum*), and (*Aug. quaest. 2. veteris et novi testamenti*) touched upon it with these words: "Substances being set apart from one another, a joining being made is called World." It is proved first: the world is defined as an ordered collection of created things, as is clear from the second note; but a collection means nothing other than the order of things toward one another pointing to one first; therefore the world is one by a unity of order. Second: one must philosophize about the world just as about an army or a kingdom, as (*the Philosopher proxime adductus*) rightly pursues; but an army is one by a unity of order — namely, of soldiers toward one leader — and a kingdom is likewise one by a unity of order — that is, of subjects toward one king; therefore the world too is established as one by a unity of order of all creatures toward one God, Creator, Governor, and their ultimate end.

Objection I against the first assertion: what shares the same matter certainly has the same form; but the world possesses the same matter, since there is only one matter in species for celestial and terrestrial things; therefore it consists of one form. But that which consists of one matter and one form is one composite; since therefore the world is of this kind, it plainly follows that it is one assembled from matter and form. The major is to be denied, since the unity of a composite is derived not from the unity of matter but from the unity of form; but since in the world there are many forms, there must also be many composites.

Objection II: what is better and more perfect is to be attributed to the world, because the world is the work of God, whose every work is perfect; but it is better and more perfect for the world to be assembled from matter and form than to be one by a unity of order, because the unity of composition is greater than the unity of order; therefore, etc. The answer is that the major holds provided that the thing is capable of such perfection; but the world is not capable of the unity of composition, but only of the unity of order. Hence someone would ineptly attribute rationality to a brute, of which it is incapable. Thus, in a similar case, (*Scot. 4. dist. 49. quaest. 7. §. Ad 1. ante D.*) responds, saying that joy is not of the essence of beatitude because the essence of beatitude strictly taken is not capable of it, just as wisdom does not enter into the essence of man.

Objection III: the whole is nobler and more perfect than its parts, as I said in (*q. de toto*); but some parts of the world are alive with animal life, as is plainly seen; therefore it must not be denied that the world is an animal — all the more because God seems to be the soul of the World, as is intimated in (*1 Reg. 2*): "I will raise me up a faithful priest, who shall do according to what is in my heart and my soul"; if, therefore, God has a heart and soul, certainly his body and matter can be nothing other than the world; and so the soul of the world is God. I distinguish the major: of the whole by a totality of composition, I concede; of the whole by a totality of order, such as the world, I deny. To the other point added, (*Aug. 14. Civit.*) responds: "We do not believe that God has a soul, since he is the founder of the soul; but this is said tropically and not properly, just as he is said to have hands, feet, and other members of the body."

First query: whether there is only one world in number? (*Arist. 1. Celi 8*) answers affirmatively, and this can be urged from Scripture: (*Joan. 1*): "The world was made by him"; and (*eiusdem 7*): "The world cannot hate you"; and (*Rom. 5*): "By one man sin entered into this world"; and (*Marci ult.*): "Go into the world, preach the Gospel to every creature." Thus the sacred text speaks of the world in the singular, to show that there is only one world in number. And that this is fitting is shown by (*Alens. 1. p. quaest. 15. m. 1*), saying: "Just as God is one and the first cause is one, likewise the world is one, which is in the eyes of all his great work." (*August. serm. 8. de sanctis*) adds his support with these words: "Common nature

testifies to one Lord, because there is one world." And (*quaest. 2. novi et veteris test.*) adds: "Therefore God, who is one, made one world, so as to teach that all things are from one."

Second query: whether the world is infinite? (*Arist. cit.*) answers negatively, and (*Aug. 11. Civit. 6*) confirms this. The reason is that an actually infinite is not possible, as I showed in the question on the infinite; furthermore, what is measured is finite and limited; but the world is measured by mathematicians in all its parts; therefore the world is finite.

Article II: Whether Several Worlds Can Be Founded

Among the philosophers, (*Arist. 8. Phys. c. 1*) and (*1. Cali, T. 103*) — who hold that the World was necessarily and naturally produced — maintain that several worlds are not possible. Those who do not appear to differ from them are (*Abailard*), (*Wyclif*), and (*Luther*), reported by (*Alphonsus 7. adversus haereses, ver. Futurum contingens*), who suspected that God cannot create more things than he has created, nor make things otherwise than he made them. The common and true opinion, however, is that maintained by (*Rich. 1. d. 44. q. 4*), (*Major ibid. q. 1*), (*S. Bon. q. 4*), (*Vulpes tom. 2. p. 1. disp. 42. q. 13*), (*Conimb. 1. Cali c. 9. q. 1. a. 2*), (*Ruv. q. 2*), and the rest there, who teach that several worlds are creatable by God.

Note that it is possible to understand the existence of several worlds in two ways — namely, simultaneously or successively; and then as concentric, sharing the same center, or eccentric, sharing different centers, or one being outside the other; and furthermore, differing only in number or also in species; and moreover, several finite or infinite ones.

Assertion: God can create several worlds simultaneously or successively, though finite and limited. (*Doct. 4. Rep. d. 50. q. 1*) supports this. It is proved first from (*Athan. oratione contra idola*), (*Ambr. 2. exam. c. 1*), and (*Ansel. 1. 1. cur Deus homo c. 1 and 2*), cited and received by (*Doct. ubi supra*), who affirm that by divine power many worlds can be founded. The University of Paris lends its support, decreeing the contrary opinion to be false and erroneous, as may be seen at the end of (*4. Magist. Sententiarum*) and at the beginning of (*1. S. Bonaventurae*), where the aforesaid error is recounted among the errors condemned by (*the Lord Stephen, Bishop of Paris*). Second: God is now of the same power as then before the world was founded, since he is the same and his years do not fail; but when he created the world, he existed of infinite power, which is not exhausted in the construction of the world; therefore with his power he can achieve other producible worlds. Third: there is no repugnance in other worlds being produced, neither on God's part, who is of unlimited and infinite power, nor on the part of the worlds, which are producible and creatable. For just as this world before its construction was producible, so another and another is producible, since no stronger reason appears for this one than for others. Furthermore, although there is only one sun in number and one moon in number, yet another

sun and another moon is creatable; likewise, although only one world in number has been founded, there is no repugnance in other worlds being produced by God. Therefore several worlds are creatable by God, differing in number if the creatures placed in them differ in number, or in species if the creatures are specifically distinct. They cannot, however, be actually infinite, since from what was said in the question on the infinite, no actually infinite thing — whether in magnitude, multitude, or intensity — is possible, whatever (*Vulpes praealleg.*) protests.

Objection I: there is only one archetypal world, and one idea of it, after the likeness of which this world was fashioned and architected; therefore another world besides this one is not possible. The antecedent is known. The consequence is proved: nothing is makeable unless it has an idea in the divine mind, as is the common opinion and axiom of theologians. The answer is that the major is true of the world already founded, but not of other possible ones, of which there are in the divine mind as many ideas as there are worlds creatable and makeable.

Objection II: (*Arist. 1. Cali, c. 9. T. 95*) writes that there is one matter of the World, which in it, already made, has been completely used up and consumed; but if another world were possible, it could not be made without this matter, because another different from this is not creatable; therefore another world is not makeable either. The answer is that the major holds for Aristotle, who thinks God acts necessarily toward the outside and that he created all matter; but not for us, who assert that God acts freely toward the outside and can create another matter different from this one, according to the good pleasure of his will.

Objection III: nothing disordered or preposterous can be effected by God, since he is the most orderly and wisest craftsman; but if God were able to found another world, he would make certain disordered and ill-disposed things — there would be diverse places in species for heavy and light things, several first movers and first causes, and other things that involve repugnance. The major is conceded; the minor is denied. In response to its proof, I say that, given the hypothesis, there would be distinct places in species for heavy and light things, and each world would have its own proper center and place for heavy and light things. To what is further added, I say that for each world there would be constituted a particular first mover in its own order, just as in this world there is a first angel moving immediately the first heaven; but there would be one supreme mover and one first cause from itself and independent, and one monarch of all. This can be explained by the analogy of a kingdom, in which there are several universities, each of which has its own rector appointed to it; yet there is one primary head of such universities, just as there is one King and one Lord of all who dwell in the kingdom.

Article III: Whether the World Is Perfect

Many things about the beauty, order, and perfection of the universe are written by (*Alensis* 2. p. q. 16, 17, 18), (*Franciscus Georg. in opere de harmonia mundi*), (*Guillelmus Parisiensis in volumine de universo*), and very many others. The common and true doctrine of all doctors is that the World is perfect. For its explanation:

Note that something can be said to be perfect in two ways. In one way, simply and beyond all category — that to which no perfection is lacking and to which no perfection can be added or removed — in this way God alone is perfect, as (*Doct. 4. d. 49. q. 14. §. Ad 1. rationem M.*) observes; and this can be drawn from Sacred Scripture: (*Matt. 19*): "One is good, God"; and (*Marci 10*): "No one is good except one, God" — that is, perfect. In another way, in a qualified sense — that is, in its own genus — in which sense that is called perfect which has everything required for its being. And since being is twofold — substantial and accidental — so too there is a twofold perfection: one according to substantial being, to which no substance is lacking that pertains to its nature, as in the case of a man who has everything required for his substantial and essential being; and one according to accidental being, which is called perfect when it participates all the perfections required for its accidental being — as that person is called a perfect philosopher who possesses everything pertaining to perfect philosophy.

Assertion: the World is perfect. This is presupposed by (*Doct. 1. d. 44. q. un.*), where he inquires whether God can produce things better and more perfect than he made them, and answers affirmatively. If, therefore, God can found a more perfect world, it is presupposed that the world already made by him is perfect. The assertion is proved first from Scripture: (*Gen. 1*): "God saw all the things that he had made, and they were very good" — that is, perfect, as some interpret that passage; and this interpretation is drawn from (*c. 2 of the same book*), where it is read: "So the heavens and the earth were finished, and all the furniture of them. And on the seventh day God ended his work which he had made." For (*Bercorius in parte tertia sui rept.*) notes that "perfect" means the same as "completed," and "to perfect" means the same as "to complete." If, therefore, God completed his work which is the world, he certainly perfected it, and therefore the world is perfect. And (*Deuteronom. 32*): "The works of God are perfect." The world, however, is the work of God, as is narrated in the place cited; therefore it is perfect. (*Aug. 11. Civit. c. 21*), citing Plato, says that God was lifted up with joy at the perfection of the totality of the world. And (*quaest. 223*): "All things are perfect in their kind; one is said to be more perfect than another in a relative sense, as a man is more perfect than a brute. But God is perfect in all things, because he is, as it were, the fountain and origin of all." The same he writes in (*1. de perfectione iustitiae, contra Caelest.*). And (*Boeth. 3. de consolatione, metro 5*) adds his support. (*Arist.*), cited and received by (*Scot. Quol. 19. art. 2. F.*), who in (*12. Met. T. 52*) places the goodness and perfection of the universe in the order that the parts have toward one another and toward the one first being and first cause. Second, from (*5. Met. 21*): "each thing is perfect and every substance is

perfect when, according to the species of its proper virtue, no particle of its natural magnitude is lacking." (*Scot.*) adds there (*in exp. c. 6*) that that which lacks nothing is perfect, and calls a circular line perfect but not a straight line, because something can be added to the latter. The same he teaches in (*Theorem 23*): "that is said to be perfect of which there is nothing outside to be taken." But the world is round and of circular figure, as is seen in the sphere, and nothing is lacking to it, as will be made plain in the resolution of the objections. Furthermore, a perfect craftsman produces a perfect work, as is clear in the case of an outstanding and distinguished painter or sculptor; but God is the most perfect craftsman, from whom every art and every good and perfect work proceeds. Again, the world is, as it were, ornament and beauty, as I observed at the beginning of this book; and according to (*Dionysius 4. de divinis nominibus*), the beautiful means the same as the perfect. And this is indicated by so many genera, species, and individuals of things with which it is adorned and enriched, so that he may rightly be called blind who does not contemplate its elegance, beauty, and perfection.

Objection I: in the World there are many foul, deformed, and evil things — monsters, crimes, iniquities, injustices, calumnies, and outrages — which show that the world is not in the least perfect. Hence (*Hierem. 12*) cries out: "the way of the wicked prospers, all who transgress and act unjustly are well off." The answer is that many things which seem to us evil and very deformed greatly assist the beauty and perfection of the universe, according to the adage: "opposites placed side by side shine out more clearly." For God established opposites, as (*Ecclus. c. 3*) notes: "Against evil is good, and against death is life; so also against the righteous man is the sinner. So look upon all the works of the most high; two and two, and one against one." Moreover, a fair day is indeed beautiful, but appears more beautiful in contrast with night and darkness; likewise, the color white seems more beautiful in contrast with black, as (*Aug. 11. Civit. cap. 23*) expresses, saying: "Just as a painting in which black color is placed in its proper place, so the totality of things, if one could behold it, even in sinners, is beautiful — although when they are considered in themselves, their deformity mars them." The same he has in (*1. 83. q. 9. q. 79*) and in (*Ench. c. 11*): "Evil, well ordered and placed in its proper position, commends good more eminently so that good may please more and be more praiseworthy when compared with evils." All the more so because all those things happen so that God may elicit good from them. For God permits man to fall into sin so that on the occasion of it he may accomplish a good work — namely, conversion, repentance, and humility. Hence (*Psal. 112*) David says: "It is good for me that you humiliated me." And of Adam's sin the Church sings: "O happy fault, which merited to have so great and such a Redeemer." (*Aug. 1. 2. de peccato Orig. contra Pelagium, cap. 34*) adds: "God certainly, in the evil work of men, himself does his own good work." And (*11. de gen. ad litt. c. 21*): "God draws good from evil." Moreover, in many things the judgment of God lies hidden, which hardly any man can penetrate. Hence

(*Eccles.* 5) warns: "If you see the oppressions of the poor and violent judgments and the subversion of justice in a province, do not be surprised at this matter, because there is one that is higher on account of this." (*Aug. in annot. Iob. cap. 11*) writes therefore: "You ought not to blame God, whose works you do not comprehend." The same he commits to writing in (*libro 4. de Symb. ad Cathecumenos cap. 2*).

Objection II: in the world there are lacking many species of things that are possible and creatable by God; and there are certain things in excess, like so many pebbles, so many grains of sand, and other forms of this kind; therefore the world is not perfect. The answer is that producible species of things do not pertain to the integrity and perfection of the World, since it is perfect by reason of what it actually has. Nor is there anything superfluous in it; for all those things which appear superfluous proclaim the power and magnificence of God. Although to the ignorant and foolish they may appear superfluous, they are not so to the knowing and wise — as (*Aug. in Psal. 148*) says: "he who does not know the art of some craftsman, looking at so many instruments in his workshop, judges them to be useless and superfluous; so also, he who does not know the order and disposition of the universe, judges the things just mentioned to be superfluous — though all things are rightly disposed and ordered by God the supreme craftsman of all," as (*Aug. 1. de natura boni, contra Manich. c. 8*) splendidly shows: "They are so ordered that the weaker yield to the stronger, the feebler to the more powerful, and the less potent to the more potent; and so the terrestrial harmonizes with the celestial, as what is subject to what is more excellent. Moreover, as transient things succeed one another there is a temporal beauty of a kind proper to their kind, so that neither those things which die, nor those which were and then cease to be, mar or disturb the order, form, and beauty of the total creation — just as a well-composed speech is altogether beautiful, even if in it syllables and all sounds pass away as it were by being born and dying." And (*3. de libero arb. 23*): "No leaf of a tree is created superfluously." And if some things seem useless, noxious, and superfluous to you, consult the same holy Doctor, who in (*1. de genesi, contra Manich. 16*) says and concludes: "Use therefore what is useful, avoid what is pernicious, leave aside what is superfluous."

Objection III: if the world were perfect, it would be so principally because its parts are Angels and men; but Angels are minds above the world, and men are inhabitants and the end of the world; therefore the world is not perfect. The major is conceded; the minor is denied. For Angels are called minds above the world when the world is taken for the collection of sublunar things only; but not so if it is taken for the totality of all created things. For in this sense Angels are parts of the world, since they are counted among creatures. Men too are parts of the world and its end, because it is not unfitting in a whole for one part to be ordered toward another — as is clear from the parts of the human body, of which certain ones are ordered toward others, while all together complete the

whole. Therefore man is a part of the world and its inhabitant, and is called its end because all things were founded for his sake.

Article IV: Whether God Can Make the World Better and More Perfect

(*Richardus 1. d. 44. q. 1. art. 1*), following (*Hugo Vict.*), and (*Conimb. 1. Cali cap. 9. q. 2*), report that some hold the world to have been so made by God that it cannot be made better and more perfect. Those who appear to subscribe to this view are those who hold that God always does what is best; (*Granadus*) is cited by (*Pont. disp. 54. q. 2*) and is there refuted by him and by (*Lugo disp. 2. de Incarn. sect. 1*). The common opinion of the scholastics, however, at (*1. d. 44*), is that of (*Scot. q. un.*), (*Bon. q. 1. 2. 3*), (*Aur.*), (*Ockham ibid.*), and (*Alensis 1. p. q. 21. art. 7. m. 3*), who teach that God can make the world more perfect and better.

Note first that this difficulty can be raised both from the side of the maker and from the side of the work made or to be made; and likewise concerning this founded world, or another possible one differing from it in number or species; and again, with respect to specific or individual being, substantial or accidental. Furthermore, since the world is established as one by a unity of order, the question is whether such order and disposition can emerge more harmonious and more beautiful.

Note second that in a free and voluntary agent a twofold power is distinguished: one absolute, which is bound by no law; another ordained, by which the agent operates according to prescribed and fixed laws. In God, however, the absolute power is that which regards everything possible and involves no contradiction; but the ordained power is that by which God does whatever he from eternity decreed and ordained to be done and performed in time, as I made plain in the question on the infinite, (*art. 2*).

First assertion: God does not always do what is better and more perfect. This is deduced from (*Doct. 3. d. 13. quaest. 2. §. Ad argumenta istarum qq. sub. 1. in solutione 2.*), where he says that in the order of grace there is a supreme and most perfect grace in Christ, but not in the order of nature, since some nature can be created more perfect and more excellent. Furthermore, in the same place (*distinctione 7. quaest. 3*) he writes that if Adam had not sinned, the divine Word would have assumed human flesh; but it was better that Adam had remained in the state of innocence, since this is more excellent and more worthy than the state of the fallen; but God, if he had willed efficaciously, the state of innocence would have persisted; nevertheless the state of sin persists, though it is inferior and worse. This can also be urged from those words of Christ the Lord in (*Matt. 26*): "It were better for him if that man had not been born." But God could have prevented the birth of that man — namely, Judas — if it had pleased him, and did not prevent it; therefore God does not always furnish what is better. Furthermore (*Marci 14*): "Abba, Father, all things are possible to you; remove this chalice from

me; but not what I will." But the passion of Christ was the highest good, though Christ himself desired and willed to be freed from it. Furthermore, God is free in every work toward the outside, according to (*Psal. 134*): "All things whatsoever he willed, he made in heaven and on earth"; but if he could only produce the best thing, he would be compelled and necessitated to its production alone, which conflicts with the testimony of Scripture just adduced. You will say: the Father and the Son spirate the Holy Spirit necessarily, though also freely, as (*Scot. 1. d. 2. quaest. 7*) and (*Quol. ib.*) teach; therefore it is not surprising if God necessarily willed always to produce what is best and most eminent. I say that there is a disparity, since the Holy Spirit is the supreme and infinite good, from whose love and production God the Father and the Son do not withdraw; but whatever is created is a finite and limited good, and therefore in its production he acts freely and contingently, nor does he receive anything of perfection from the created work, nor does he need it, as (*David, Psal. 15*) attests: "You have no need of my goods." Therefore he is not constrained to always act in the best possible way.

Second assertion: the World can be made better and more excellent, not only essentially but also accidentally. The assertion is twofold, and (*Doct. in 1. passu alleg.*) maintains it. The first part is proved: God can found other possible species of things in the world, by which the world itself would be made essentially more perfect, since the power of God is infinite and inexhaustible. Furthermore, the world is essentially perfect through the creatures that it essentially contains — which are essentially perfect and essentially distant from one another, as I observed above; since, therefore, God can found other creatures that differ in species, it is clearly deduced that he can make the world itself essentially more perfect. Moreover, the divine Word can hypostatically unite to itself another intellectual nature, such as an Angelic one; indeed, the other divine Persons can do the same, as I said in (*tract. de Incar.*). The second part is proved: God can create another supreme grace equal to the grace of Christ and confer it on Peter or another man, and grant him the highest enjoyment, as (*Doct. in 3. loco cit.*) teaches. Likewise, other qualities can be intensified, since they admit of more and less; and through these the world would accidentally become more perfect. For more blessed Angels could be created, more learned men, faster horses, more beautiful birds, and other things of this kind by which the world would appear more illustrious. (*Scot. in 1. Rep. d. 44. quaest. 2*) adds that celestial bodies could be made more clear, more limpid, more subtle, and capable of receiving foreign impressions that are not corruptive but perfective. And this will one day come to pass, as (*Ela. 30*) prophesies: "And the light of the moon shall be as the light of the sun, and the light of the sun shall be sevenfold, as the light of seven days." (*Ioan.*) predicts in (*Apoc. 21*): "I saw a new heaven and a new earth." (*Hugo Vict. 1. de sacr. parte 3. c. ult.*) lends his support. And this can be confirmed from (*3. Top. 32*): things that are less mixed with their contraries are more such — as the whitest is that which is most unmixed with black; similarly better is what is

less mixed with evil. But God can remove from the world every evil and every harm, as would have occurred in the state of innocence and as obtains in the kingdom of the Blessed.

Third assertion: with respect to the order and disposition of things, the world can be made better and more excellent. This is deduced from (*Scot. praecit.*) and is proved: the elements, which are now confused and intermixed — and notably the earth, which in many people's opinion is elevated above the sea — can be depressed and returned to the lowest place, which is proper to it, and purified and distinguished; therefore with respect to order, the world can be perfected further. Furthermore, a better and more illustrious order is sought from better and nobler creatures more aptly disposed toward one another and more rightly ordered; but God, from what has been said, can found nobler and more excellent creatures and dispose and order them better, since this involves no repugnance; therefore the world with respect to the order of its parts can become better and more excellent.

Objection I against the first assertion: from the best there can come forth only the best, according to (*Plato and Dionysius S. cit. ab Aur. ubi supra*); but God is the best and greatest craftsman, since he is infinite and immense; therefore from him only the best is produced. The same (*Damasc. 2. fidei c. 29*) teaches. And it is confirmed from (*Aug. 3. contra Maximinum c. 7*): "if the Father could beget a son equal to himself and did not beget him, he would be envious"; therefore likewise if God could make the world better and more perfect and did not, he would be charged with envy, which is far from God. I distinguish the major: of a necessary agent bound to act in this way, I concede; of a voluntary and free agent bound by no law, I deny. But God is a free agent and debtor to no one; therefore it is within his power to produce good, better, and best. The Apostle signifying this in (*Rom. 9*) says: "Does not the potter have authority over the clay, from the same mass to make one vessel for honor and another for dishonor?" The testimonies of the holy Fathers and the confirmation from Augustine are to be interpreted in the same way. For God the Father begets the Son necessarily and naturally, but produces creatures spontaneously and freely. You will say: nothing disordered, preposterous, or unjust can be effected by God, since he is the most orderly, prudent, and just agent; but if the world were made more beautiful and illustrious by him, it would be done contrary to the order established by him from eternity, contrary to the rules prescribed by him, and contrary to what nature requires and reason demands. I say that none of these things follow, since God is the Lord of all, his will is the first rule, and he is debtor to none; therefore that which he wills is ordered, just, and right, and what he does not will is neither good nor just. Therefore, while this holds true of ordained power, it does not hold of absolute power, which regards everything that involves no contradiction.

Objection II against the second assertion: what does not admit of more and less cannot be made better and more perfect; but the world does not admit of more and less with respect to the substances of which it consists, since it is a property of substance not to admit of more and less, as is clear from (1. *praedicam. c. de substantia*) and (8. *Met. cap. 1*); therefore it cannot be more perfected and adorned. The major is conceded; I distinguish the minor: in specific being, I concede; in individual being, I deny, as (*Antonius Andr.*) and (*Joan de Magistris*) note there. You will say: in the world there exists Christ the Lord, God and man, than whom nothing more perfect can be made; therefore the same must be said of the rest that have been made in the world by God. I concede the antecedent — and the same of the Sacrament of the Eucharist and of certain other things of which I made mention in the question on the infinite, (*art. ult.*) — but I deny the consequence, as is clear from the grace of the just and their enjoyment, which is not supreme like that of the Savior.

Objection III: there is a supreme creature — namely, the first Angel — and an infimum — namely, prime matter. Therefore God cannot create a world better or worse than the one produced. The antecedent is urged from (*Aug. 11. Conf. cap. 3*), where addressing God he says: "You made two things, O Lord: one near to you — that is, the Angel — and another near to nothing — that is, prime matter." I distinguish the antecedent: in fact, I concede; of what is possible, I deny. In this way (*Scot. in Rep. cit.*) is to be interpreted in expounding (*Augustine*) — not only in the passage cited but also in (1. *de quantitate animae, cap. 33*): "It has been made by the justice of God that not only all things exist, but also exist in such a way that they cannot be better." You will say: the world is one by order; but order is a relation, which is not intensified nor diminished; therefore neither can the world be perfected. I say the world can be made more perfect not precisely with respect to order, but with respect to the things that are ordered, which are comprehended in it.

Article V: Whether a Creature Can Create Anything as a Principal Cause

This doubt can be treated in two ways — namely, in fact and in possibility. Concerning the first: whether any creature has created anything? (*Avic. 9. Met. cap. 4*) holds that in the creation of things there is a golden chain, saying that the first intelligence created the second, the second the third, and so forth down to the last, which founded this entire mass of the world. (*Plato in the Timaeus*) lends his support — who, according to (*Aug. 12. Civit. cap. 26*), says that lesser gods — that is, Angels — were the founders of the bodies of animals; to this the (*Cerinthians*) subscribe, according to (*Aug. in catalogo haeresium, haeresi 8*), who hold that the world was made by Angels. But the true and common teaching is that no creature has created anything. Concerning the second: whether the principle and power of creating can be communicated to any creature? The scholastics contend on this. For (*Major 4. dist. 1. in fine q. 1*), (*Dur. 2. dist. 1. q. 4*),

(*Gabriel ibid. art. 3*), (*Arriaga disp. 11. Phys. Sect. 5. subsect. 2*), and (*Raco. tract. de causis in append. sect. 1. quaest. 2*) assert that the power of creating involves no repugnance for a creature. The more probable and common opinion is that of (*Scot. 4. q. 1. q. 1*), (*Th. 1. p. q. 45. art. 5*), (*Aur. 4. q. prooemial. art. 3*), (*Ockham 2. q. 7*), (*Molin. 1. p. q. 450 art. 5. disp. 1*), (*Suarez disp. 20. Met. sect. 2. and 12*), and others, who deny that a creature can participate the power of creating.

Note first from (*Scot. cit. §. Ad q. ergo. DD.*) that a principal cause is of two kinds: one independent and from itself, acting and producing the total effect without any concurrence of another cause of the same or a different order — in this way God alone is named and is the principal cause, because he alone is from himself, independent, and needs nothing for causing; the other dependent, which acts by its own proper and intrinsic power, yet requires another superior cause to cause together with it and concur in producing the effect — such is every secondary cause, which by its own power exerts influence on the effect; and in this it differs from an instrumental cause, which acts by the power of another — that is, the principal cause — in producing the effect, as I asserted in (*lib. 4. Phys. q. 5*).

Note second that a creature taken universally is either substance or accident; substance is divided into spiritual — which is either complete, like the Angel, or incomplete, like the rational soul — and material, which is either partial, like matter and form, or total, like the composite. Accident is either relative, arising from the positing of the extremes, like paternity; or absolute, which is subdivided into material — which is drawn out from the potency of the subject — and spiritual, which is produced by God, like grace. Further observe that substance is prior to any accident that is located in it, since the subject — such as substance — precedes everything that is received in it, such as accident. This (*Scot. cit. §. Ita ergo*) pursues at length and admirably.

First assertion: in fact no creature has created anything. This is deduced from (*Doct. ubi supra, §. Ad q. ergo*) and (*§. Ideo dici potest*), where he shows that the power of creating does not belong to the creature; therefore if creation is denied to a creature *de possibili*, then also *de facto*. For whoever denies someone the first act denies equally the second act, which proceeds from the first. It is proved first from Sacred Scripture: (*Gen. 1*): the creation of all things is attributed to God — "he said, and they were made; he commanded, and they were created." And afterwards it is added: "On the seventh day he rested from all the work which he had made." (*Ecclus. 18*): "He who lives forever created all things simultaneously." And (*Hebr. 3*): "He who created all things is God." Second, from the Lateran Council, *c. Firmiter, de summa Trin. et fide catholica*: "God from nothing founded each creature, spiritual and corporeal, angelic and mundane." The Apostles' Creed and the Nicene Creed are added: "Creator of heaven and earth," and "Maker of heaven and earth, of all things visible and invisible." And the First Council of Braga, (*capite 13*), establishing that the creation of all flesh is the work of God. Hence (*Scotus in Reportatis passu alleg.*) honestly confesses that he holds

the proposed assertion more by faith than by reason. (*Suarez cit.*) subscribes to this, and (*Alphonsus lib. 5. adversus haereses, verbo creatura*) attests that the contrary is condemned as heretical — against (*Arr. ubi supra*) who says that the Council does not speak of creation in the strict sense but broadly taken, for any kind of production, whether from nothing or from a pre-existing subject. Against this: the Lateran Council especially defines God to be the founder of corporeal and incorporeal creatures; if, therefore, God is the maker of both, as is narrated in (*Genesis primo*), it plainly follows that no creature has in fact touched creation in the proper sense according to faith — since creation broadly taken is also attributed to God alone. Hence in (*John first*) it is had: "all things were made by him, and without him was made nothing." And (*Apoc. 4*): "Because you created all things." Therefore it is indicated in the said places that God produced all things, both what is made from nothing and what is produced from a pre-existing subject. Afterwards, created things by the power communicated to them by God produce their own works, with the same God concurring with them — not from nothing, but from pre-existing matter. Third, from the holy Fathers: (*Aug. 1. de gen. contra Manich. c. 6*) and (*12. Civit. c. 24 and 25*) and (*1. de lib. arb. c. 1*) and at the end of (*c. 2*): "God created all things from nothing." (*Ansel. in Monol. c. 23*): "The supreme existence is only one, which alone is the Creator." And (*Damasc. 2. fidei, cap. 3*): "God alone is maker, provider, and container of all." The same write (*Athan. 1. contra Arrian.*), (*Hilar. 8. Trin.*), and others concordantly and unanimously. Therefore (*Aur. praemem.*) attests that he adheres to the proposed conclusion, against (*Arr. cit.*) who says that this opinion was not expressly handed down by the Fathers and that they spoke of creation that is independent and from itself. But their explicit meaning is sufficiently established from the words of the same Fathers cited above, especially since they were disputing against sectarians, notably the Arians who denied that the Word was God; against them they argued thus: the divine Word is the Creator of all things, just as the Father; therefore it is God just as the Father. For if it were a creature, as those heretics maintained, it would not be Creator, possessing the power of creating, since no creature enjoys the power of creating. Therefore, although the Son of God is not from himself but from the Father, and has creative power from the Father himself, on that account he is not considered not to be Creator; and therefore the aforesaid Fathers are not treating of creation that is from itself and independent, as (*Arr.*) supposes. Third: a created agent presupposes a subject upon which to act, as (*Scot. 7. Met. quaest. 11*) notes, and (*the Stagirite*) writes as a true and well-known axiom: "from nothing, nothing comes" (*1. Phys. Tit. 41 and elsewhere*). The reason is that a created agent is dependent in its operations upon matter; but creation is production from no pre-existing subject; therefore it belongs to no creature. Fifth: to whom repugnance toward the first act belongs, to the same repugnance toward the second act belongs too, because the second proceeds from the first, and when the principle is removed the thing based on the principle is removed too; but to a creature as instrumental cause the first act — that is, the power of creating — involves repugnance, since this is from itself

and independent, belonging to God alone; therefore a creature cannot be assumed by God as an instrument of creation. The minor will be shown in the next assertion, in which it will be proved that the principle of creating cannot be communicated to any creature; and consequently, if *de possibili* creation cannot belong to a creature, then neither *de facto*.

Second assertion: no creature — whether made or makeable — can create anything as a principal cause. Such is the common judgment of theologians, notably (*Scot. cit. in utroque opere Oxon. et Parisien.*). It is proved first from (*D. Aug. 3. Trin. cap. 8*): "No creature can be called the creator of any thing." And in the same place (*cap. 9*) and (*l. 9. de genesi ad lit. cap. 15*) and (*l. 2. q. q. super Exod. quaest. 11*). And (*Athan. passu alleg. in ant. assert.*): that a creature cannot be a creator is certain to all. Second: every creature made or makeable is either material or spiritual, corporeal or incorporeal, as I explained in (*Epitom. l. 1. q. 3. art. 4*). But neither can create anything. And indeed not the material — which is matter, form, or composite. Of matter it is plain, because it is passive and the subject of every form. But form, since it is drawn out from matter's potency, operates in the way it has being; but it has being through being drawn out; therefore it also acts dependently upon the subject from which it is drawn out. Therefore in being and in operating it depends on that same subject, and hence cannot create. The same must be established of the composite, which, since it consists of matter and form, clearly participates the same manner of acting as those two. For it is the total and adequate caused thing of both, which does not transcend the limits of the actions of the said causes; but these cannot reach to creation; therefore neither can it. Of the spiritual creature — which is the Angel or the rational soul — the same must be said. First, (*Aug. 9. de gen. ad lit. cap. 15*) teaches that "no Angel can create a nature, just as it cannot create itself." But the rational soul is of lower nature and power than the Angel; if, therefore, the latter cannot create, neither can the former. The reason is given: every spiritual creature acts by intellection and volition, which are accidents; but an accident by its own proper and intrinsic power cannot reach the production of substance, which is effected by creation. Therefore no creature — whether created or creatable — can create anything. This reason displeases (*Suarez disp. 20. Met. sect. 2. num. 19*) and (*Arr. cit.*), who say that intellection and volition can be pre-required and can concur toward creating something in the manner of a directing and applying cause; since an intellectual agent must preknow what is to be done through its cognition — as it operates for an end — and through its volition must apply its executive power, by which the work intended by it is produced. Therefore just as a man understands and wills generation, and the generative power generates, so there could be given an intellectual creature which, through prior intellection and volition, would create something through the power and virtue of creating communicated and infused in it by God. But this objection of Suarez does not enervate but corroborates the argument of Scotus, since it is expressly had in (*Scot. cit. §. secunda propositio*): "an intellectual agent does not produce

immediately through its nature and substance — otherwise in divine things there would be four persons, one produced from the fecundity of nature beyond the other three, which is false and heretical." In created things, moreover, if there were an executive power, it would be subordinated to the intellective and volitive powers and inferior to them, from which creation — which is the most excellent action — cannot proceed. But man generates man not through some power belonging to him through the rational soul, but through a natural material faculty, as irrational animals perform. Hence Angels — not participating that power — cannot generate other Angels similar to themselves.

Third: no creature made or makeable can be endowed with infinite power, for the power does not exceed the nature from which it proceeds; but every creature is finite and limited; therefore its virtue and power too is finite and limited. But the principle of creating is infinite, since it is entirely independent of another — that is, of a subject and matter, since it produces a thing from nothing; therefore it cannot be adapted to any creature. Moreover, the most excellent creature, to do something wonderful, achieves it by the application of natural active things to passive ones, as is read in (*Exod. 7*) concerning the serpents produced by the Magicians of Pharaoh, and as I taught in (*Lib. 3. Phys. quaest. 2. art. 2*). Furthermore, over so many spans of years from the beginning of the World until now, there has been found no creature that has produced anything from nothing — which is not a small sign that no creature can create anything, just as from the first construction of things no part of the heaven has been corrupted, which is a sign that the heaven itself is incorruptible, as I shall show in the next book.

Objection I against the first assertion: (*D. August. hom. 80 in Joan.*), and it is drawn up in (*Can. 1. quaest. 1. Detrahe*): "What is the great virtue of water, that it should touch the body and cleanse the heart?" But the heart is cleansed through grace, which is created by God in the soul upon receiving the sacrament of Baptism; therefore baptismal water creates grace, and thus a creature can create something. The answer is that the words of Augustine are not to be taken physically but morally — that is, by virtue of the pact by which God decreed to create grace in the one receiving the sacraments who places no obstacle. Therefore God physically creates grace, not water or any other creature. You will press: the Council of Florence, in the decree of Pope Eugene, setting forth the difference between the sacraments of the old law and the new, decrees that the sacraments of the latter cause grace, but not those of the former; but grace, according to (*Scot. 2. d. 34. §. iste q. A.*), is created; therefore a creature reaches creation. I say that the aforesaid Council and others define that the sacraments confer grace on those who receive them worthily; but concerning the manner in which they cause it, they do not determine, but leave it to be disputed among the scholastics, some of whom hold they cause grace physically, others morally.

Objection II: the same holy Doctor (*1. 83. q. 9. q. 78*) writes that artisans create nothing, because they act dependently upon matter; but Angels do not depend upon matter, since they are incorporeal and immaterial; therefore Angels can create something. The answer is that indeed to act dependently upon matter is one reason why artisans cannot create; but it is not the only reason — the more powerful reason is to be from another and dependent in being and operating. Therefore, although Angels are separated from matter, yet because they are not from themselves and independent, they cannot create. You will press: a material agent can produce something from nothing — namely, form — as (*Philop.*) and (*Ferch. Vestig. Peripat.*) hold; therefore also an immaterial agent, such as the Angel. The antecedent is denied. For form is drawn out from the potency of matter; but the drawing out of form from a subject is not creation but production from something, which differs from creation, as is plain from what was said above.

Objection III: whoever can annihilate can also create, since both are held by all scholastics to be of equal power; but a creature can annihilate something. For man through sin committed by him loses grace, which is the terminus of creation and annihilation; therefore, etc. The major is conceded; I distinguish the minor: effectively, I deny it; demeritoriamente, I concede it, with (*Scot. 3. d. 23. q. un. §. Ad 1. principale L.*). What this means is that man through sin deserves that God no longer conserve grace in him; but not to conserve grace is the same as to annihilate it. You will press: when bread is transubstantiated into the body of Christ, such bread is annihilated; therefore if a creature can annihilate something, it can also create something. I deny the antecedent, since there is a great difference between annihilation and transubstantiation, as (*Alphon. l. 6. adversus haereses, her. 5*) indicates. You will urge: if the consecrated host putrefies and a worm is generated, new matter comes to be, which from what has been said is created; therefore it involves no contradiction for a creature to create something. I say that, given the hypothesis, God creates new matter, on the authority of (*Scot. 4. d. 12. q. 6. D.*), who is followed by (*Ockham cit.*) and very many others.

Article VI: Whether a Creature Can Be an Instrumental Cause for Creating Something

The prior opinion is that of (*Gabriel. Magistri 4. d. bifare §. Hic quaeritur*), (*Suarez disp. 20. Met. sect. 3. l. 7*), (*Hurt. disp. 12. Phys. sect. 7. §. 118*), and certain others, who hold that a creature can be elevated by God as an instrument for creating something. The posterior is that of (*Scot. in utroque 4. d. 1. q. 1*), (*Aur. ibid. q. proaemiali. a. 3*), (*Th. 1. p. q. 45. a. 5*), (*Mol. ibid.*), and others, who deny that any creature can be an instrument of any creation.

Note first and recall from what was said in (*1. 4. q. 5. a. unic.*) what an instrument is — twofold — and add from (*Scot. cit. §. Ad q. ergo EE.*) that if it is repugnant to some nature to be the active principle of certain actions, it cannot by any power

— even divine absolute power — be the principle of those same actions. For although God can absolutely create cold, he still cannot produce cold through heat so that heat would be the per se efficient cause of cold. And (*D. Damasc. 2. fidei, cap. 7*) intimates this, saying that although God can produce something outside the order of created things, he nevertheless cannot bring it about that man be formally a donkey. The reason is that the nature and essence of man is repugnant to the nature and essence of a donkey, since they are constituted by opposed differences — man through rationality and the donkey through irrationality. And not only do the natures of the one conflict with the natures of the other, but also their properties; therefore it is contradictory for a man to beget a donkey, or for one to participate the principles and properties of the other. Therefore, if it is conceded that an instrument properly acts toward producing an effect, it must have in itself an active form in a state of rest, before the motion, just as a secondary cause does — or at least receive in the actual motion an active virtue, by which in its own order of acting it acts toward producing the principal terminus, or toward some prior disposition. So, as a true and universal proposition, it must be established that every instrument that is truly and properly active either acts toward some prior disposition of the principal terminus, or through some form intrinsic to itself attains the principal terminus — though in the power of the principal agent, whether such active principle precedes the motion or is only present to it while it is actually being moved. But if it has neither in a state of rest nor in actual motion an active form, it plainly follows that it cannot act at all; and if it has only of its own nature a passive principle, it cannot have an active principle — otherwise, as repugnant, it would destroy its essence. It is certain and undoubted, however, that God can supply the action of a created agent and not concur with its effect — as in fact he did in the Babylonian furnace, in which the burning fire neither heated nor burned the three Hebrew youths; but it cannot happen that heat should chill, because it is a property of cold repugnant to heat; and conversely, to heat is a property of heat repugnant to cold. The cause of this can be adduced: these properties flow naturally from the essences of their things; and just as the essences are formally repugnant to one another, so likewise their properties and passions — as is evident from man, from whose essence risibility emanates, which is opposed to neighing, which is the property proceeding from the essence of the donkey.

Note second from (*Scot. 3. distinctione prima, quaestione prima. §. Non asserendo. sub F.*) and (*quaestione secunda. Ad argumenta principalia, infra C.*) that human nature — and the same must be asserted of every other nature — is in perfect obedience toward depending upon whatever supposit, through the action of a supernatural agent to whom all things are subject and who do his word, and nothing can resist his will, since he has full dominion and power over all things. Hence, just as God can do many things by absolute power that he cannot do by ordained power — that is, according to the law established and decreed by him — so too

he can accomplish many things in a creature through its obediential power that he cannot accomplish in it by letting the creature itself follow the order prescribed to it. Nevertheless, it must not be thought that through this obediential power a creature can be assumed by God to produce effects that are repugnant to it and impossible — since for the impossible no power exists, whether created or uncreated. Therefore (*Scot. in memorato loco, q. 2*) denies that one singular created nature can be assumed to a hypostatic union conjointly by three divine Persons, because this involves repugnance; it can be assumed by them severally, however, because this involves no repugnance. Although God alone and immediately can produce cold and other absolute accidents, he still cannot bring it about that heat actively concur toward producing cold, because this is repugnant to it, since heat is of such a nature that it possesses not the principle and power of chilling but only the power of heating. God can indeed establish this pact — that when heat is applied, cold is produced, not by heat effectively but by God himself — just as we say regarding the causality of the sacraments, which physically do not attain grace but only morally; that is, because God established with the Church that through such sacraments grace is produced in the one who receives them and places no obstacle — not physically by the sacraments but by God himself.

Assertion: no creature can be assumed by God as an active instrument for creating anything. So (*Scot. 4. d. 1. quaest. 1. §. Ideo dici potest LL.*). It is proved first: what has no form or active principle in a state of rest before any motion of the agent, or in becoming — while it is actually being moved — can in no way act; but a creature participates no active principle toward creating anything — neither in a state of rest, because it cannot be the principal cause of creation, as I showed in the preceding article; nor in becoming, because either it would dispose toward creation, and this is impossible, since in creation there is no subject to be disposed, as it is production from nothing, from no pre-existing subject; or it would attain the terminus of creation, and this too is impossible, since it possesses no creative power in itself. You will say: this is effected not by the creature's own power but by the power of God. Against this: an instrument, before being assumed by God for creating, from the opinion of all, has no power of creating; therefore if it is elevated by God and concurs toward creating, it must newly receive the power of creating — since the same thing remaining the same, without any change in itself, cannot at one time not be active and at another time be active. But a creature assumed by God as an instrument does not receive in itself the power of creating, of which it is incapable, since that is an active power independent of a subject — whereas every creature acts dependently upon a subject. And an instrument when it acts receives the influx from the one whose instrument it is — namely, actual motion, through which it acts in its own order; but that motion proceeds not from the instrument but from the power of the principal mover; therefore a creature cannot be elevated as an instrument of creation. Second: to whom

repugnance toward the first act belongs, to the same repugnance toward the second act belongs too, since the latter proceeds from the former, and when the principle is removed the thing based on the principle is also removed; but to the creature as instrumental cause the first act — namely, the power of creating — involves repugnance, since this is from itself and independent, belonging to God alone; therefore a creature cannot be assumed by God as an instrument of creation.

You will say: the argument concludes concerning a principal cause, not an instrumental one. Against this: an instrument properly is not active, as I proved in the preceding in the first note; and if it operates in any way, it only disposes the subject beforehand — but in creation there is no subject presupposed to be disposed, since it is production from nothing. I add: the obediential power that exists in a creature is not active but passive; therefore a creature as an instrument cannot attain the terminus of creation. Third: two causes properly influencing an effect — however this may occur, whether principally or instrumentally — each put forth its own proper action; and just as there are two causes, so also there are two actions by which the common effect is produced, as (*Doct.*) teaches at the end of the question cited; therefore if a creature is placed as the instrumental cause of creation, in its own manner and order it must put forth its own action and actively concur toward the terminus of creation; but it cannot do this, because it acts dependently upon a subject; therefore it cannot be elevated as an instrument of creation.

Objection I: no less power is required to effect the hypostatic union of the divine Word with humanity than to create something, since both are supernatural works; but a creature can be an instrument of the aforesaid union; therefore also of creation. The minor is proved: the Blessed Virgin was the instrument of the mystery of the Incarnation, for she cooperated toward it, since she was the true mother of God and man. Hence the Church sings: "Holy Mother of God." The major is conceded; the minor is denied. In response to its proof, I say that the Blessed Virgin indeed cooperated toward the humanity of Christ, but the entire most holy union of the Word with that humanity was accomplished by the power of the Holy Spirit, as the Angel had foretold (*Luc. 1*): "The Holy Spirit will come upon you, and the power of the Most High will overshadow you." The Blessed Virgin is called the Mother of God because she bore Christ, who is God and man — though she did not attain the aforesaid union. This can be explained by the analogy of a man generating a man, though he does not produce the rational soul. You will press: a priest is the efficient cause of the transubstantiation of the body of Christ, for which a supernatural power is required, just as for creation. I say he is a moral instrument, not a physical one — as was said of the sacraments that cause grace, and of the humanity of Christ performing miracles, as is written in (*Luc. 5*): "power went out from him, and he healed all."

Objection II: it is equally difficult and arduous for a body to act upon a spirit and for a creature to be elevated as an instrument of creation, since it is a well-known saying that "a body does not act upon a spirit." But the first is possible, as is evident from the fire of hell burning the souls of the damned: (*Luc. 16*): "I am tormented in this flame." Therefore also the second. The major is conceded. To the minor I say that fire acts there only objectively — that is, as an object that is not willed by the damned; and this is an intentional action, not a real physical one. Or say that the damned are tormented in hell as in a most gloomy dungeon and prison in which they are held, on the authority of (*Scot. 4. d. 44. q. 1.*). You will press: in (*4. Reg. 20*) it is narrated that the illness of King Hezekiah was cured by Isaiah through figs — which rather aggravate than heal infirmity, as (*Lyrar. eo in loco*) notes. And in (*Ioan. 9*), the man born blind received sight through clay, which harms vision. Therefore if God can do this, he can do that also. I say these did not concur to the said effects physically but morally — just as if God were to create an Angel at the prayer of St. Francis, that prayer would be not a physical but a moral cause. (*Aur. cit.*) explains this with the example of one who applies tinder to fire, and of the arsonist, who is said to be the burning cause of the house into which he threw fire — when the fire itself truly and physically burns it, not the arsonist.

Objection III: (*Aug. serm. 24. de verbis Apoft.*) writes of that passage (*Matt. 11*): "Learn of me" — says (*Doct.*): "Learn of me not to fabricate the world and create natures, nor even those other things which this hidden God, made manifest as man, accomplished"; therefore Augustine does not consider it unfitting and impossible for a creature to create something — especially if it were elevated by divine power as an instrument of creation. The answer is that Augustine is to be interpreted morally, not physically, as was said in the response to the first objection of the preceding article; or satisfaction will be given if it is said that Christ the Lord there teaches us humility, which is the foundation of the other virtues, and which — united with charity — leads us to happiness and to eternal rest for our souls. Hence the Savior himself adds: "and you will find rest for your souls." And if we knew how the world is to be created, and possessed the knowledge of all things that are in it — without humility and charity — we would be unable to attain that glory and rest. Or the same saint intimates to us that just as it is impossible for a creature to found the World, so it is equally impossible to acquire heavenly beatitude for oneself without humility.

Book II

On the Heaven

Treating of the nature of heaven, its motion, and its influence, we leave the rest for astronomers to consider and observe. Three principal questions are resolved in this book: the first concerning the nature of heaven, the second concerning its motion, and the third concerning its influence. But before taking up these

difficulties, it is our intention to explain the name of heaven. Some hold that "heaven" (*caelum*) is derived from "hiding" (*celando*), because it seems to hide from us what is effected within and above it; others — notably (*Vorrilong* 2. d. 16. art. 1) — derive its meaning from the verb *caelo*, which means the same as "to sculpt"; and certainly in it the stars are marvelously seen as if sculptured, shining and sparkling in a most beautiful field. Its condition is firm, its order certain, and its ornament perfect — so that the royal psalmist not unfittingly sings in (*Psal.* 18): "The heavens declare the glory of God, and the firmament announces the works of his hands."

Question I

On the Nature of Heaven

Article I: Whether Heaven Is Composed of Matter and Form

(*Aver.* 1. *de substantia orbis* cap. 2) and (1. *Cali*, ad tex. 7 and 10), drawing on Aristotle in the places cited below, holds that heaven is a simple body devoid of matter and form. The same view is held by (*Gabriel* 2. d. 12. q. 2), (*Aur.* *ibid.* d. 14. art. 2), (*Dur.*), (*Mayr.*), and (*Arr. disp.* vn. *caeles.* sect. 1), from whom (*Poncius disp.* 51. q. 1) does not depart in fine. The opposite — namely that heaven consists of matter and form — is taught by the rest: (*Alens.* 2. parte, q. 44. m. 3), (*S. Bon.* 2. d. 12. quaest. 1. art. 2), (*Ockham quaest.* 22), (*Th.* 1. p. quest. 66. art. 2), (*Suarez disp.* 13. Mes.), (*Conimb.* 1. *Cali* c. 2. quest. 4. art. 2), and (*Hurt. disp.* 1. sect. 1. §. 7). (*Scot.*, however, in *utroque opere* 2. d. 14. quaest. 1), resolves this controversy with a single distinction, saying that according to the philosophers heaven is a simple body, but according to the theologians it is composite.

Note first from (*Scot. in Rep. cit.* §. *circa istam quaest.*) that it is taken as certain that heaven is not an incorporeal substance, since it is perceived by us as quantified and sensible; but quantity is located only in a material and corporeal substance. The question, however, is whether it is a simple substance or one composed of matter and form. Furthermore, observe that heaven is sometimes taken for air — as in (*Psal.* 8): "the birds of the heaven" — that is, of the air — as (*Aug.* 12. *Conf.* 32) interprets; and (*Psal.* 146): "who covers the heaven with clouds for the rain of the earth." Hence (*Aug.* l. *de natura boni contra Manich.* c. 33) adds: "sometimes the air is called heaven, not that heaven in which the stars are, but this lower one in which the clouds are gathered in darkness and the birds fly; for cloudy sky and the fowls of the air are both so called." This is perhaps what (*Paul.* *Eph.* 6) had in view when he named "spiritual wickedness in the heavenly places." (*Damasc.* 2. *fidei*, c. 6) adds: "the custom of divine Scripture is to call the air heaven." Heaven properly, however, is the container of all visible and invisible things — on the authority of (*Scot.* 2. d. 2. q. 6. paulo ante B.) after (*Damasc.* *mox alleg.*), of which (*Virg.*) sings: "the heavens, the earth, and the deep sea"; and (*Lucan.*): "Olympus exceeds the clouds." And it is this heaven, shown to Abraham in (*Gen.* 15): "Look

up to heaven, and number the stars if you can," of which our present discussion treats.

Note second that form and matter are each used in two ways. Form is taken for the part of a physical composite which, together with matter, causes the composite; and also for the entire nature and essence of any thing — in this sense humanity is called the form of man (*Philip. 2*): "taking the form of a servant" — that is, humanity or human nature, as (*Lyr.*) interprets — and it is called the form of the whole. In this sense too, Angels are said to be simple forms — that is, devoid of physical composition. Matter likewise is taken for the matter of the part, which together with form constitutes the composite; and for the matter of the whole, or individual difference, which is called matter because it is susceptible and subject — just as matter is subject to all forms — as (*Scot. in exp. 1. Met. cap. 4*) observes. Hence (*Arist. 1. cali T. 92*) prefaced: "when I say heaven, I say form; when I say this heaven, I say matter."

First assertion: according to Aristotle and his followers, heaven is separated from matter and is a simple body, which is called the fifth essence of the Peripatetics. So holds (*Doct. in locis memoratis*). It is proved first by strong and efficacious authorities and testimonies of the philosopher (*9. Met. 17*): "heaven is eternal and is not in the potency of contradiction toward being or not being"; but what is composed of matter and form can be or not be (*1. Phys. 12*). The reason is that matter, actualized and informed by one form, inclines and tends toward another form; therefore, because of the privation annexed to it, it contrives harm — that is, the corruption of the composite in which it exists (*1. Phys. 81*). Therefore, in the Peripatetic school, heaven does not consist of matter and form. (*Ruv. in com. 1. de calo, c. 2. q. 5*), (*Conimb.*), and others cited above respond that Aristotle removes from heaven the potency separated from act — or form by which it is actualized and informed — but not the potency conjoined always with act and form by which it is actualized and informed; for this latter can coexist with what is eternal and perpetual, such as heaven. Against this: the same Aristotle there admits only the potency in heaven for accidental form — such as quality and place; but if there were matter there, it would also be indifferent and in potency toward another substantial form, toward which it inclines and tends, if not proximately, at least remotely — since no form, however perfect, can satisfy and fill the appetite of all other forms. Furthermore, if according to Aristotle heaven is a simple body, it plainly follows that it lacks matter, since the simple is opposed to the composite of matter. The same (*the Philosopher 8. Met. T. 4*), (*14*), (*12 of the same work, T. 10*), and (*ibid. T. 30*) proves that intelligences lack matter because they are sempiternal; but heaven is eternal, as is clear from (*1. Cali T. 38 and 39*); therefore it does not possess matter. Second, from (*l. de longitudine, brevitae vitae, cap. 2*): what is assembled from matter is not free from contraries; but the celestial body lacks contraries, as is clear from (*1. cali, c. 3 and 4*); therefore it is devoid of matter. You will say with (*Ruv. cit.*) that heaven has some contrariety — for in one part it is rare, in another dense, and

its motion is fast or slow. Against this: Aristotle there speaks of contraries in the proper sense, which are the primary qualities that are adverse to the life of animate beings, of whose short and long life he was treating; and it is plain that heaven lacks such contraries; therefore the aforesaid response is inapt to the text of Aristotle. Third, from (2. *de gener. c. 1*) and (8. *Met. 14*): what is composed of matter and form is transmutable into each other, as is clear in the elements, one of which is transmuted into another; but heaven is intransmutable and incorruptible (1. *cali, 81*); therefore it is exempted from physical composition. Nor does it avail to say with (*Ruv.*) that heaven is transmuted not simply but in a qualified sense — that is, from one accidental form to another, or to its privation, as from light to darkness, as is evident in night and the eclipse of the sun and moon. For Aristotle in that place speaks of substantial transmutation, through which the philosophers came principally to the knowledge of matter. For if a simple body were given, accidental transmutation could occur in it while it yet lacked matter; therefore the philosopher is to be interpreted of substantial transmutation; and consequently, in his opinion, heaven lacks matter.

Second assertion: according to the theologians and the truth, heaven is composed of matter and form. This is defended by (*Doct. in locis praememoratis*) and is proved first from Sacred Scripture (*Sap. 11*): "he who created the world made it from formless matter" — that is, as (*Lyra*) expounds, from prime matter, which is called invisible because it is not knowable by us except by analogy with form, though in itself it is knowable, as was asserted in (*Phys. 1. 2. q. 1. art. 14*). Or, as (*Aug. 2. de gen. ad lit. 11*) interprets: "he made the World from formless matter," which is called chaos extending from the earth to the empyrean heaven — as (*Scot. ubi supra*) expresses, following (*Alensen. praecit.*) — from which heaven and the other bodies were compacted. Second, from the holy Fathers cited by (*Aur. art. 2*), (*Suarez*), and (*Conimbr. praecensitis*) — it suffices to name and cite one: (*Aug. in the passage just adduced*) and also (2. *de gen. contra Manich. 7*) and (l. 2. *contra Adversarium legis et prophetarum cap. 8*), fortifying our conclusion with the authority already cited by us from (*Sap. 11*). These were preceded by Plato, Democritus, Empedocles, and other earlier philosophers who embraced and confirmed this truth, as (*D. Th. 1. p. q. 66. art. 1*) attests. Third: heaven has being in act, since it is truly seen to exist in the nature of things. Therefore either it is act, or it has act; but it is not act — whether perfect, for then it would be an intellectual nature, or imperfect, for then it would be form, which cannot be the rational soul or any of those belonging to the sublunar realm, as is plain in itself — it remains, therefore, that it is something having act. But what has act certainly possesses a potency for receiving it; and such a potency that is receptive of act is matter; therefore heaven is assembled from matter and form. Fourth: heaven is sensible and material, receiving in itself the accidents appropriate to the composite — such as magnitude, rarity, density, transparency, figure, color, and the like; therefore heaven is endowed with composition.

Objection I against the first assertion: (*Arist. 1. cali, c. 2. T. 5*) proves that celestial spheres are moved circularly because they consist of natures; but natures are matter and form, and the composite is what has a nature; therefore celestial bodies are composed of matter and form. Consequence: the same author (*ibid. T. 92*) writes in explicit words that heaven consists of matter. And (*ibid. T. 94 and 95*) he adduces the reason why another heaven cannot be made — because it is assembled from all matter, so that in its production all matter was exhausted. Furthermore (*2. de generatione c. 9. and 7. 51*) and (*12. Met. T. 22*) he affirms that the principles of sublunar and celestial, temporal and eternal, corruptible and incorruptible things are the same; therefore matter is not to be banished from heaven. The answer is that the philosopher in that text asserts that natural bodies are moveable and that celestial ones are moved with circular motion; but he makes no mention of matter there, whatever (*Conimb. in eius expositione*) may say. Or, given the hypothesis that he asserted this, he is to be interpreted not of the matter of the part but of the matter of the whole, taken for the individual difference, as I observed at the end of the second note; or of the matter with respect to place (*ad vbi and circa quam*), not of the matter from which (*ex qua*). To the consequence, I say that Aristotle there speaks of the world, which according to him is necessarily produced by God, so that another cannot be made; and even if he subsequently asserts the same of heaven, he is still not to be interpreted of the matter of the part but of the matter of the whole — for which reason he prefaced in (*T. 92*) that heaven is among those things that are singular. And then: "when I say this heaven, which is singular, I say matter." Through this distinction satisfaction is also given to the other places cited. And it can be added that Aristotle speaks of metaphysical principles, which are genus and differentia, and which are said to be in some sense matter and form — which (*8. Met. 14*) plainly observes and explicitly writes: "Not every matter is that of whose generation and mutual transmutation there is something; but of those that exist without transmutation, there is no matter of these."

Objection II: the same Stagirite (*2. animae, c. 1. T. 2*) divides substance into matter, form, and composite, and says that a natural body consists of matter and form; but heaven is a natural body; therefore it consists of matter and form. The answer is that this is to be interpreted of a sublunar body that is generable and corruptible, not of a celestial one that is ingenerable and incorruptible, and of a natural simple body such as heaven is in his opinion.

Objection III: what receives the same accidents as a generable and corruptible body participates the same matter; but heaven shares the same accidents by which a sublunar body is informed — for it is quantified, figured, colored, and subject to the senses, even according to (*Arist. 1. cali 22*); therefore it is also composed of matter and form. The answer is that this is indeed a probable argument, but is not demonstrative; for since the said accidents are common, they do not lead us to proper and evident knowledge of the nature of the celestial body. For Aristotle would say that a simple body has and participates

those same accidents as a composite body, and would therefore deny the major. Especially because their proximate and immediate subject is not matter but body — whether simple or composite — as was decided in (*Phys. 1. 5. q. 1. art. 4*).

Article II: Whether Heaven Is Distinct from the Elements

There existed an opinion of the ancient philosophers before Aristotle, who held that heaven was a body assembled from elements — though they disagree among themselves. For some — as may be seen in (*Conimb. 1. Cali, c. 2. q. 5. a. 1*) and (*Ruv. ibid. q. 4*) — hold it to be fiery; some aerial, others aqueous, and yet others earthy, or something not very different from sublunar things. The common opinion, however, is that of (*Arist. 1. Cali, c. 2 and 3*) and of later philosophers and theologians at (*2. d. 14*), who teach that heaven is a body distinct from the elements and from all sublunar things.

Note from (*S. Bon. 2. d. 14. q. 1. q. 2*) that the dispute between the Peripatetics and the holy Fathers — who agree with the ancient philosophers and hold that heaven is made of the elements or of some element — is more about words than about the matter itself. For although (*D. Aug. 2. de gen. ad lit. c. 3*), (*Ambr. 2. Exam. c. 3*), and others not few in number say that heaven is fiery, they do not appear to hold that it is truly of a fiery nature, but as regards likeness — that is, because it is luminous, like fire. Similarly heaven is called aqueous — as the same holy Doctor observes (*ubi supra, q. 1*) — because it has a certain likeness to water, namely because it is transparent like water, and also because it retains light as water does. But if this does not satisfy you, take that saying of (*D. Aug. 19. Civit. c. 3*) at the end: "We ought rather to judge of things themselves than of what each person has thought." For very many of the holy Fathers followed Plato, who held that heaven participates a fiery nature. Thus the philosophers maintained this doctrine, whose opposite Aristotle first introduced into the schools, and which the generality of scholastics subsequently embraced. And if both sides seem uncertain to you, take that saying of the Seraphic Doctor cited above: "In doubtful matters it is better to doubt piously than to define anything rashly."

Assertion: heaven is a body distinct from the four elements and from all sublunar things. So holds (*Doct. in utroque opere 2. d. 14. q. 1*), not far from the beginning; (*Gabriel ibid.*), (*Lyran. in expos. Gen. 1*), and younger sacred interpreters. It is proved first: the corruptible and the incorruptible differ by more than a genus (*10. Met. 26*); but heaven is incorruptible, while the elements are corruptible — at least with respect to their parts — and the other sublunar things are in their entirety subject to birth and death; therefore heaven differs from all of these. You will say: both the sublunar and inferior things, and the celestial and higher things, are corruptible, as is clear from (*2. Petri 3*): "the burning heavens shall be dissolved, and the elements shall melt with fervent fire." The objection is to be met with (*Lyr.*), who says that text is to be interpreted not according to substance but according to accidents. Hence the sacred text adds: "We look for new heavens and a new earth and his promises." For after the

day of judgment all things are to be changed, renewed, and purged by fire, as the aforesaid Postillator there observes. Second: what is moved by a proper and peculiar motion distinct from the motions of others is a body distinct from and diverse from them — as (*Arist. 1. cali cit.*) argues; but heaven is moved by its proper motion — namely, circular — while the elements and other bodies are moved by straight motion, upward or downward, as experience shows in fire which is borne upward and in earth which falls downward; therefore heaven differs from these. You will say: fire also moves circularly, as is seen in ignited comets which are seen by us to revolve, therefore circular motion is not proper to heaven, by which we may know its distinction from fire and the other sublunar things. I say that fire indeed moves circularly in its own sphere, yet that motion is not from an intrinsic principle — as heaven moves — but from an extrinsic one — that is, from heaven, by whose motion fire itself is drawn, just as a rope attached to a wheel revolves with it. Third: the place, position, and influence of heaven plainly demonstrate that it differs from the other things mentioned. For its place is the highest, containing and revolving all sublunar things, reconciling contraries to harmony — for it is the universal cause of mixtures, both living and non-living — separated from all contrariety. Furthermore, it pertains to the ornament and complement of the universe, that just as there are elements that contend and mixtures resulting from their strife, so there should exist a body containing them all, superior, greater, and more sublime, brightened with luminaries, endowed with fixed and wandering stars, and separated from all the dross and disturbance of sublunar things — such as heaven is. All the more so since it is the dwelling-place of the Angels and of all the Blessed, in whom God is seen and possessed. The reason of (*Arist. 1. Meteor. 3*) is also relevant: if heaven were fiery, since it is much greater and more powerful than the rest, it would by now have burned and reduced everything to ashes — and this reason, though peculiar to fire, can nonetheless be applied to the other elements. For if heaven were aqueous, it would by now have flooded and devastated everything; and the same would be asserted of air and earth, since it is of immense magnitude and power. The opinion of Aristotle must therefore be held, teaching that heaven is of a different nature from the elements and from all sublunar things.

Objection I: the same accidents argue the same subject and the same substance, according to (*1. de anima, T. 11*): "Accidents contribute much to the knowledge of substance"; but the same accidents are located in heaven and in sublunar things — namely, quantity, density, rarity, and the like; therefore heaven and the sublunar things do not differ from one another. I distinguish the major: the same accidents argue the same essence and nature from which they flow — proper ones, I concede; common ones, I deny — as is clear from sugar, the swan, and other things in which the same whiteness and other accidents are located, though they participate a distinct nature and essence.

Objection II: in (*Gen. 1*) it is read that God divided the waters that were under the firmament from the waters that were above the firmament; therefore in heaven there are waters, as (*David, Psal. 118*) clearly sings: "Waters that are above the heavens, praise the name of the Lord." And consequently heaven is assembled from the element of water. (*Seraph. nuper alleg. q. 1*) responds, and after him (*Scot. 2. Rep. d. 12. ad finem q. 1*), that by the waters that are above the heavens is meant the crystalline heaven, which on account of its transparency and diaphanousness appears to be aqueous, though in truth it is not aqueous but only similar to water by way of likeness.

Objection III: heaven is called ethereal and empyrean, and this latter is named from fire. And where Moses writes: "In the beginning God created heaven and earth," Plato writes that God first made fire and earth, meaning heaven by fire. Moreover, the entire mass of heaven is called fiery and warm; therefore heaven is assembled from fire. The Seraphic Doctor responds that heaven is called fiery by likeness, because it participates light that shines and gleams like fire. And the empyrean is called fiery not from elemental fire but from the fire of love with which the Blessed burn. Hence the first order of Angels is called Seraphim from the ardor of love and charity — just as Cherubim are named from knowledge — as (*Scot. 4. d. 49. q. 4. §. Iuxta. K.*) notes. And it is signified in (*Cant. 5*): "many waters could not extinguish his charity."

Objection IV: what is capable of contrary qualities is an element or a compound — as is acknowledged by all; but heaven is capable of contrary qualities: for Saturn is cold, the Sun hot, Mars dry, and the Moon humid; therefore heaven does not differ from sublunar things. The major is conceded; I distinguish the minor with (*Scot. q. 4. prol. GG.*) and (*1. d. 3. q. 7. Sub R.*) and (*Quol. 15. §. Ad 1. principale ante BB.*) and (*2. d. 25. q. un. sub G.*): formally, I deny; virtually, I concede.

Article III: Whether the Matter of Heaven Is of the Same Species as the Matter of Sublunar Things

Those who — with (*Dur. 2. d. 12. q. 1*) — hold that heaven is simple and devoid of physical composition are free from this difficulty. Those who, however, hold that heaven is composed of elements or of other things rightly investigate whether its matter is of the same or different species from the elements and the other sublunar things. On this matter there are two opinions: one is that of (*Alens. 2. p. q. 44 in 2*), (*Ric. 2. d. 12. q. 8*), (*Th. 1. p. q. 66. art. 2*), (*Caiet. ibid.*), and others, who hold that the matter of celestial things differs in species from the matter of terrestrial things. The other is that of (*Scot. 2. d. 14. q. 1*), (*S. Bon. d. 12. q. 1*), (*Ockham q. 22*), (*Aur. d. 14. q. 1. art. 2*), (*Racon. tract. de principiis sect. 1. art. 4*), (*Mol. tract. de opere sexdierum, disp. 5*), and (*Arriag. disp. 2. Phys. sect. 11. subsect. 2*), who teach that incorruptible and corruptible, superior and inferior bodies participate the same matter in species. These were preceded by Trismegistus,

Empedocles, Heraclitus, and others cited by (*Ruv. 1. Cali cap. 2. q. 6*) and by (*Conimbr. ibid. q. 5. art. 1*).

Note that although matter is in itself indifferent to receiving any form whatsoever, nonetheless certain forms can be separated from it by a created agent and in fact are separated — as is clear in the perpetual origin and death of sublunar things; but certain others are inseparable by the same agent, since it cannot introduce the prior contrary dispositions that would inform that matter with the said forms — as appears in some way in the diamond and others in which the bond between form and matter is necessary and almost indissoluble, such as the form of heaven; yet absolutely, one can be separated from the other if an agent were given that could overcome its power and introduce opposing and conflicting preparations and dispositions through which the matter could be prepared to receive a form different from the one it has.

Assertion: the matter of the celestial and the terrestrial is of the same nature and species. So holds (*Doct. cit. in utroque opere*). It is proved first: what participates the same definition is of the same nature and species, because the definition signified by the name designates and explains the nature (*4. Met. 28*); but the matter of terrestrial and celestial things — of corruptible and incorruptible — has one and the same definition (*1. Phys. 82*). For both are the subject of forms, whether corruptible or incorruptible; nor is any other definition of matter found in the writings of the philosopher. Again: in the foundation of nature, such as matter, there is nothing distinct — as (*Dur. nuper alleg.*) reports from Averroes, after (*Scot. q. 15. de anima, §. Ad q.*); but there would be something distinct if sublunar matter were specifically different from celestial matter — for between the two there would be a specific distinction that would destroy the aforesaid saying celebrated by all. Second: such a specific difference between this and that matter is established either on account of the nobility or on account of the incorruptibility of the form; but neither can introduce such a specific distinction of matter into sublunar and celestial things. And indeed not the nobility and excellence of form — for the rational soul surpasses and excels all other forms of these inferiors, yet the matters of this and of those do not specifically differ from one another; nor the incorruptibility of form — for one star possesses an incorruptible form distinct from the form of another star, and yet no one asserts that the matter of one specifically differs from the matter of the other. Third: common and identical accidents argue the same subject and common matter, as (*Arist. 1. anima 11*) signifies; but superior and inferior bodies share the same accidents — namely quantity, transparency, density, rarity, light, and the like; therefore also the same subject and the same matter. Fourth: there are not two first efficient causes and two ultimate ends, as (*Scot. 1. d. 2. q. 2*) demonstrates; therefore neither are there two prime matters, since the reasoning is equal in both cases. This doctrine is corroborated from Sacred Scripture. For in (*Gen. 1*) prime matter is signified by earth, as (*S. Bon. I. praecit.*) notes; or by water, as other doctors observe. It is therefore certain among all

sacred interpreters that God created only one matter, from which all things consist, as is expressed in (*Sap. 11*): "he who created the world made it from invisible matter." Pressed and convinced by this argument, (*Mol. pallu memorato*) embraces our opinion, though he honestly confesses that he held the contrary elsewhere. (*Aug. 2. de gen. ad cit. cap. 21*) adds: "from this same corporeal matter, heaven is narrated as already made." The same holy Doctor indicates this in (*2. de gen. contra Manich. cap. 7*) and (*12. Conf. cap. 7 and 8*). All the Fathers cited in the preceding article subscribe to this, who hold that heaven is assembled from the elements or from some of them; for if heaven participates the matter of the elements, and consequently of inferior things, the matter of inferior and superior bodies is of the same nature and species.

Objection I: (*Arist. 1. de gener. cap. 10. T. 54 and elsewhere*) plainly expounds that what participates the same matter in species is mutually transmutable; but heaven is intransmutable, and all sublunar things are transmutable; therefore its matter is specifically distinguished from the matter of these. The same is indicated in (*8. Met. c. 4. T. 12*): "In everlasting things, such as the heavens, the matter is not the same as in perishable things." And in (*12 of the same work, cap. 2. T. 10*): "In sempiternal things, such as celestial bodies, the matter is plainly diverse from temporal and corruptible things." The same (*S. Dionysius 4. de divinis nominibus*) signifies. The answer is that Aristotle is to be interpreted of accidental, not essential distinction. For in the matter of heaven there are not, nor can there be by natural powers, proximate dispositions and suitable preparations for another form — as there are in these inferiors — and therefore these are mutually transmutable but that is not. Or it can be interpreted of the matter *in qua*, not the matter *ex qua*. And this is explicitly intimated in the last cited passage, where he says that the everlasting undergoes change of place and motion. Or say that he speaks of matter not of the part but of the whole, taken for the haecceity or individual difference, as I observed above. Dionysius in the place cited is also to be interpreted in this way. All the more so since Aristotle posits heaven as the fifth simple body, separated from all matter, as is clear from what was proved in (*art. 1 of this q. aff. 1*).

Objection II: the matter of heaven is bound with an indissoluble connection to its form, since it is necessary and perpetual; but the matter of sublunar things is bound to form by a dissoluble and contingent bond, as the continuous and perpetual birth and death of things makes plain; therefore the one specifically differs from the other. The answer is that this is true proximately and in a qualified sense, but not remotely and absolutely. For in fact heaven is incorruptible because no created agent contrary to it is given that could overcome its power and introduce opposing and conflicting dispositions in it, through which it could be prepared to receive a form other than what it has, as I made clear in the preceding note. And (*Damasc.*) indicates this with these words: "By the will of God, heaven is incorruptible." And (*Ockham nuper alleg.*) pursues this aptly after (*Scot.*). You will press: if the matter of heaven were in passive

potency to receive another form, since active potency corresponds to passive potency, it follows that there exists in the nature of things a created agent that possesses this active power of informing such matter with a form different from the celestial form — and consequently that heaven is in fact corruptible, which is false. The sequence is to be denied; for it suffices that in the entire coordination of beings there be such an agent — such as God — as is evident from the human body duly organized to receive the rational soul, which God alone can create and infuse into it, as (*Scot. q. 1. prol.*) and (*4. d. 43. q. 3. §. Ad arg. principalia*) note.

Objection III: the matter of heaven is receptive of foreign impressions, as the common view of philosophers and astronomers at (*1. Meteor*) asserts; but the matter of the earth is also capable of such accidents; therefore they specifically differ — otherwise both would be endowed with all of them. The answer is that those accidents are common, from which a specific distinction of one from the other cannot be detected — especially since the proximate and immediate subject of accidents is the composite, not matter or form.

Article IV: Whether Heaven Is Animate

The affirmative side is supported by the weight of the authority of almost all the ancient philosophers to such a degree that (*D. Aug.*) appears undecided, as (*Scot. 2. d. 14. q. 1. §. secundum Theologos D.*) and (*Aur. ibid. q. 2. art. 2*) above all note. And it was so prevalent at that time that (*Anaxagoras*), holding that the sun was inanimate, was charged with and condemned for impiety by the Athenians, as (*Laertius in his life*) attests. But the negative side is now the most common, and the opposite is considered erroneous by the (*Seraphic Doct. 2. d. 14. art. 3. q. 2*) and condemned by the University of Paris, as may be seen in (*collect. errorum, cap. 12*) at the end of (*4. Magistri*) and at the beginning of (*1. S. Bon.*); and also by (*D. Hieron. in com. Deut. 32*) and (*Isa. 1. 45*), where it is reckoned among the errors of Origen; indeed, in the Fifth General Council those who maintain the opposite are struck with anathema, as (*Joverius tom. 2. summae Conciliorum*) reports.

Note and recall from what was said in (*2. Phys. q. 4. art. 1*) that form is divided into assisting and informing, as (*Arist. 1. de partib. 1*) indicates. An assisting form is extrinsic to the thing it assists, moves, and fosters — in this sense a sailor is called the assisting form of a ship, and a charioteer of a chariot. But an informing form is intrinsic and essential to the thing — for it together with matter essentially and intrinsically causes and integrates the whole, which is truly actualized by it and animated, if it is living or life-giving.

Assertion: heaven is not properly animate. So (*Scot. cit.*) and (*in Rep. ibid.*) and (*8. Met. in expos. cap. 18*), (*Picol. lib. de calo, cap. 19*), and others cited by recent authors. It is proved first from the holy Fathers: (*Ambr. 2. Hexam. cap. 4*), (*Basil. ibid. homil. 3*), (*Cyril. 2. contra Julian.*), (*Damasc. 2. fidei, 6*), (*Lyran. in cap. 10. Ierem*), and (*Abul. in cap. 23. Exod. q. 47 and elsewhere*), who maintain and profess the

proposed assertion, supported by (*Mayron.*), (*Ockham*), (*Gabriel.*), (*Ric.*), (*Lych.*), (*Pelbar.*), and other professors of scholastic discipline. Second, from (*Arist. 2. animae, cap. 1. T. 37*): "the soul is the first act of an organic body potentially having life"; but heaven is not an organic and heterogeneous body but a similar and homogeneous one of immense magnitude, in which a soul cannot dwell, since it requires determinate organs and members for the performance of vital operations, as was decided in (*lib. 5. Phys. q. 4. art. 1*); therefore the celestial orbs are inanimate. Third: if heaven were animate, it would be animated either by a vegetative, or a sensitive, or an intellective soul; but none of these three animates it; therefore it is inanimate. The major is evident, since only those three genera of souls mentioned are given. The minor is shown: if it were informed by a vegetative soul, it would be nourished, would grow, would generate something like itself, and would be corrupted in some of its parts — since the aforesaid operations cannot be performed without corruption. But if it were endowed with a sensitive soul, it would be sensitive, and would be endowed at least with the sense of touch, would be subject to heat, cold, and other qualities — and thus would be passible, like an animal. But if it had a rational soul, it would be capable of merit, demerit, glory, punishment, eternal salvation and damnation — all of which are most absurd things, as (*Scot. Quol. 9. §. de tertio*) touches upon. Furthermore, it has been established at the Lateran Council, *Firmiter*, that God created only two intellectual creatures — namely, the angelic and the human; but it is evident that neither of these is the celestial mass, from which no vital work is seen to proceed. For local motion absolutely is not a vital action, since it can also be performed by things lacking life and can be performed by an assisting form, as I noted in the preceding note. That our assertion cannot be demonstrated, (*Aur.*) and (*Arr. praecit.*) contend, and (*Scot.*) indicates at the end of the (*q. scripti Oxoniensis alleg.*). And before him (*Aug. 1. Retract. cap. 10*) says: "either this world is such as Plato thought, and as many other philosophers held, and I was not able to discover it by right reason, nor was I able to be persuaded by the authority of the divine Scriptures."

Objection I: (*Isa. 1*): "Hear, O ye heavens, for I speak." But to hear pertains to things animated with a sensitive or intellective soul; therefore the heavens that hear are animated. (*Psal. 135*) adds: "who made the heavens by understanding" — but those that understand, live. Add (*Ecclus. 1*): "The spirit goeth around in a circle" — that is, the sun performs its circles. But the spirit lives; therefore the sun is animated. The answer, following (*Hieron. in expos. eorum locorum*), (*Ric.*), (*Scot.*), and (*Bon. cit.*), is that these testimonies are to be taken metaphorically, as the subsequent words indicate: (*Isa.*): "and let the earth hear with its ears." And (*Deut. 32*): "let the earth hear the words of my mouth." But it is plain that the earth is not properly animate; neither, therefore, are the heavens. This is made clear by (*Daniel 3*), where inanimate things are invited to praise and bless the Lord: "O ye ice and snow, bless the Lord." But such praise and blessing is transferred and metaphorical — and so also is the hearing of the heavens. To the

other text from the Psalter, "who made the heavens by understanding" — that is, in wisdom — as (*Aug.*) interprets; for as it is had in (*Psal. 103*): "You made all things in wisdom." Or say with the same Doctor that by "heavens" are meant the saints, to whom God has given not only hearing but also the understanding of divine gifts. The same (*Damasc. 2. fidei, 6*) teaches, explaining the words of (*Psal. 95*): "let the heavens be glad, and let the earth rejoice" — he calls the Angels who are in heaven and the men who are on earth to rejoicing. To Ecclesiastes I say that its passage is to be interpreted effectively, not formally — for the sun is an equivocal and universal dispositive cause of sublunar living things. Hence (*Arist. 2. Phys. 26*) adds: "the sun and man generate man."

Objection II: (*Arist. 2. Cali T. 13*) expressly says that heaven is animate; and (*ibid. T. 61 and 68 of the same book*) attributes life to heaven; therefore in the Peripatetic school heaven is animate. The answer, following (*Scot. in Rep. cit.*), is that the philosopher attributes a soul to heaven not through information but through assistance. Or that he speaks in the opinion of Plato and the common people, lest perchance, like Anaxagoras, he should be accused and condemned. Or perhaps he holds wrongly on this matter, as on the eternity of the world and certain other things recounted elsewhere.

Objection III: (*S. Aug. lib. de agnitione vera vitae*) writes: "those who say that the heavens are rational, they themselves are rightly irrational"; therefore Augustine does not favor the opposite opinion. The answer, following (*Scot. passu alleg.*), is that the book is not Augustine's — for it does not have the flavor of his style, as is evident to those who read it. You will press: the same saint in (*lib. de duabus animabus*) writes in explicit words: "a fly, because it lives, is nobler than the sun." The same appears to be asserted in (*1. Retract. 5*) and (*2. eiusdem operis, cap. 7*). The answer is that there he speaks not assertively but doubtfully — and sometimes according to the mind of Plato, to whom he is very favorable, as is evident from his opinion about Angels, which he held to be corporeal, like Plato. Therefore he does not appear to adhere firmly to one part, just as in the similar case of (*18. Civit. cap. 11*), where having set forth opinions about the number of persecutions of the Church, he inclines no more to one than to the other. And in the same work he dissents in many things from (*D. Hieronymus*), though the latter was a saint; and in (*lib. 21*) he admits as true certain things narrated by others, while not conceding others but doubting about them, as is evident in (*lib. 22. cap. 13*); and in (*lib. de beata vita*) and elsewhere he honestly admits that he is ignorant of many things. And we can say of him what he himself says of (*S. Cyprian*) against the Donatists: "his authority does not deter me, because his humility delights me."

Objection IV: a soul is defined in (*2. anima T. 13*) as the principle of motion; but heaven is moved, as we experience every day; therefore it is animated by a soul that informs it. The answer is that heaven is not moved by an intrinsic principle

but an extrinsic one that assists it, as I made plain in the preceding note; therefore it is not established as animate.

Article V: Whether Heaven Is Fluid or Solid

Some — among both ancient and modern philosophers — fall into the opinion of asserting that heaven is fluid and penetrable, such that the stars and constellations move in it as birds in the air and fish in the water. Others, while admitting that the firmament or starry heaven is firm and solid like stone or iron, hold that the remaining heavens, in which the planets are situated, are permeable and passable — to which view the Seraphic Doctor (*2. d. 14. art. 1. q. 2*) appears to lend his support. The common opinion of the other philosophers, toward which (*Scot. 2. d. 14. q. 2*) inclines, establishes all the heavens as firm and solid, and (*S. Bonav. ibid. q. 2. a. 2*) indicates the same.

Note that in Sacred Scripture (*Gen. 1*) the firmament is especially named among the celestial orbs — so called from the firmness and solidity with which it is endowed, as (*Lyra in postilla loci mox alleg.*) observes, after (*Aug. 2. de gen. ad lit. cap. 10*) in these words: "it is called firmament not on account of its immobility, but on account of its firmness, or on account of its indivisible separation of the upper and lower waters, it may be understood to be so called." The same (*Calepinus in verbo firmamentum*) notes.

Assertion: heaven is solid — whether it is the firmament or whatever other orb superior or inferior to it. This is intimated by (*Doct. passu memorato*). It is urged first from Sacred Scripture in the place cited and in (*Iob. 37*): "You who with him spread out the sky, solid as a cast mirror." But where the words of Sacred Scripture are explicit, they are not to be twisted to another sense, as some do — saying that the firmness of the heavens does not coincide with solidity. For if the heavens are most solid, as Scripture attests, they certainly have solidity, just as white walls have whiteness in which it inheres; especially since it is added: "solid as cast brass." But it is plain that brass is solid; therefore the heavens are solid, because they are likened to brass itself in solidity. Nor is it valid to say with (*Camerarius*) that this saying was not approved by God but reprehended — for it is not Elihu who uttered that speech, but Job, to whom God was speaking, who is rebuked. Add that the same is received in Sacred Scripture, as (*Psal. 32*): "By the word of the Lord were the heavens made firm." Furthermore (*Isa. 51*) it is foretold that the heavens will melt; therefore now they are not liquid, but solid — otherwise that prophecy would be vain and void. Moreover (*Hebr. 4*): "We have a high priest who has passed through the heavens." But something fluid and liquid is not penetrated, because it yields to a hard and solid body — as is clear from air yielding to a stone thrown into it, and from water yielding to lead falling into it and giving it place. All the more since it is narrated by (*D. Paul*) as a great miracle — as if the heavens were fluid, it would not be a miracle, just as it is not a miracle for fish to pass through the sea or bees to permeate the air. Moreover, it is signified there that two bodies were in the same place

simultaneously — just as when Christ came forth from the womb of the Virgin with the virginal enclosures sealed, and from the tomb with it remaining closed, and when he entered the upper room through closed doors to his disciples. Therefore our opinion is consonant with the principal mysteries of our faith, while the opposite is dissenting from them, and (*Dur.*) — from the sectarians rejected and routed elsewhere — favors it. Second, from the holy Fathers, cited and gathered by (*Tannerus tom. 1. de creatione Mundi, q. 3. dub. 2*) — and (*Lyr.*) agrees with them; and (*Arr. disp. un. Sect. 3. subsect. 4*) subscribes, saying that their testimonies are plainer and clearer than the opposing ones. Third: what is fluid and penetrable is corruptible at least in part, as is clear from air, water, and the like; but heaven is incorruptible, as will be said in the next article; therefore heaven is not fluid and permeable. Fourth: if heaven were fluid, a vacuum would be produced. For if the stars were to move from one place to another, the place abandoned by them would not be filled by another body, as (*Scot. cit. §. Ad videndum. A.*) rightly pursues; therefore naturally a vacuum would be given, which was refuted in the question on the vacuum. Many other things I do not gather, since according to (*Aug. nuper recensito*), where there are open testimonies of Sacred Scripture — and I add, perspicuous authorities of the Fathers — it is superfluous to add further arguments.

Objection I: (*D. Ambr.*), (*Basil.*), and the Nicene Council in the Hexaemeron, and others cited by (*Arr. subsect. 2*), plainly assert that the heavens are fluid and permeable; therefore the contrary opinion contradicts the holy Fathers. The answer is that those Fathers do not speak assertively but doubtfully and dialectically; or if they truly affirm it, they are not to be followed in this — both because there are other Fathers and authors of no lesser name and authority on our side, and because Sacred Scripture and stronger and more efficacious reasons support us.

Objection II: sometimes there have been seen phenomena — such as comets and other meteorological things — above the lunar orb; but these are fluid, as is plain; therefore heaven too is fluid. The antecedent is denied. For as (*Tann. cit.*) rightly says, meteors, even if they sometimes appear to transcend the moon, do not in reality pass beyond it, but are below the moon itself — since they do not ascend except to the uppermost region of the air. Therefore the appearance of those meteors is deceptive, as they also appear to mount up to the stars. Indeed, sometimes clouds appear to exist above the sun, and the sun itself sometimes appears to be triple — the opposite of which is plainly established. Such appearances, therefore, are illusory and empty.

Article VI: Whether the Heaven is Incorruptible

Those who follow Aristotle (*1 Caeli, cap. 3, 7, 20 & 2, eiusdem operis, 1*) hold that the heaven is a fifth simple body distinct from the elements, and they affirm that by its very nature it is incorruptible and everlasting. Those who, together with the early philosophers, hold that the heaven is composed of the elements or of

some one of them, make the heaven corruptible and temporal. Those who maintain that the heaven consists of matter and form — though not of the elemental and sublunary kind — and who acknowledge it to be incorruptible, nonetheless dispute the manner in which it exists as incorruptible. For some, whom Suárez (*disp. 13 Met., sect. 11, 7, 13*), the Coimbrans (*1 Caeli, lib. 3, q. 1, art. 2*), and Ruuius (*ibid., q. 1*) cite and follow, hold that the heaven is intrinsically and by its own proper nature incapable of generation and incorruption. Others, however, such as Scotus (*11 Met., sum. 2, in the exposition of cap. 3; & 2, d. 14, q. 1; & 4, d. 49, q. 6, §. Hic duo, sunt sub B.*), Antonius Andreas (*8 Met., q. 4*), Mauritius (*Theor. 16*), Joannes de Magistris (*1 Caeli, q. 2*), Tartaretus, and the Parisian masters, teach that from its own intrinsic principles the heaven is by nature corruptible, but that extrinsically and in fact it is incorruptible and incapable of generation.

Note that this controversy can be treated in two ways: either concerning what is actually the case, or concerning what is possible — or, as others express it, either proximately or remotely. Likewise it can be treated intrinsically or extrinsically, that is, whether the heaven possesses within itself a principle of corruption, or whether there exists an extrinsic principle — such as some natural agent — that is capable of corrupting it. Whether a supernatural agent could accomplish this falls outside the dispute, since the heaven, like all other created things, subsists by God's will and is governed by his wisdom, and if he were to withdraw his hand from them they would return to nothing.

According to these two distinctions set out above, the entire difficulty is resolved and dissolved by means of the two following assertions.

Assertion I. In fact, the heaven is incorruptible. This is held by the Doctor (*cit. & in Rep. ibid.*) and is intimated by Augustine (*3 de libero arb., cap. 23*). It is proved first from the common judgment of philosophers, astronomers, and theologians alike, to oppose which is rash, in accordance with the admonition of Ecclesiasticus IV: *Ne coneris contra ictum fulminis* — "Do not strive against the stroke of lightning." This is especially so because these grounds are exceedingly solid and firm, as was shown from sacred scripture in the preceding article. Second, it is urged by the experience of so many thousands of years during which the heaven has always endured and been preserved uncorrupted in its entirety and in all its parts; for if it were corruptible, the whole or at least some part of it would already have been corrupted and consumed, the contrary of which is evident to all. Third, there exists in the nature of things no agent capable of overcoming the heaven's power and destroying it, since its power is greater than the power and force of all sublunary things. Therefore, in fact and proximately, the heaven is incorruptible.

Assertion II. In the order of possibility and remotely, the heaven is corruptible. This is defended by the Doctor (*cit., and especially 4, d. 49, q. 6, §. Hic duo cap. in solut. 2*) and may be urged first from sacred scripture. Job XIV: *Homo postquam*

dormierit, non resurget, donec atteratur Caelum — "Man after he has fallen asleep will not rise again until the heaven is worn away." And from other testimonies to be adduced below, in which it is expressly stated that the heaven will be corrupted and will perish. Second, from the Fathers — namely Basil, Ambrose (*1 Hexam., cap. 6*), and Augustine (*26 Civit., cap. 18*) — who affirm that the heaven will at some point be dissolved and destroyed. Plato and other earlier philosophers lend support, holding that the heaven is composed of elements and therefore subject to corruption. Furthermore, what is constituted of matter is subject to corruption, since privation is annexed to matter and works the destruction and corruption of the composite (*1 Phys., T. 81*); but the heaven is composed of matter, and therefore is liable to corruption. More particularly, because the form of the heaven, which informs and actuates its matter, does not contain formally or eminently the remaining forms toward which that matter inclines and tends as toward its own perfection and completion; therefore the heaven is of itself and by its intrinsic principles corruptible, as Scotus (*loco proxime memorato*) excellently pursues.

Objection I against the first assertion. Psalm CI, the royal psalmist speaking of the heavens says: *Ipsi peribunt, tu autem permanes, & omnes sicut vestimentum veterascent* — "They shall perish, but thou dost remain, and all shall grow old like a garment." Matthew XXIV: *Caeli & terra transibunt* — "Heaven and earth will pass away." And 2 Peter III: *Caeli ardentes solventur, & elementa ignis ardore tabescent* — "The burning heavens shall be dissolved, and the elements shall melt with fervent heat." Augustine (*3 de genesi ad lit., cap. 2, 63*) responds that by "heaven" is to be understood the air, and by "heavens" the regions of the air, as I noted in article I of this question. Or I respond with Scotus (*4, d. 43, q. 1, §. Ad argumenta, H., in solut. 2*) and Lyra (*in his postils on those passages*), following Gregory (*17 Mor., cap. 5*), that the heavens will be corrupted with respect to their accidental being, not their substantial being, since after the day of judgment the heavens will no longer move nor exert influence upon these lower things. Hence Isaiah XXX foretells: *Et erit lux Lunae, sicut lux solis, & lux solis erit septemplex, sicut lux septem dierum* — "And the light of the moon shall be as the light of the sun, and the light of the sun shall be sevenfold, as the light of seven days."

Objection II. What is moved by contrary motions is in fact corruptible, as is clearly demonstrated by experiment in sublunary things; but the heaven is moved by contrary motions, namely from east to west and from west to east, as will be apparent in the following question; therefore the heaven is in fact corruptible. I distinguish the major: concerning what is moved by altering and violent motions, I grant it; concerning what is moved by a neutral motion, such as the heaven, I deny it, as will be said in the passage cited.

Objection III. Not undistinguished astronomers report that in the year 1572 a new star was seen in Cassiopeia, which endured for two years and thereafter disappeared; but this could not have occurred without some substantial

transmutation; and what is capable of transmutation is certainly corruptible in fact, and therefore it cannot be denied that the heaven is subject to actual corruption. Augustine (*21 Civit., cap. 8*) meets this by saying it was accomplished by miracle. For he himself, following Varro, attests that the star of Venus once changed its color, size, and course in such a way that this had never happened before nor after. Hence that star foretold was miraculous, just as in the time of Hezekiah the sun went back ten degrees (*Isa. 38*), and when Christ suffered, the sun was darkened (*Luc. 23*); for it is probable that God produced that star anew to signify something great and lofty, as in Matthew II, when God led the Magi to the manger by a new star so that they might see the newborn Christ. Hence Augustine (*serm. 31 de tempore, which is found in the feast of the Epiphany*) adds that this star was a magnificent sign of the heavens proclaiming the glory of God. And sometimes God produces such a brilliance so that men may take counsel and make provision lest they henceforth follow a crooked path. This response is pious and theological. But another and philosophical response can be given with Clavius, Maurolicus, and other no less distinguished astronomers: that what appeared was not truly a star but a comet, whose matter was tenaciously and firmly joined and compacted with its form, and therefore persisted for so long and gradually diminished and afterwards vanished — which was a clear indication that it was condensed from air, clouds, and other sublunary materials, and therefore was not properly speaking a star at all. Accordingly, although it appeared to be in Cassiopeia, it was in truth below the moon — just as in the year 1617 two comets were seen, one fiery and bearded in the east, another white and silvery in the south, persisting for some months at the same distance and course as the primum mobile, so that they appeared to be in the firmament in which the fixed stars are found. I noted likewise above, in article V of this question, that clouds sometimes rise to the level of the stars, and the sun and moon are seen by us when yet the apparition is false and empty; so it must be said of that brilliance which appeared at that time to be in the heaven but was in reality beneath it and below the moon.

Article VII: Whether the Heaven is Nobler than Any Other Body

This question can be set in motion with respect to two kinds of body: an inanimate body and an animate one. Further, whether it concerns an animate body endowed with an imperfect soul, as imperfect animals are animated, or one endowed with a perfect soul, such as those that come to be solely through generation. For some, although they grant the point regarding imperfect animate beings, deny it regarding perfect ones; others except only man; still others hold commonly that the heaven surpasses in nobility any animate thing whatsoever, whether it comes to be through propagation, putrefaction, or by both modes.

Assertion I. The heaven surpasses all inanimate bodies in nobility. This is derived from the Doctor (*2, d. 14, in fine, q. 1*), who calls the heaven a body so

perfect that animation does not seem plainly incompatible with it. Indeed, together with other scholastics, he raises the question whether, if the heaven is considered to be inanimate, it is still nobler and more excellent than animate beings — which is a clear indication that he judges the heaven to surpass any inanimate body in nobility. This is finely transmitted by Augustine (*1 de vera Relig.*, c. 5, *ad finem*, & c. 37). It is proved first: nobler accidents point to a nobler and more excellent body — for accidents contribute greatly to knowledge of substance, as is said in the first place (*T. 11*). But the heaven is endowed with nobler accidents, such as light, spherical figure, circular motion, its supreme location, and the like; therefore it excels the remaining non-living bodies in nobility. Second, more excellent and distinguished effects point to a more eminent and superior cause — for it is the common saying of philosophers that from effects we come to knowledge of the cause. But the heaven possesses greater and nobler effects, as is evident (*1 Meteor.*, 1): *Oportet Mundum hunc subici superioribus lationibus* — "This world must be subject to the superior motions." For it contains, preserves, governs, and exerts influence upon these lower things, and is adorned with the most beautiful and radiant stars, and is the dwelling-place of the Blessed, in whom God is seen and enjoyed.

Assertion II. The heaven is surpassed in nobility by any animate being whatsoever, whether perfect or imperfect. This is defended by the Doctor (*1 d.* 8, q. 3, §. *Respondetur*; and *d. 13*, q. un., §. *Alia est, ante M.*; and *Quol. 1*, art. 1, sub G.; and *4 Rep.*, d. 49, q. 7) against Pererius (*1, 2, cap. 6*), Báñez (*1 p.*, q. 3, a. 3), and certain others. It is urged first from Ecclesiastes IX: *Melior est canis vivus leone mortuo* — "A living dog is better than a dead lion." For no reason other than that the living dog is animate and the dead lion inanimate. But the heaven, as was said in article IV of this question, is inanimate; therefore it is ranked below any animate thing. Second, from Augustine (*15 Trin.*, c. 4, & *11 Civit.*, c. 16, & *l. de vera religione*, c. 55): whatever living substance there is is rightly preferred by the law of nature to any non-living substance. And in the first book of the two souls, he says that a fly, because it lives, is nobler than the sun. Third, just as it is better to be than not to be, so it is better and more perfect to live than not to live. For the grade of life is preferred to the grade of nature; and likewise vital, animal, and rational operations excel natural and non-vital ones. Moreover, the soul is a more perfect form, and living things are moved from within, while the heavens are moved from without, as will be shown below; therefore any animate things surpass them in nobility.

Objection I. Aristotle (*1 Caeli*, T. 16, & *1 de partibus animalium*, c. 1) calls the stars and celestial orbs more excellent than all things that fall under the senses. He intimates the same (*2 Caeli*, c. 3, T. 6). And previously, (*6 Eth.*, cap. 7), he had premised that there are other things far more divine than man, such as what we behold with our eyes, namely the celestial bodies. Therefore in Aristotle's school the heaven is ranked above all sublunary things, both living and non-living. I respond: if Aristotle held the heaven to be animate — as he appears to do in the

opinion of many — he no doubt maintained that the heaven itself is nobler than all created living things; but if he thought it to be inanimate, the testimonies he adduced are capable of this interpretation: that the heaven surpasses animate things, even man, in nobility, if it is taken for the aggregate of the celestial orb and the intelligence that assists it, but not if it is taken precisely for the celestial body alone.

Objection II. A cause is nobler than its effect (*5 Met.*, 1 & 2). But the heaven is the cause of living things, and chiefly of man (*2 Phys.*, 26), who excels all sublunary living things; therefore the heaven is superior both to inanimate and to animate things. I distinguish the major: concerning a total and principal cause, I grant it; concerning a partial and less principal cause, I deny it — as is evident in the case of the intelligible species, which is a partial and less principal cause of the act of intellection, yet is more ignoble and inferior to the act of intellection itself. But the heaven is only a dispositive cause of animate beings. For, as will be said elsewhere, the heaven is not the productive and efficient cause of their souls; rather, given the prior dispositions and suitable preparations of their bodies, God draws forth and produces their souls from the potency of their matter as informing, perfecting, and completing principles.

Article VIII: How Many Heavens There Are

The opinions of philosophers and astronomers differ and conflict in establishing and settling the number of celestial bodies and orbs. For Chrysostom (*hom. 4 in Genesin*) and Andreas Caesalpinus (*3 de orbibus*, q. 4) hold that there is only one heaven containing stars which pass and move through it like birds in the air and fish in the sea, through its cavities and channels. Some, supported by Orbellus (*2, d. 14*), hold that there are three heavens: the aerial, the ethereal, and the empyrean. Aristotle (*12 Met.*, T. 47, cap. 4, *Summa* 2) enumerates eight heavens. Certain recent thinkers enumerate twelve; and Basilides, as cited by Augustine (*in the catalogue of heresies*, heresy 4), counts three hundred and sixty-five. The common opinion of astronomers and theologians, however, holds that there are ten mobile heavens, to be enumerated and named below.

Note first that "heaven" is sometimes used for the entire celestial globe comprehending all the celestial orbs; this is how the divine chronicler of Genesis speaks in chapter I: *In principio creavit Deus caelum & terram* — "In the beginning God created the heaven and the earth." And Aristotle titles his books *On the Heavens and the World*, as does the author of the *Sphere* in his little book. At other times, however, "heaven" is used for individual celestial orbs, in which sense sacred scripture not infrequently speaks of the heaven in the plural — notably Psalm CXLIV: *Laudate eum Caeli Caelorum* — "Praise him, O heavens of heavens." And in the preface of the Mass the Church sings: *Caeli Caelorum* — "the heavens of heavens."

Note second that the number of the mobile heavens has been discerned by astronomers from the number of their motions. Hence they posit as many mobile heavens as there are diverse motions of those celestial orbs, since the same body cannot be set in motion by diverse motions. Now ten diverse motions have been found by astronomers in the celestial bodies, as Scotus (2, d. 14, q. 2) notes above all others, and for that reason they affirm that there are ten heavens.

Note third that stars fall into two classes. Some are called fixed because, placed in the firmament or the starry heaven, they always maintain the same proximity or distance. Others are called wandering because they do not always maintain the same distance or proximity but sometimes approach and sometimes recede, as we observe every day in the sun and moon; and such stars are called Planets.

Assertion I. There is not only one heaven. This is held by the Doctor (*loc. nuper alleg.*). It is proved first from sacred scripture. Psalm CXLVIII: *Laudare Dominum de caelis* — "Praise the Lord from the heavens." Ecclesiasticus XXIV: *Ego feci in caelis ut oriretur lumen indeficiens* — "I caused an unfailing light to rise in the heavens." And Ephesians IV: *Qui ascendit super omnes caelos* — "Who ascended above all the heavens." Second, from the holy Fathers — Augustine (10 in *Gen.*, cap. 29), Ambrose (2 *Hexam.*, 2), Damascene (2 *fidei*, 6), and others cited by recent writers — who defend the foregoing assertion. Aristotle lends support (2 *Caeli*, 59, & 12 *Met.*, Tit. 48), enumerating as many intelligences or angels as there are mobile heavens. The astronomers, both ancient and modern, give their assent, as cited by the Coimbrans (2 *Caeli*, c. 5, q. 1, art. 1) and Ruuius (*ibid.*, q. 2). Third, the plurality of heavens is derived from the plurality and diversity of motions, as I noted above in the second note. But the motion of the heaven is not one, as we observe every day in the sun, moon, the other planets, and the stars; therefore the heaven is not one but manifold.

Assertion II. Ten mobile heavens are enumerated, which our Gadius (*in com. Quol. II, fol. 117, colum. tertia*) numbers and names as follows.

X. The primum mobile, which is called the crystalline or watery heaven. IX. The zodiacal heaven, so called because its motion takes place above the poles of the zodiac and along its degrees; which motion, although slow, is nevertheless true and real. VIII. The firmament, which is also called the starry heaven, because the fixed stars are found in it. VII. The heaven of Saturn. VI. The heaven of Jupiter. V. The heaven of Mars. IV. The heaven of the Sun. III. The heaven of Venus. II. The heaven of Mercury. I. The heaven of the Moon.

That this assertion is most true and most received is transmitted by Racon (*disp. unica de caelo, sect. 1*). And it is consistent with Scotus, who, although in both works (2, d. 14, q. 2) he enumerates nine mobile heavens, would also admit a tenth; for he grants the ninth on the basis of the ninth motion discovered by astronomers — namely retrograde motion — and therefore would equally grant

a tenth on the basis of another motion, which is the motion of trepidation or approach and recession, discovered by later astronomers who are equally distinguished and experienced in that art. For the same Doctor (*3, d. 4, q. un., near the end, L.*) in a similar difficulty says that the experts are to be believed. Since, therefore, more recent astronomers have by long and careful investigation discovered the tenth motion, they have discovered a tenth heaven as well. Nor should this surprise anyone, seeing that Christopher Columbus by a long voyage discovered a new world which had previously been unknown to us. Thus from ten distinct and diverse motions, ten distinct and diverse celestial spheres and orbs are rightly inferred, which it is fitting to enumerate and explain individually. The primum mobile is moved by the motion of rapture, by which it draws all the lower orbs with it and completes its course in the space of twenty-four hours, in which the natural day consists. The zodiacal heaven is moved by the motion of trepidation and completes its course in the interval of thirty-six thousand years. The starry heaven completes its motion in one hundred years. The heaven of Saturn in thirty years. The heaven of Jupiter in twelve years. The heaven of Mars in two years. The heavens of the Sun, Venus, and Mercury each in approximately one year. And the heaven of the Moon each month.

Assertion III. Beyond the ten heavens enumerated above, an eleventh must be admitted, immovable, which is called the empyrean. Scotus intimates this (*passu pract., §. Ad argumenta, in solut. 1*), and all theologians hold it together with the Master (*ibid.*). It may be urged thus: there must be admitted that heaven to which Christ the Lord ascended (*Ephes. 4*) and in which he sits at the right hand of God the Father; but that heaven in which the Savior exists is called the empyrean; therefore an eleventh heaven must be admitted. Furthermore, two cities exist — one of the damned, another of the Blessed — which is mentioned by John (*Apoc. 21*): *Civitas in quadro posita est* — "The city is set in a square"; and this city or dwelling-place of the saints, in which the Blessed clearly see and enjoy God, is called the empyrean and is considered immovable. For if this heaven were to move, the Blessed who dwell in it would also be moved; yet it is not fitting that they should be moved and agitated, since they rest from their labors (*Apoc. 6*) and have reached their term, as Scotus and the scholastics teach.

Objection I against the first assertion. Aristotle (*12 Met., T. 48*) writes that a heaven exists for the sake of the motion of a star, and in the same heaven there are many stars; for we read in Genesis I that God made the sun, the moon, and the stars, and placed them in the firmament. Therefore there is only one heaven in which all the stars exist. Confirmation I: one and the same is the motion of all the celestial orbs, as is visible to the eye; therefore there is only one heaven. Confirmation II: entities are not to be multiplied without necessity (*1 Phys., 52*); but there is no necessity compelling us to posit more heavens, since all the stars, both fixed and wandering, can exist in one and the same heaven, namely the firmament; therefore only one heaven is to be affirmed. I respond that there is

indeed one reason why a heaven exists on account of a star, but this is not the precise and total cause; for there are many and diverse heavens to cause the diverse effects and influences upon these lower things, as will be apparent below. That this is so is clearly established, since Aristotle in the first assertion cited affirms that there are eight mobile heavens. To the passage from Genesis, the Doctor (*cit.*) responds that there "firmament" is taken for the entire celestial globe situated between it and the elemental orbs. Lyra indicates the same, saying that "firmament" is taken as containing the other lower spheres in which the Planets shine. To Confirmation I, I say there is one common motion of the primum mobile by which all the other lower orbs are swept along, but there are several proper motions by which the lower orbs themselves revolve, as was shown above. To Confirmation II, the major is granted and the minor denied, as was proved in the second assertion.

Objection II against the second assertion. It is read in 2 Corinthians XII that Paul was caught up to the third heaven, which is the empyrean, where he heard secret words that it is not lawful for man to speak; therefore there are only three heavens. I respond that the sacred text enumerates three heavens there without denying that there are other and more; for an argument drawn from negative authority does not conclude. Or, better, I say that by the three heavens are to be understood the air, the entire globe of mobile celestial bodies, and the empyrean. Or, as Lyra (*in his postil*) expounds it, by the third heaven the empyrean is taken, by the second the crystalline, and by the first the sidereal, comprehending the firmament and the remaining lower celestial spheres. Augustine (*12 de gen. ad lit.*, 6, 7) interprets the three heavens as three modes of vision: corporeal, spiritual, and intellectual.

Objection III against the same assertion. If heavens are multiplied and exceed the number eight, which Aristotle posited especially on account of the retrograde motion and the motion of trepidation observed by later astronomers, those later astronomers may have been mistaken. For that motion is barely perceptible and can be produced by the angel assisting and moving that heaven; and indeed so great an interval and distance intervenes that it cannot be reached. All the more so because it is said to occur at the rate of one degree in a hundred years. And what astronomer lives long enough to be able to observe the terminus of that motion, since his life is so brief that he cannot reach its goal? Therefore no other heavens beyond the eight handed down by Aristotle and other philosophers seem to be admissible. I respond that by careful investigation and prolonged observation, distinguished and foremost astronomers have truly discovered and established that motion. For if they are furnished with suitable instruments elaborated with such skill that they have arrived at an evident knowledge of it, even though that motion is the slowest and the smallest, greater credence is to be given to them than to others not much exercised in that art; and the first discoverers handed it on to their successors, and so in turn these have handed it on to us, nor ought it to seem

strange to anyone, since not all things were known to our predecessors but were disclosed with the passage of time, as is established in the case of certain small matters in the correction of the Council of Nicaea and subsequently of Gregory XIII. Since, therefore, three motions are observed in the firmament, produced not by the angel assisting and moving that heaven but by other angels deputed to the higher spheres mentioned, and since it is the case that each celestial body has its own motion distinct from the rest — from which their number and influence are derived — seeing that every hundred years the greatest revolutions take place in sublunary things, and that after the great Platonic year all things will return to their starting-point, as certain philosophers cited by Augustine (*12 Civit.*, c. 13) and mentioned by Scotus (4, d. 43, q. 3, §. *Sciendum. A.*) affirm.

Article IX: Whether the Heavens and the Stars are Distinct in Species

Two doubts are raised in the present article: the first is whether the heavens differ from one another in species; the second is whether the stars, both among themselves and from the heavens in which they reside, obtain a specific distinction. On the first point, Averroes (*2 Caeli*, com. 48), Jandun (*ibid.*, q. 12), and Durand (2, d. 14, q. 2) deny a specific difference among the heavens; the Parisians (*2 Caeli*, q. ult.), Joannes de Magistris (*ibid.*, q. 4), and Richard (2, d. 14, a. 3, q. 5) affirm it. On the second point, two opinions likewise prevail: the former is defended by Tartaretus (*2 Caeli*, q. 2, dub. 3), Ruuius (*ibid.*, c. 7, q. 1), and Molina (*tr. de operibus Sex dierum*, disp. 15), who establish a specific distinction between the orbs and the stars existing in them. The latter is transmitted by Racon (*disp. de caelo*, q. 2, a. 3), Mayronis (q. 8), and many others, from whom Scotus (2, d. 14, q. 2, & in *Report. ibid.*) does not seem to depart, holding that stars and the orbs in which they inhere enjoy the same species, whether those stars be fixed or wandering.

Assertion I. Celestial bodies differ from one another in species. This is not at variance with Scotus (*loco mox alleg.*). It is urged first: distinct effects in species, and diverse passions, motions, and locations, point to distinct causes, essences, and principles in species — as is established in these sublunary things, both animate and inanimate, whose diverse effects, powers, and properties lead us to knowledge of their specific distinction. But the celestial orbs have distinct effects, passions, motions, and locations: one humidifies, another desiccates; one heats and another cools; and so on — all of which assuredly indicate and mark out for us the specific distinction that exists among them. Second, the sublunary orbs differ from one another in species, as is evident in the orbs of fire, air, water, and earth; therefore the same must be asserted of the celestial orbs, since the same reasoning holds in both cases. Paul intimates this clearly enough (*1 Cor. 15*), where, asserting a specific difference among men, cattle, birds, and fish, he asserts the same to hold between celestial and terrestrial bodies, and even among the celestial bodies themselves, as the author of the work on faith addressed to Peter (c. 3) appears to explain, and as Lyra (*ibid. in Postil.*) does not

dispute. To this is added the argument of the Seraphic Doctor (2, d. 14, a. 2, q. 1), derived from the four kinds of causes, which, being lengthy though beautiful, may be seen in him.

Assertion II. The Planets obtain specific distinction among themselves but are identified in species with the orbs to which they are assigned, and the same is to be held of the fixed stars. Scotus does not depart from this (*ubi supra*), but indicates it (4, d. 49, q. 15, §. *Ad primum. C.*). The assertion is tripartite.

The first part, concerning the specific distinction of the Planets, is readily established. For in the first assertion it remains proved that the celestial orbs differ from one another in species; but the Planets reside in distinct orbs; therefore, according to the specific distinction of their orbs, they themselves likewise differ from one another in species. Moreover, the same reasoning holds for the Heavens as for the Planets. For the Planets have diverse and distinct effects and influences: Saturn moves man to sadness and avarice; Jupiter to joy and liberality; Mars to war and discord; Venus to peace and concord; and so on for the rest.

The second part is proved from Aristotle (2 *Caeli*, c. 7, T. 41), who says that the stars share the same nature with the orbs in which they inhere. The argument is adduced by the Doctor (*passu proxime alleg.*): the stars are the dense parts of the celestial orbs; but rare and dense do not change the species. Moreover, the same influences, effects, and passions proceed from the Planets and from the orbs in which they exist; therefore it is plainly established that they are of the same species as those orbs.

The third part is also settled. For the fixed stars are the dense and compact parts of the starry heaven or firmament, and the remaining parts in which no stars appear are the rare parts; but, as I said, dense and rare, like more and less, do not vary the species; therefore the fixed stars share the same specific nature with the heaven in which they inhere.
